On trucks so equipped, the radiator automatic shutter thermostat maintains coolant temperature above the engine thermostat setting, opening or closing the shutter as necessary to maintain engine temperature at a pre-determined setting. The W-and L-Series trucks and the P-5000-Series trucks use a shutter that directly is operated by a thermostat linked to the shutter. On some trucks with air brakes, an air cylinder actuates the shutters. On other trucks with vacuum brakes, a vacuum cylinder

actuates the shutters. Control of the air or vacuum cylinder is maintained by a shutterstat, which is a thermostatically controlled valve. To determine the cause of automatic shutter malfunction, the air or vacuum cylinder and shutterstat or the thermostat power element and linkage can be tested separately.

AIR CYLINDER TEST

1. To test air cylinder operation, release all air pressure from the brake system and disconnect the air line at the air cylinder. Springs in the shutter assembly should completely open the shutters.
2. If shutters remain closed, the cause may be either the air cylinder is not working, cylinder linkage is maladjusted, the shutters are binding, or shutter spring is broken.
3. Apply 90 psi air pressure to the air cylinder. The shutters should close completely, providing the linkage is adjusted correctly and the shutters are not binding. Check the air cylinder for leaks. Replace or repair the air cylinder if leaking, or the shutters are not completely closed.

VACUUM CYLINDER TEST

1. To test vacuum cylinder operation, disconnect the vacuum line to the vacuum cylinder. Springs in the shutter assembly should completely open the shutters.
2. If shutters remain closed, the cause may be either the vacuum cylinder is damaged, cylinder linkage is maladjusted, or the shutters are binding.
3. Connect a temporary line from the truck vacuum system to the vacuum cylinder. Start the engine. Shutters should close completely when vacuum reaches normal level, providing the linkage is adjusted correctly and the shutters are not binding. Check the vacuum cylinder for air leaks. Replace the vacuum cylinder if leaking or if the shutters do not close completely.

THERMOSTATICALLY CONTROLLED SHUTTER TEST (W-L-SERIES)

1. Make sure that the linkage is properly adjusted and free from binding.
2. Check to see if shutters are opening at desired temperature range.

If the shutters are opening at the desired temperature range, but the engine is overheating, the problem may be the engine thermostat, fan belt, water pump or a clogged cooling system.

If the shutters are not opening at the desired temperature range, remove the control assembly and measure the distance from the gasket surface to the end of the power element. The distance should be 2-15/16 inches. If not, adjust it until the proper distance is obtained. If it is properly adjusted, check the number stamped on the end of the power element. Number 383 will open at 170 degrees, Number 137 at 175 degrees and Number 380 at 180 degrees.

ADJUSTMENTS

RADIATOR AUTOMATIC SHUTTER ADJUSTMENT

When operating properly, the radiator automatic shutters will remain fully closed until the engine reaches normal operating temperature. An adjustable feature is provided in the shutter linkage of some models to set the shutters at the fully closed position.

AIR OPERATED SHUTTER—C-SERIES

1. Apply air pressure (approximately 90 psi) to the air cylinder for the full stroke of the piston to close the shutter blades.
2. Loosen and back-off nut B (Fig. 1).
3. Adjust nut A (Fig. 1) to provide a slight pressure of the rubber vane seals on the shutter blades.
4. Tighten nut B.

VACUUM-OPERATED SHUTTER—C-750-800

1. Apply normal vacuum to the vacuum cylinder to close the shutter blades.
2. Check for a slight pressure contact of the rubber vane seals on the shutter blades.
3. If adjustment is required, loosen nut B (Fig. 1) and remove nut A from pin.
4. Screw nut A (Fig. 1) in or out to increase or decrease the closed pressure contact of the rubber vane seals.
5. Replace nut A on pin and apply vacuum to the cylinder. Recheck the blade contact.
6. After the correct adjustment, tighten nut B.

VACUUM-OPERATED SHUTTER—C-SERIES EXCEPT C-750-800

1. Apply vacuum to the vacuum cylinder to close the shutter blades.
2. Loosen and back-off nut B (Fig. 1).
3. Adjust nut A (Fig. 1) to provide a slight pressure of the rubber vane seals on the shutter blade.
4. Tighten nut B.

THERMOSTATICALLY OPERATED SHUTTER—LN-6000-7000

1. When the engine is cold, loosen jam nut B shown in Fig. 1.
2. Turn nut A until slack in the cable is taken up and shutter blades are in the closed position.
3. Tighten jam nut B.

THERMOSTATICALLY OPERATED

1. When the engine is cold, loosen jam nuts B shown in Fig. 1.
2. Turn nut A until slack in linkage is taken up with the shutter blades in the closed position.
3. Back off nut A 1 to 2 turns.
4. Tighten jam nuts B.

VACUUM-OPERATED SHUTTER—F AND B-6000-7000

1. Loosen the jam nut (Fig. 1) and disconnect the swivel nut from the trip lever.
2. Apply vacuum to the vacuum cylinder to move the trip lever to the shutter blade closed position.
3. Move the shutter rod upward to obtain a slight pressure contact of the vane seals on the shutter blades. Then, adjust the swivel nut to match the hole in the trip lever.
4. Connect the swivel nut to the trip lever and tighten the jam nut.

THERMOSTAT OPERATED SHUTTER—P-SERIES

1. When the engine is cold, loosen the nut B shown in Fig. 1.
2. Adjust nut A to obtain a slight pressure contact of the shutter blade rubber vanes.
3. Tighten nut B against nut A, taking care not to let nut A turn.

VERNATHERM THERMOSTATICALLY OPERATED SHUTTER L—W-SERIES

1. With the engine temperature below 150 degrees F, loosen the jam nut on the shutter control rod (Fig. 1).
2. Adjust the turnbuckle on the shutter control rod until the shutter control assembly plunger bottoms.
3. Back off the turnbuckle 1 to 1 1/2 turns. During very cold weather operation, the turnbuckle may be backed off 3-4 turns. If it is backed off 3-4 turns, it will have to be readjusted to 1 to 1 1/2 turns if and when warm weather operation is encountered.
4. Tighten the jam nut.
5. Operate the engine and see if the shutter opens as the engine reaches operating temperature. The full open position of the shutter blades is at an angle of 60 degrees— 70 degrees to the radiator.

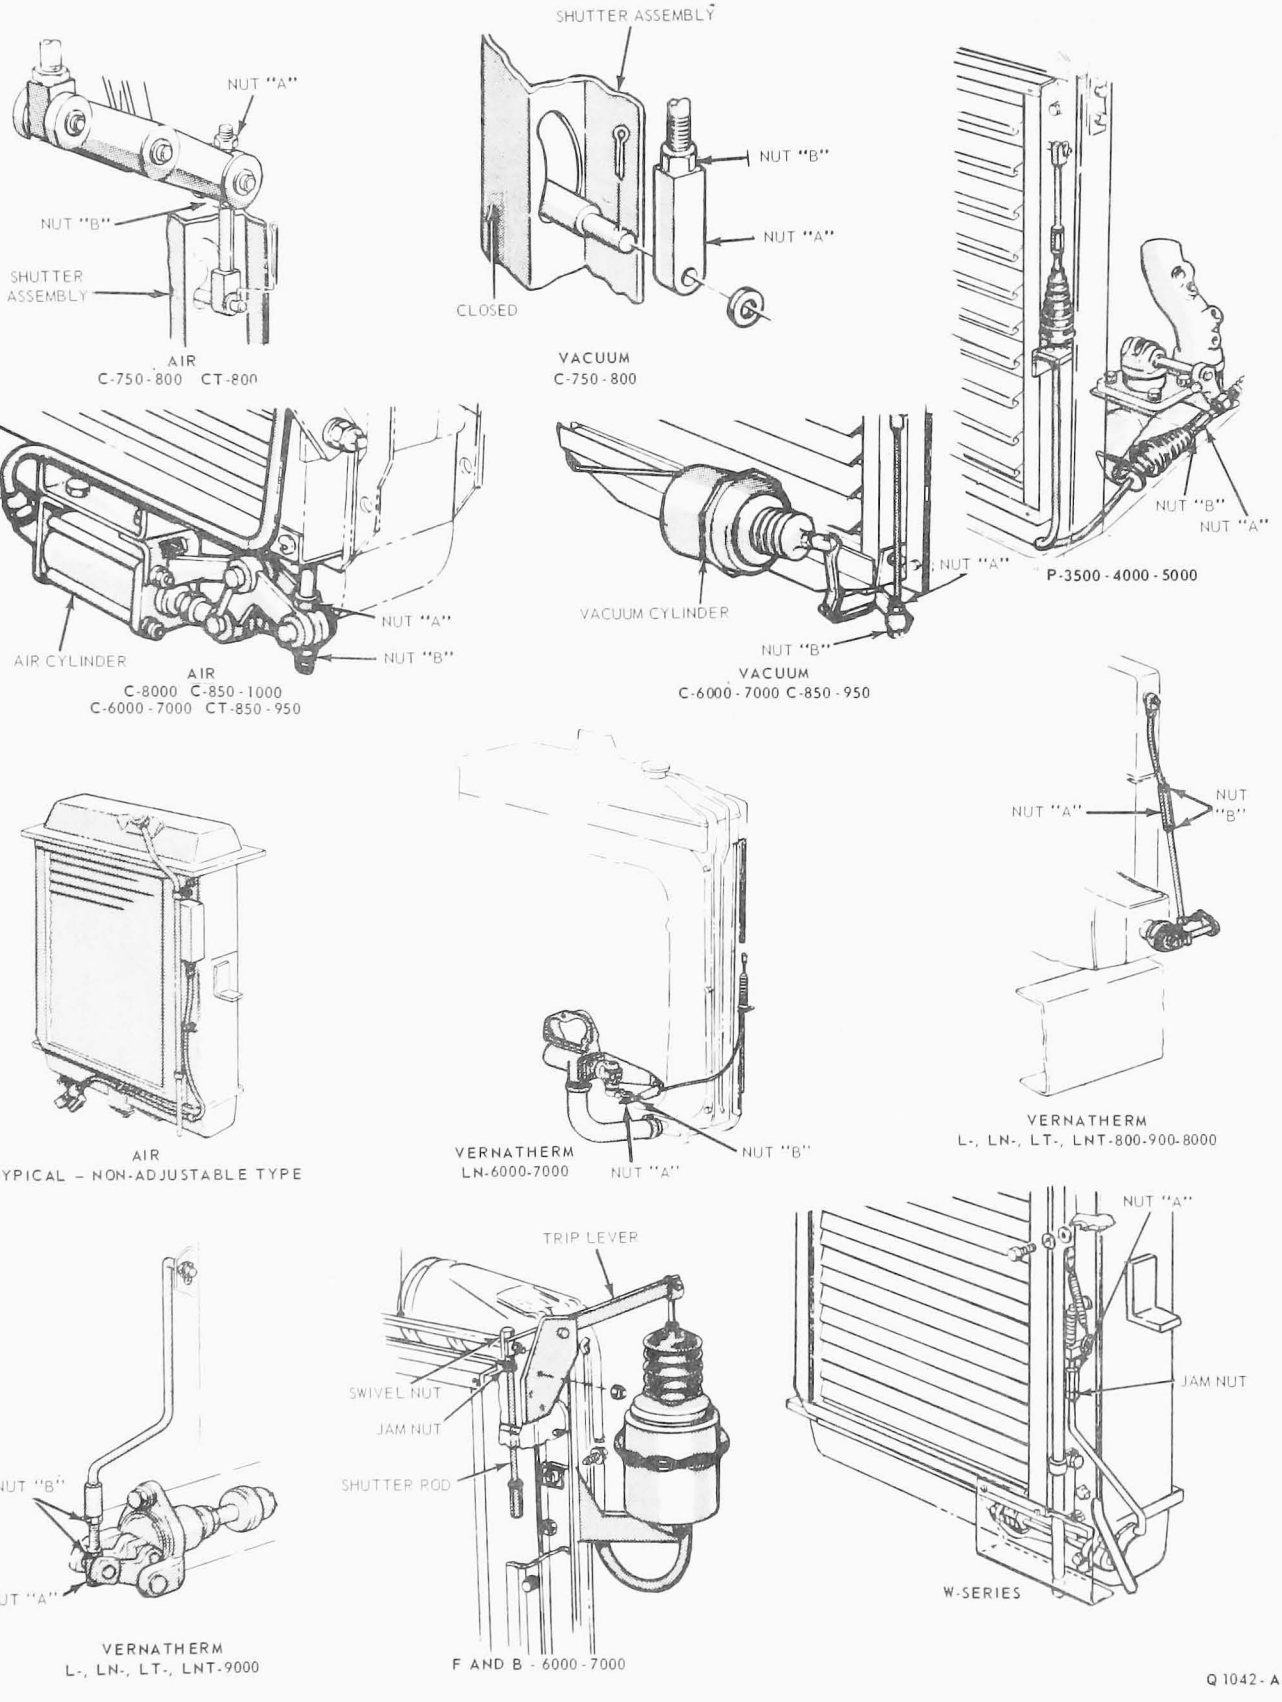

FIG. 1 Automatic Shutter Adjustment Points

REMOVAL AND INSTALLATION

AIR CYLINDER

700-800 SERIES TRUCKS—GASOLINE ENGINES

Removal

The 700-800 Series air cylinder installations are shown in Fig. 2.

1. Shut off the air control valve. Disconnect the air line at the air cylinder.
2. On C-Series trucks, remove the cotter pin, washer and clevis pin connecting the air cylinder rod to the linkage.
3. Remove the air cylinder retaining bolts and remove the air cylinder.

Installation

1. If a new air cylinder is being installed, transfer the nut(s) and air fitting to the new air cylinder.
2. Install the air cylinder and torque the retaining bolts to specifications.
3. On C-Series trucks, connect the air cylinder rod to the linkage with the clevis pin, washer and cotter pin.
4. Connect the air line to the air cylinder and open the air control valve. Adjust the shutter linkage as described in this Part, Adjustments.

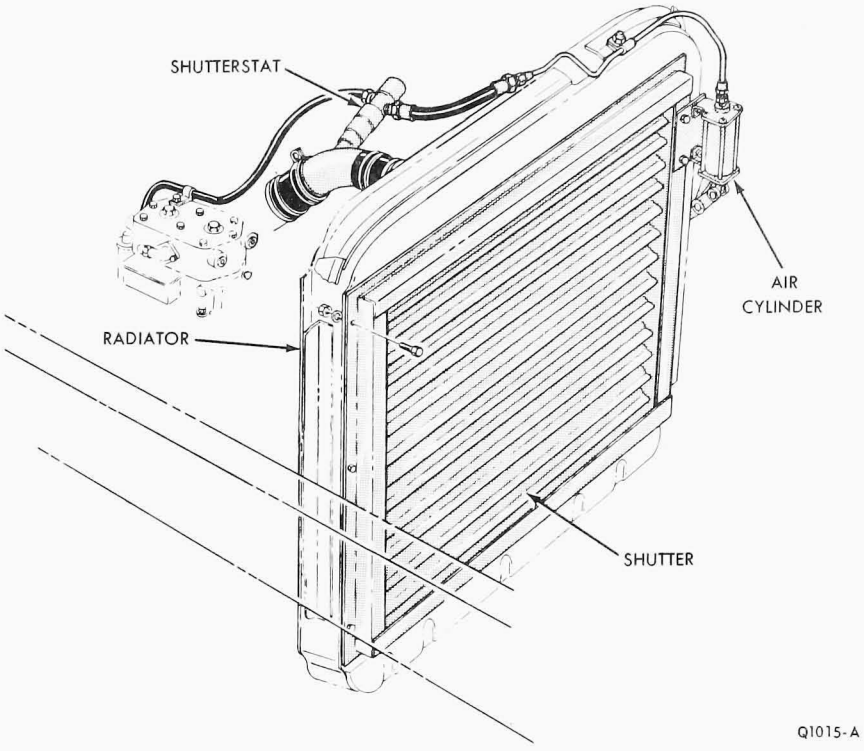

FIG. 2 Typical C-Series Air-Operated Radiator Shutter Assembly—Gas Engine

800-900 SERIES TRUCKS—GASOLINE ENGINES

Removal

The air cylinder installations are shown in Figs. 3 and 4.

1. Shut off the air control valve. Disconnect the air line at the air cylinder.
2. Disconnect the shutter operating bellcrank at the air cylinder.
3. Remove the air cylinder retaining bolts and remove the air cylinder.

Installation

1. If a new air cylinder is to be installed, transfer the air fitting to the new cylinder. Install the air cylinder on the mounting bracket. Position the shutter operating bellcrank on the cylinder and install the retaining nut.
2. Connect the air line to the air cylinder and open the air control valve. Adjust the shutter linkage as described in this Part, Adjustments.

CUMMINS DIESEL AND DETROIT DIESEL ENGINES

Removal

The air cylinder installations are shown in Figs. 2 through 5.

1. On L-, LN-, LT-, LNT-Series trucks, open the hood assembly. On C-Series, tilt the cab.
2. Shut off the air control valve. Disconnect the air line at the air cylinder.
3. Disconnect the shutter operating bellcrank at the air cylinder.
4. Remove the air cylinder retaining bolts and remove the air cylinder from the mounting bracket.

Installation

1. If a new air cylinder is to be installed, transfer the air fitting to the new cylinder.
2. Install the air cylinder on the mounting bracket and torque the retaining bolts to specifications.
3. Connect the air hose. Position the shutter operating bellcrank on the cylinder and install the retaining nut.
4. Open the air control valve. Start the engine and check the shutter operation.
5. Close the hood assembly.

VACUUM CYLINDER

GASOLINE ENGINES

Removal

Vacuum cylinder installations are shown in Figs. 6 and 7.

1. Disconnect the vacuum line at the vacuum cylinder.
2. On C-Series trucks remove the cotter pin, washer and clevis pin and disconnect the vacuum cylinder rod from the shutter linkage.
3. Remove the retaining bolts and lift off the vacuum cylinder.

Installation

1. If a new vacuum cylinder is being installed, transfer the rod nut(s) and vacuum fitting to the new vacuum cylinder.
2. Install the vacuum cylinder and torque the retaining bolts to specifications.
3. On C-Series trucks connect the vacuum cylinder rod to the shutter linkage with clevis pin, washer and cotter pin.
4. Connect the vacuum line to the vacuum cylinder. Adjust the shutter linkage as described in this Part, Adjustments.

SHUTTERSTAT

Whenever changing the shutterstat to a higher or lower temperature range,

the engine thermostat must be changed accordingly to a higher or lower range.

Removal

1. Partially drain the radiator so that the coolant level is below the shutterstat assembly.

   On an air operated system, close the air control valve.
2. Disconnect the air hoses from the shutterstat. Remove the shutterstat.

   Do not attempt to adjust the shutterstat. It should be replaced if it is not operating properly.

Installation

When installing a new shutterstat, be sure the difference in temperature calibration between the engine thermostat and the shutterstat is maintained or the shutters will be ineffective.

1. If a new shutterstat is to be installed, remove the fittings from the old shutterstat. Apply water-resistant sealer on the threads of the fittings and install the fittings in the new shutterstat.
2. Apply water-resistant sealer on the mounting threads of the shutterstat. Install the shutterstat. Connect the air hoses to the shutterstat.
3. Fill the cooling system with coolant and bleed the system.
4. Start the engine and check the shutter operation. Check the system for leaks and correct coolant level.

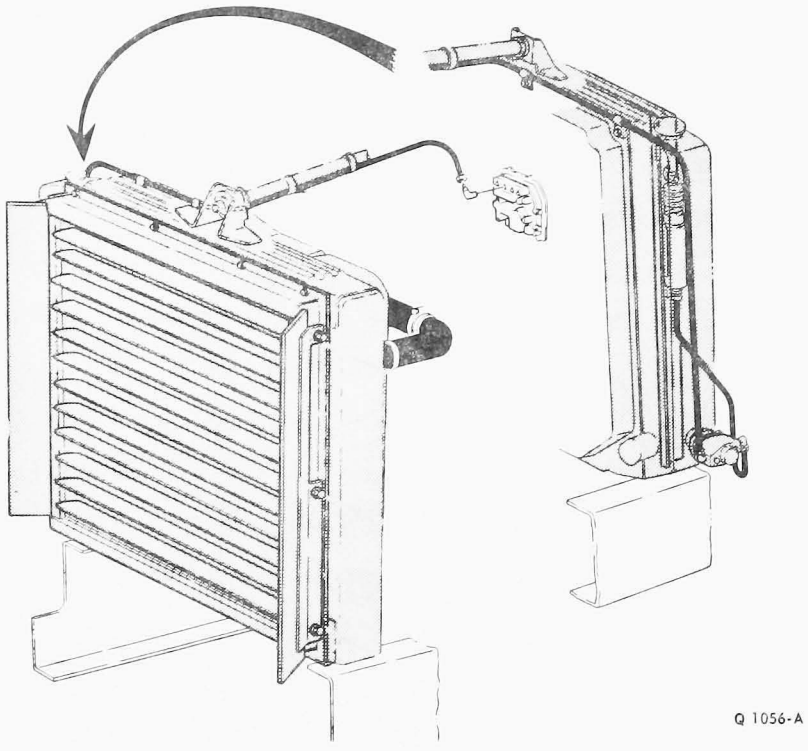

FIG. 3 Typical L-Series Air-Operated Radiator Shutter Assembly—Gas Engines and 6V-53 Diesel

SHUTTER ASSEMBLY

C-SERIES TRUCKS—GASOLINE ENGINES

Removal

Refer to Figures 4, 6 and 7.

1. On an air operated system, close the air control valve. Disconnect the air line at the air cylinder.

   On a vacuum operated system, disconnect the vacuum line at the vacuum cylinder and at the shutterstat.
2. Disconnect the throttle linkage ahead of the radiator and swing to one side. Remove the bolt(s) retaining the air or vacuum line on the radiator and/or shutter assembly.
3. Remove the bolts, nuts and washers retaining the shutter assembly to the radiator.
4. Lift the shutter assembly from the truck.

Installation

1. If the shutter is being replaced, transfer the air or vacuum cylinder, linkage and weatherstrip to the new shutter.
2. Position the shutter assembly on the radiator and install the retaining bolts, nuts and washers. Adjust the radiator shutter linkage as described in this Part, Adjustments.
3. Connect the air or vacuum line. Connect the throttle linkage.
4. On an air operated system, open the air control valve.
5. Start the engine and check the shutter operation. Check the system for leaks.

W-SERIES TRUCKS—ALL ENGINES

Removal

1. Remove the radiator (refer to Part 27-04, Removal and Installation).
2. Remove the cotter pin from the shutter control rod (Fig. 8) and remove the shutter control rod from the shutter control assembly lever.

   Remove the shutter control assembly cover plate.
3. Remove the bolts, nuts and washers from each side of the shutter assembly. Disconnect the overflow hose from the radiator cap housing and remove the shutter assembly.

Installation

1. If the shutter assembly is being replaced, transfer the overflow hose and clamps from the old shutter assembly.
2. Install the shutter assembly on the radiator.
3. Insert the shutter control rod in the shutter control assembly lever and install the cotter pin.
4. Adjust the control rod (refer to Adjustments).
5. Install the shutter control assembly cover plate and connect the overflow hose to the radiator cap housing.
6. Install the radiator (refer to Part 27-04, Removal and Installation).

L-LN-LT-LNT-SERIES—ALL ENGINES

Removal

1. Unlock and tilt hood assembly forward.
2. On air operated system, close the air control valve. Disconnect the air line at the air cylinder.

   On thermo operated system (Figs. 9 through 11), remove cotter pin attaching shutter control linkage to bellcrank. Disconnect shutter control linkage from bellcrank. Remove linkage attaching screw as necessary.
3. Remove the bolts retaining the shutter assembly to the radiator.
4. Lift the shutter assembly from the truck.

Installation

1. Position the shutter assembly in front of the radiator and install

attaching bolts.
2. On air operated system, connect the air line and open air control valve.

On thermo operated system, connect the air line and open air control valve.
3. Adjust the shutter assembly as described in Adjustments, as necessary.
4. Close and lock hood assembly.

MAJOR REPAIR OPERATIONS

AIR CYLINDER

Some air operated shutter installations are equipped with air cylinders that are replaced as a unit. Other installations have air cylinders which can be disassembled and repaired. The instructions below apply to the repairable type air cylinder.

Disassembly

The air cylinder assembly is shown in Fig. 12.

1. Remove the air cylinder. Remove the four long bolts and the nuts retaining the air cylinder ends to the cylinder (Fig. 12). Slide off the air inlet end and the cylinder housing.
2. Loosen the lock nut at the actuating arm end of the piston and unscrew the piston from the actuating arm. Remove the lock nut, piston assembly, return spring, spring seat washer, felt, and gasket.
3. Remove the nut and lock washer from the piston cup retainer. Remove the cup retainer, cup, and lift off the seal.
4. Remove the two screws and lock washers retaining the dust cap retainer. Remove the dust cap, felt, and washer.

Assembly

1. Install the dust cap washer, new felt, dust cap, dust cap retainer and the screws and lock washers. Do not tighten the retaining screws at this time.
2. Install a new gasket, felt, and spring seat washer on the actuating arm bracket end plate.
3. Install the return spring on the piston, insert the piston assembly through the actuating arm end plate, and install the lock nut.
4. Install the seal in the piston groove, the piston cup, cup retainer, and lock washer and nut.
5. Screw the piston assembly into the actuating arm and tighten the lock nut.
6. Tighten the dust cap retaining screws.
7. Coat the cylinder and piston cup with a high temperature grease (Litholene multipurpose grease or the equivalent). Install the cylinder housing. Install the O-ring on the air inlet and plate and place the plate on the cylinder housing.
8. Install the four bolts, position the mounting bracket on the bolts, and install the lock washers and nuts.

SHUTTER ASSEMBLY

Disassembly

1. On C-Series Trucks, disconnect the linkage from the shutter pin and remove the air or vacuum cylinder and linkage.
2. Place the assembly on a work bench and remove the bolts and washers retaining the shutter blades to the housing.
3. Remove the shutter blade assembly from the housing.
4. Remove the shutter blade return springs.
5. Remove the retaining wires from the end brackets. Remove the E clips from the blade actuating bracket. Remove the brackets from the shutter blades.

Assembly

1. If the oilite bearings are damaged either replace or rebush the bearings. Repair or replace damaged shutter blades.
2. Install the washers on the shutter blades. Install the brackets, retaining wires, and E clips on the shutter blades.
3. Position the shutter blade assembly on the housing with the actuating arm rod through the shutter housing and into the cylinder arm.
4. Install the blade retaining screws and washers.
5. On the C-Series truck, install the air or vacuum cylinder and connect the linkage.

PART 28-01 Starting System General Service

GENERAL INFORMATION

The function of the starting system is to crank the engine at a speed fast enough to permit the engine to start. Heavy cables, connectors, and switches are used in the starting system because of the large current required by the starter while it is cranking the engine. The amount of resistance in the starting circuit must be kept to an absolute minimum to provide maximum current for starter operation. Loose or corroded connections, relay contacts, or partially broken cables will result in slower than normal cranking speeds, and may even prevent the starter from cranking the engine.

In cases of starting system trouble, the owner may have discharged the battery before calling for assistance. At the time the trouble occurs, the owner is more interested in getting the engine started than in knowing the cause of the trouble. A road service procedure is presented to aid the service technician in such cases of starting trouble. Once the engine is started, be sure to follow diagnosis procedures in order to locate the cause of the starting difficulty. The road service is not a part of the diagnosis procedures.

Refer to the Truck Diagnosis Manual, Form FD-7962-70T, for diagnosis information and procedures.

Refer to the Wiring Diagrams Manual, Form 7795P-73, for electrical schematic wiring diagrams and the locations of wiring harnesses.

PART 28-02 Positive Engagement Starter

This Information Applies To All Truck Gasoline Engines Except Super Duty

DESCRIPTION AND OPERATION

POSITIVE ENGAGEMENT STARTER

The starting system includes the starter motor with an integral positive-engagement drive, the battery, a remote control starter switch (part of the ignition switch), the neutral-start switch (used with automatic transmissions), the starter relay, and heavy circuit wiring.

Turning the ignition key to the START position actuates the starter relay through the starter control circuit. The starter relay then connects the battery to the starter.

Vehicles equipped with an automatic transmission have a neutral-start switch in the starter control circuit. This prevents operation of the starter on vehicles with an automatic transmission if the selector lever is not in the N (neutral) or P (park) position.

When the starter is not in use, one of the field coils is connected directly to ground through a set of contacts (Fig. 1). When the starter is first connected to the battery, a large current flows through the grounded field coil, actuating a movable pole shoe. The pole shoe is attached to the starter drive plunger lever and thus the drive is forced into engagement with the flywheel.

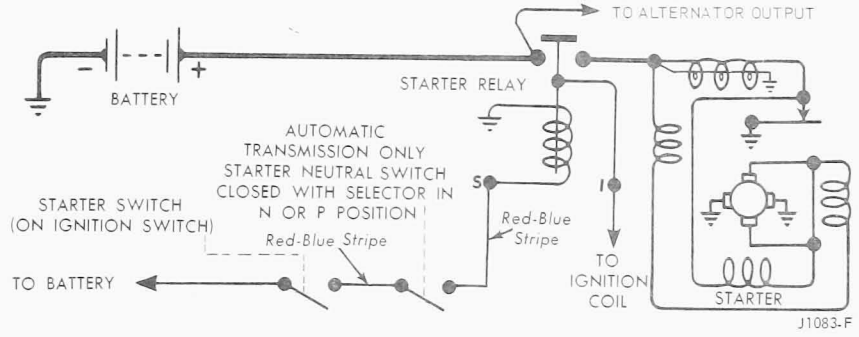

FIG. 1 Starting Circuit

When the movable pole shoe is fully seated, it opens the field coil grounding contacts and the starter is then in normal operation. Normal field current is used to maintain the movable pole shoe in the fully seated position during the time that the starter is cranking the engine.

TESTING

ROAD SERVICE

On road service calls, connect a booster battery to the system for cases of a starter that will not crank the engine or a starter that cranks the engine very slowly. If the starter does not turn the engine over, even with the booster battery attached, refer to the following tests. **Be certain that correct battery voltage polarity is observed when using a booster battery; positive to positive, and negative to negative connection of the auxiliary cables. Be sure that all lights are OFF when using a booster battery.DO NOT USE A BOOSTER BATTERY OR BATTERIES WITH A VOLTAGE GREATER THAN THE VEHICLE BATTERY VOLTAGE. TO DO SO MAY CAUSE DAMAGE TO THE STARTER.**When the engine is started with a booster battery, be certain the engine is at idle speed before disconnecting the booster battery.

ON VEHICLE TESTING

STARTER DRIVE AND STARTER TEST

Flood the warm engine by pumping the accelerator eight to ten times. Turn the ignition key to start and hold it in

the start position. The engine should fire immediately, but should not start and run. The starter should continue to crank the engine. This indicates a normal, acceptable starter drive. If the engine stops turning and the starter spins at high speed, the drive is not operating properly and should be replaced. Whenever possible, remove the plunger cover to observe if the plunger pole is operating while the starter is on the vehicle. **Do not damage the exposed switch during starter removal or installation.**

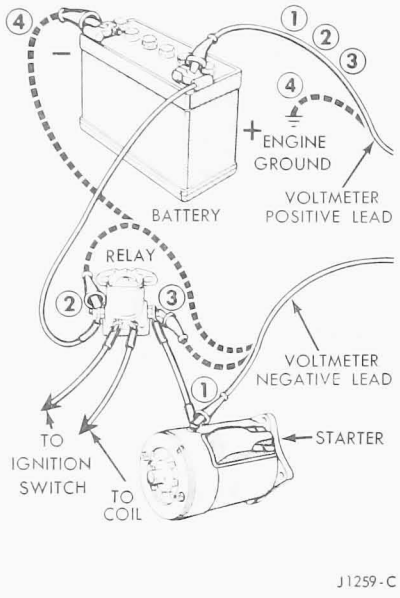

FIG. 2 Starter Cranking Circuit Test

ALTERNATE STARTER DRIVE TEST

1. Pull the push-on connector from the ignition coil primary terminal. Place the connector loosely on the coil terminal.
2. Connect a remote control starter switch to the starter relay.
3. Turn the ignition switch key to the ON position and depress the remote control starter switch. As soon as the engine begins to run, pull the push-on connector from the coil terminal while holding the remote control switch in the **start** position. Pulling the wire off the coil **kills** the ignition, and the **dead** engine should now be cranked by the starter.
4. Observe to see if the starter begins to crank the **dead** engine and if it continues to crank the engine until the remote control switch is released. If the starter does not crank the **dead** engine, the drive assembly is slipping.
5. Repeat the test at least three times in succession to detect intermittent operation.

STARTER CRANKING CIRCUIT TEST

Excessive resistance in the starter circuit can be determined from the results of this test. Make the test connections as shown in Fig. 3. Crank the engine with the ignition OFF. This is accomplished by disconnecting the grounding the high tension lead from the ignition coil and by connecting a jumper from the battery terminal of the starter relay to the S terminal of the relay.

The voltage drop in the circuit will be indicated by the voltmeter (0 to 2 volt range). Maximum allowable voltage drop should be:

1. With the voltmeter negative lead connected to the starter terminal and the positive lead connected to the battery positive terminal (Fig. 2, connection (1)) ...0.5 volt.
2. With the voltmeter negative lead connected to the battery terminal of the starter relay and the positive lead connected to the positive terminal of the battery (Fig. 2, connection (2))...0.1 volt.
3. With the voltmeter negative lead connected to the starter terminal of the starter relay and the positive lead connected to the positive terminal of the battery (Fig. 2, connection (3))...0.3 volt.
4. With the voltmeter negative lead connected to the negative terminal of the battery and the positive lead connected to the engine ground (Fig. 2, connection (4))...0.1 volt.

STARTER LOAD TEST

Connect the test equipment as shown in Fig. 3. Be sure that no current

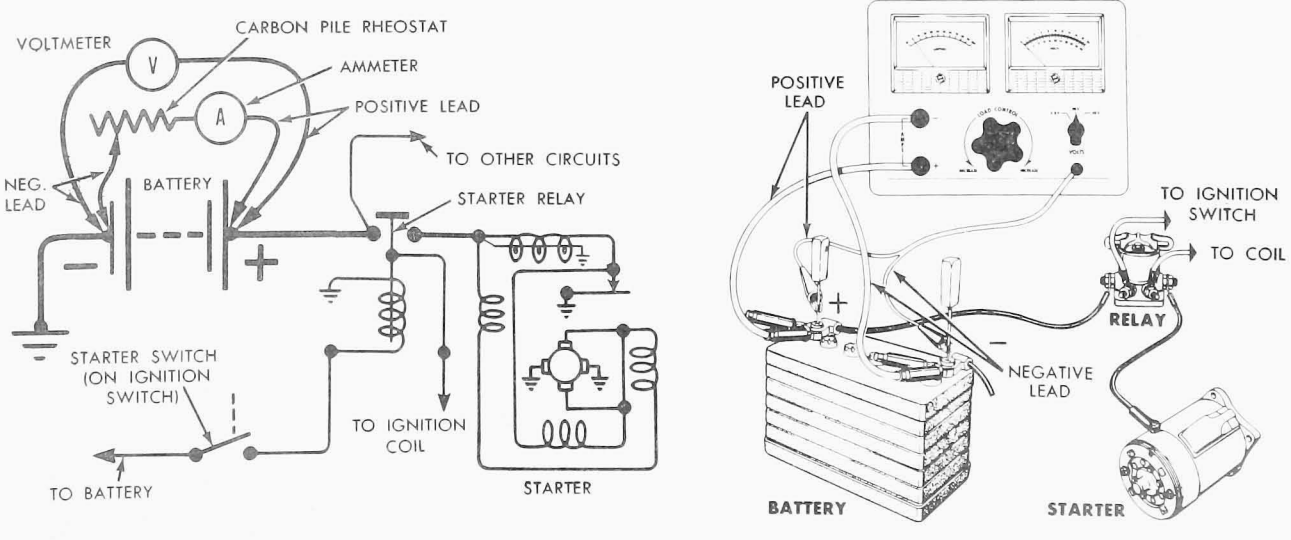

FIG. 3 Starter Load Test

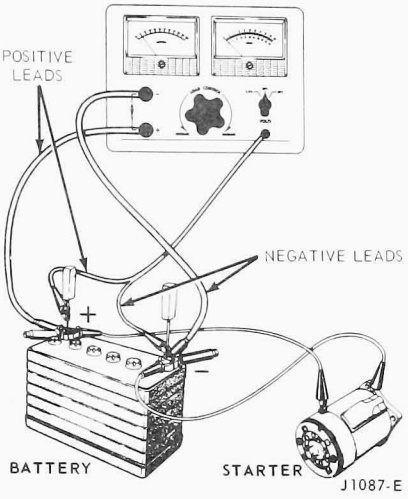

FIG. 4 Starter No-Load Test on Test Bench

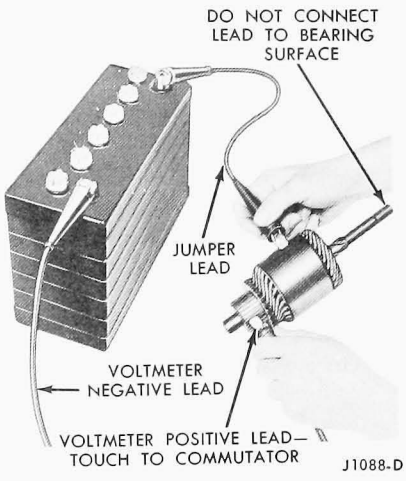

FIG. 5 Armature Grounded Circuit Test

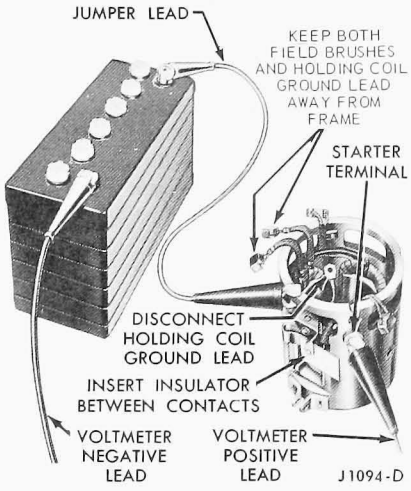

FIG. 6 Field Grounded Circuit Test

is flowing through the ammeter and heavy-duty carbon pile rheostat portion of the circuit (rheostat at maximum counterclockwise position).

Crank the engine with the ignition OFF, and determine the exact reading on the voltmeter. This test is accomplished by disconnecting and grounding the high tension lead from the ignition coil, and by connecting a jumper from the positive battery terminal to the "S" terminal of the starter relay.

Stop cranking the engine. Then reduce the resistance of the carbon pile until the voltmeter indicates the same reading as that obtained while the starter cranked the engine. The ammeter will indicate the starter current draw under load.

BENCH TESTS

STARTER NO-LOAD TEST

The starter no-load test will uncover open or shorted windings, rubbing armature, and bent armature shaft. The starter can be tested, at no-load, on the test bench only.

Make the test connections as shown in Fig. 4. The starter will run at no-load. Be sure that no current is flowing through the ammeter (rheostat at maximum counterclockwise position). Determine the exact reading on the voltmeter.

Disconnect the starter from the battery. Then, reduce the resistance of the rheostat until the voltmeter indicates the same reading as that obtained while the starter was running. The ammeter will indicate the starter no-load current draw.

ARMATURE OPEN CIRCUIT TEST—ON TEST BENCH

An open circuit armature may sometimes be detected by examining the commutator for evidence of burning. A spot burned on the commutator is caused by an arc formed every time the commutator segment, connected to the open circuit winding, passes under a brush.

ARMATURE AND FIELD GROUNDED CIRCUIT TEST—ON TEST BENCH

This test will determine if the winding insulation has been damaged, permitting a conductor to touch the frame or armature core.

To determine if the armature windings are grounded, make the connections as shown in Fig. 5. If the voltmeter indicates any voltage, the windings are grounded.

Grounded field windings can be detected by making the connections as shown in Fig. 6. If the voltmeter indicates any voltage, the field windings are grounded.

REMOVAL AND INSTALLATION

POSITIVE ENGAGEMENT STARTER

1. Raise the vehicle on a hoist (light vehicles).
2. Disconnect the starter cable at the starter terminal.
3. Remove the starter mounting bolts. Remove the starter assembly (Fig. 7).
4. Position the starter assembly to the flywheel housing, and start the mounting bolts.
5. Snug all bolts while holding the starter squarely against its mounting surface and fully inserted into the pilot hole. Torque the bolts to specification.
6. Connect the starter cable.
7. Lower the vehicle. Check the operation of the starter.

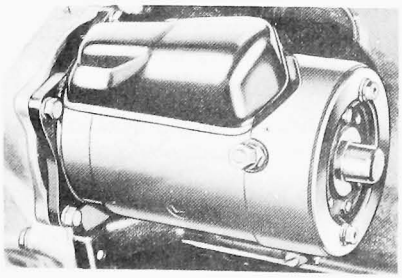

FIG. 7 Starter Mounting

OVERHAUL

POSITIVE ENGAGEMENT STARTER

Use the following procedures when it becomes necessary to completely overhaul the starter. Fig. 8 illustrates a partially disassembled starter.

Disassembly

1. Loosen the brush cover band retaining screw and remove the brush cover band and the starter drive plunger lever cover. Observe the lead positions for assembly and then remove the commutator brushes from the brush holders.
2. Remove the through bolts, starter drive end housing, and the starter drive plunger lever return spring.
3. Remove the pivot pin retaining the starter gear plunger lever and remove the lever and the armature.
4. Remove the stop ring retainer. Remove and discard the stop ring retaining the starter drive gear to the end of the armature shaft, and remove the starter drive gear assembly.
5. Remove the brush end plate.
6. Remove the two screws retaining the ground brushes to the frame.
7. On the field coil that operates the starter drive gear actuating lever, bend the tab up on the field coil retaining sleeve and remove the sleeve.
8. Remove the three coil-retaining screws, using Tool 10044-A and an arbor press (Fig. 9). The arbor press prevents the wrench from slipping out of the screw. Unsolder the field coil leads from the terminal screw, and remove the pole shoes and coils from the frame. Use a 300-watt solder iron.
9. Cut (or unsolder) the insulated brush leads from the field coils, as close to the field connection point as possible.
10. Remove the starter terminal nut, washer, insulator and terminal from the starter frame. Remove any excess solder from the terminal slot.

Cleaning and Inspection

1. Use a brush or air to clean the field coils, armature, commutator, armature shaft, brush end plate, and drive end housing. Wash all other parts in solvent and dry the parts.
2. Inspect the armature windings for broken or burned insulation and unsoldered connections.
3. Check the armature for open circuits and grounds.

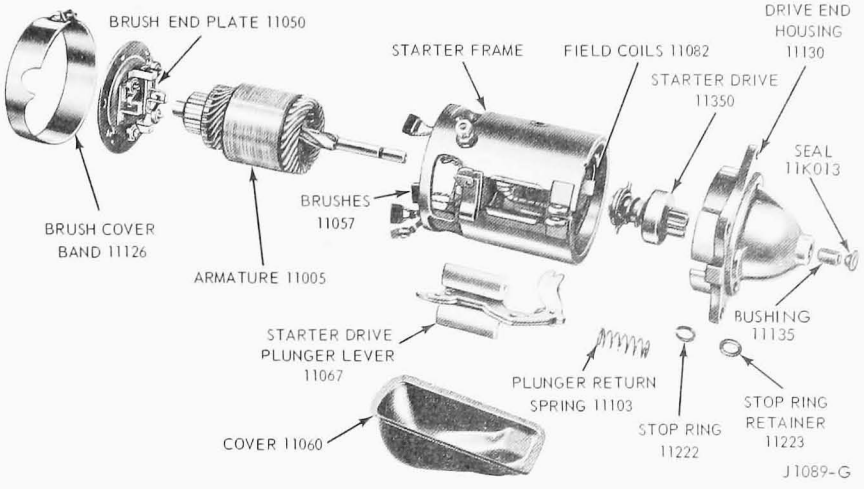

FIG. 8 Starter Disassembled

4. Check the commutator for runout (Fig. 10). Inspect the armature shaft and the two bearings for scoring and excessive wear. If the commutator is rough, or more than 0.005 inch out-of-round, turn it down.
5. Check the brush holders for broken springs and the insulated brush holders for shorts to ground. Tighten any rivets that may be loose. Replace the brushes if worn to 1/4 inch in length.
6. Check the brush spring tension. Replace the springs if the tension is not within specified limits (40 ounces minimum).
7. Inspect the field coils for burned or broken insulation and continuity. Check the field brush connections and lead insulation. A brush kit and a contact kit are available. All other assemblies are to be replaced rather than repaired.
8. Examine the wear pattern on the starter drive teeth. The pinion teeth must penetrate to a depth greater than 1/2 the ring gear tooth depth (Fig. 11), to eliminate premature ring gear and starter drive failure.
9. Replace starter drives and ring gears with milled, pitted or broken teeth or that show evidence of inadequate engagement (Fig. 11).

Assembly

1. Install the starter terminal, insulator, washers, and retaining nut in the frame (Fig. 12). Be sure to position the slot in the screw perpendicular to the frame end surface.

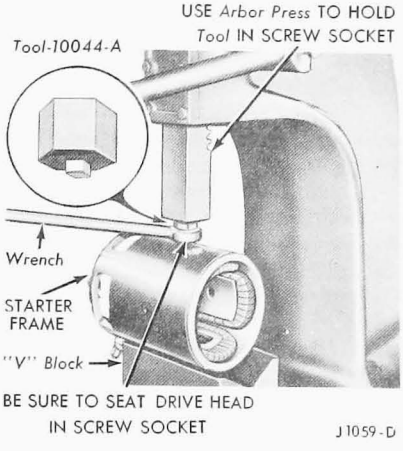

FIG. 9 Pole Shoe Screw Removal

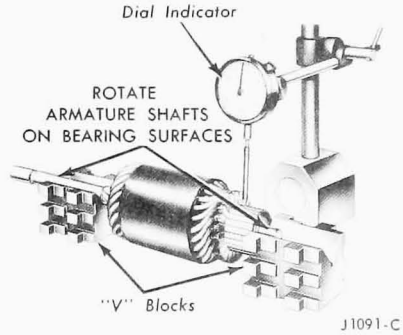

FIG. 10 Commutator Runout Check

2. Position the coils and pole pieces, with the coil leads in the terminal screw slot, and then install the retaining screws (Fig. 8). As the pole shoe screws are tightened, strike the

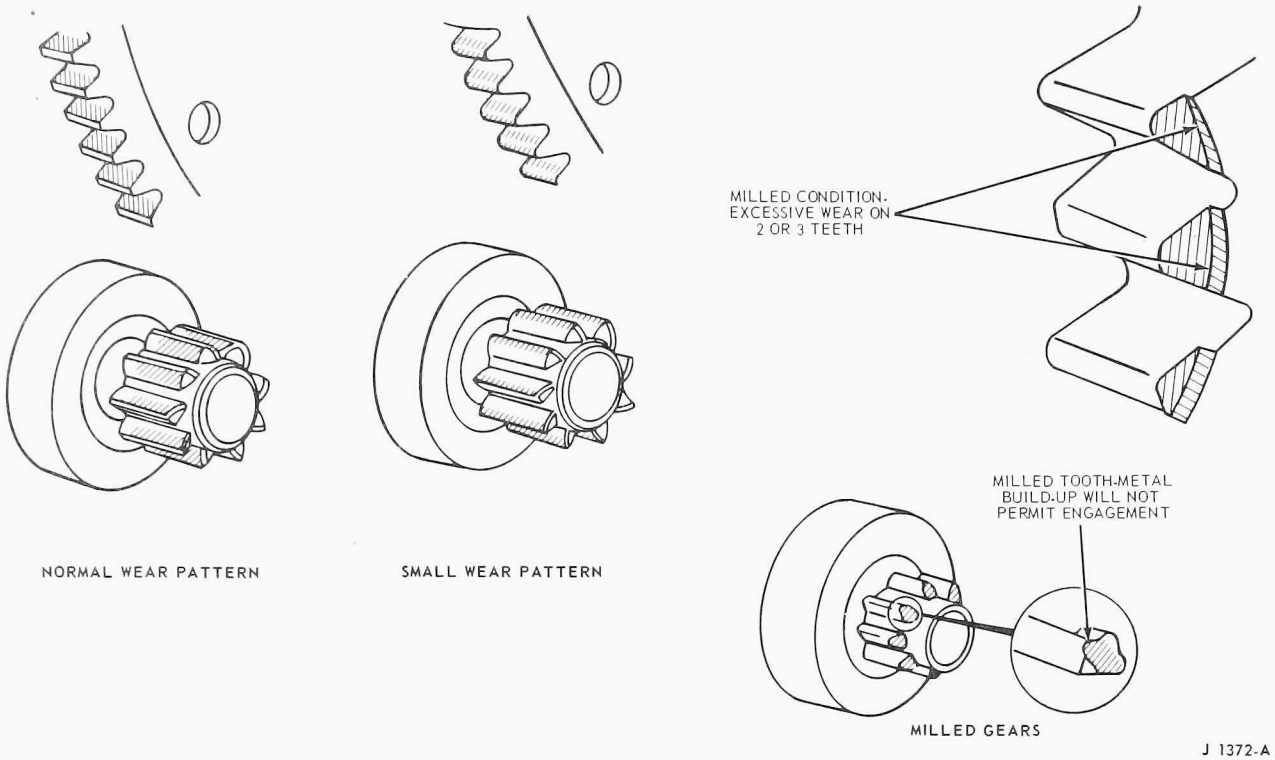

FIG. 11 Pinion and Ring Gear Wear Patterns

frame several sharp blows with a soft-faced hammer to seat and align the pole shoes, then stake the screws.

3. Install the solenoid coil and retainer and bend the tabs to retain the coils to the frame.
4. Solder the field coils and solenoid wire to the starter terminal using rosin core solder. Use a 300-watt iron.
5. Check for continuity and grounds in the assembled coils.
6. Position the new insulated field brushes lead on the field coil terminal. Install the clip provided with the brushes to hold the brush lead to the terminal. Solder the lead, clip, and terminal together, using rosin core solder (Fig. 12). Use a 300-watt iron.
7. Position the solenoid coil ground terminal over the nearest ground screw hole.
8. Position the ground brushes to the starter frame and install the retaining screws (Fig. 12).
9. Position the starter brush end plate to the frame with the end plate boss in the frame slot.
10. Apply a thin coating of Lubriplate 777 on the armature shaft splines. Install the starter motor drive gear assembly to the armature shaft and install a new retaining stop ring. Install a new stop retainer.
11. Position the fiber thrust washer on the commutator end of the armature shaft and position the armature in the starter frame.
12. Partially fill the drive end housing bearing bore with grease (approximately 1/4 full). Position the starter drive gear plunger lever to the frame and starter drive assembly, and install the pivot pin.
13. Position the starter drive plunger lever return spring and the drive end housing to the frame and install and tighten the through bolts to specification (55-75 inch pounds). **Do not pinch the brush leads between the brush plate and the frame.** Be sure that the stop ring retainer is seated properly in the drive housing.
14. Install the brushes in the brush holders. **Be sure to center the brush springs on the brushes.**
15. Position the drive gear plunger lever cover on the starter and install the brush cover band with a gasket. Tighten the band retaining screw.
16. Check the starter no-load current draw.

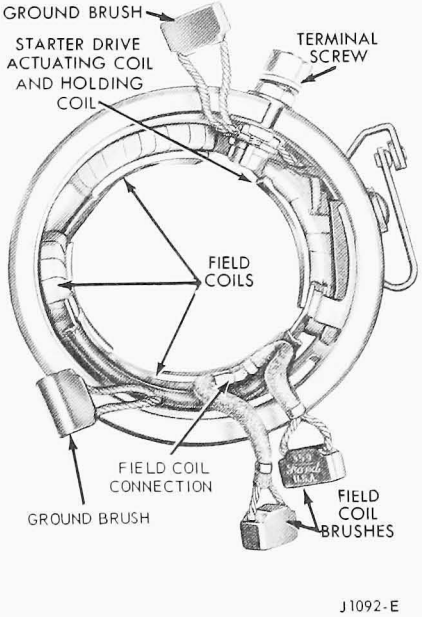

FIG. 12 Field Coil Assembly

STARTER DRIVE REPLACEMENT

1. Loosen and remove the brush cover band and the starter drive plunger lever cover (Fig. 8).
2. Loosen the through bolts enough to allow removal of the drive end housing and the starter drive plunger lever return spring.

3. Remove the pivot pin retaining the starter drive plunger lever and remove the lever.
4. Remove the drive gear stop ring retainer and stop ring from the end of the armature shaft and remove the drive gear assembly.
5. Apply a thin coating of Lubriplate 777 on the armature shaft splines. Install the drive gear assembly on the armature shaft and install a new stop ring.
6. Position the starter gear plunger lever on the starter frame and install the pivot pin. **Be sure that the plunger lever properly engages the starter drive assembly.**
7. Install a new stop-ring retainer. Partially fill the drive end housing bearing bore with grease (approximately 1/4 full). Position the starter drive plunger lever return spring and drive end housing to the starter frame, and then tighten the through bolts to specifications (55-75 inch pounds).
8. Position the starter drive plunger lever cover and the brush cover band, with its gasket, on the starter. Tighten the brush cover band retaining screw.

BRUSH REPLACEMENT

Replace the starter brushes when they are worn to 1/4 inch. Always install a complete set of new brushes.

1. Loosen and remove the brush cover band, gasket, and starter drive plunger lever cover. Remove the brushes from their holders.
2. Remove the two through bolts from the starter frame.
3. Remove the drive end housing, and the plunger lever return spring.
4. Remove the starter drive plunger lever pivot pin and lever, and remove the armature.
5. Remove the brush end plate.
6. Remove the ground brush retaining screws from the frame and remove the brushes.
7. Cut the insulated brush leads from the field coils, as close to the field connection point as possible.
8. Clean and inspect the starter motor.
9. Replace the brush end plate if the insulator between the field brush holder and the end plate is cracked or broken.
10. Position the new insulated field brushes lead on the field coil connection. Position and crimp the clip provided with the brushes to hold the brush lead to the connection. Solder the lead, clip, and connection together, using rosin core solder (Fig. 12). Use a 300-watt iron.
11. Install the ground brush leads to the frame with the retaining screws.
12. Clean the commutator with 00 or 000 sandpaper.
13. Position the brush end plate to the starter frame, with the end plate boss in the frame slot.
14. Install the armature in the starter frame.
15. Install the starter drive gear plunger lever to the frame and starter drive assembly, and install the pivot pin.
16. Partially fill the drive end housing bearing bore with grease (approximately 1/4 full). Position the return spring on the plunger lever, and the drive end housing to the starter frame. Install the through bolts and tighten to specified torque (55-75 inch pounds). Be sure that the stop ring retainer is seated properly in the drive end housing.
17. Install the commutator brushes in the brush holders. Center the brush springs on the brushes.
18. Position the plunger lever cover and the brush cover band, with its gasket on the starter. Tighten the band retaining screw.
19. Connect the starter to a battery to check its operation.

ARMATURE REPLACEMENT

1. Loosen the brush cover band retaining screw and remove the brush cover band, gasket, and the plunger lever cover. Remove the brushes from their holders.
2. Remove the through bolts, the drive end housing, and the drive plunger lever return spring.
3. Remove the pivot pin retaining the starter gear plunger lever, and remove the lever.
4. Remove the armature. If the starter drive gear assembly is being reused, remove the stop ring retainer and the stop ring from the end of the armature shaft, and remove the drive.
5. Place the drive gear assembly on the new armature with a new stop ring.
6. Install the armature in the starter frame.
7. Position the drive gear plunger lever to the frame and drive gear assembly and install the pivot pin.
8. Partially fill the drive end housing bearing bore with grease (approximately 1/4 full). Position the drive plunger lever return spring, the drive end housing and the front end plate to the starter frame; then, install and tighten the through bolts to specification. Be sure that the stop ring retainer is seated properly in the drive housing.
9. Place the brushes in their holders, and center the brush springs on the brushes.
10. Position the plunger lever cover and the brush cover band, with its gasket, and then tighten the retaining screw.
11. Connect the starter to a battery to check its operation.

STARTER TERMINAL

Removal

1. Loosen the brush cover band retaining screw and remove the brush cover band and the starter drive plunger lever cover. Observe the lead positions for assembly and then remove the commutator brushes from the brush holders.
2. Remove the through bolts, starter drive end housing, starter drive plunger lever return spring, and the brush end plate.
3. Remove the pivot pin retaining the starter gear plunger lever and remove the lever and the armature assembly.
4. Unsolder the field coil and solenoid wire leads from the terminal screw. Use a 300-watt soldering iron.

Remove the starter terminal nut, washer, insulator and terminal from the starter frame.

Installation

1. Install the new starter terminal, insulator, washers, and retaining nut in the frame (Fig. 8). Be sure to position the slot in the screw perpendicular to the frame end surface.
2. Solder the field coils and solenoid wire to the starter terminal using rosin core solder. Use a 300-watt iron.
3. Check for continuity and grounds in the assembled coils.
4. Position the starter brush end plate to the frame with the end plate boss in the frame slot.
5. Position the armature in the starter frame.
6. Position the starter drive gear plunger lever to the frame and starter drive assembly, and install the pivot pin.
7. Partially fill the drive end housing bearing bore with grease (approximately 1/4 full). Position the starter drive plunger lever return spring and the drive end housing to the frame and install and tighten the through bolts to specification (55-75 in-lbs). **Do not pinch the brush leads between the brush plate and the frame.** Be sure that the stop ring retainer is seated properly in the drive housing.

8. Install the brushes in the brush holders. **Be sure to center the brush springs on the brushes.**
9. Position the drive gear plunger lever cover on the starter and install the brush cover band with a gasket. Tighten the band retaining screw.
10. Check the starter no-load current draw.

Cleaning and Inspection	10-05		
Starter Drive Replacement	10-06		

DESCRIPTION AND OPERATION

The Delco starter is a 12-volt unit that has the solenoid mounted on the starter housing (Fig. 1). The solenoid is energized when the starter relay contacts are closed. This action engages the starter drive with the flywheel ring gear, starting the engine. An overrunning clutch in the drive protects the starter from excessive speed when the engine starts. The starter current flows through the solenoid energizing coil until the solenoid plunger is at the end of its travel. The plunger then closes a set of contacts that by-pass the energizing coil, letting the holding coil keep the starter drive engaged. A Typical installation of the Delco 12-volt starting system is shown in Fig. 3.

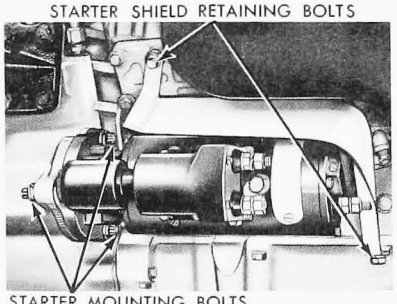

FIG. 1 Delco Starter Mounting

TESTING

ROAD SERVICE

On road service calls, connect a booster battery to the system for cases of a starter that will not crank the engine or a starter that cranks the engine very slowly. If the starter turns the engine over, but the engine still will not start, even with the booster battery attached, refer to the following tests. **Be certain that correct battery polarity is observed when using a booster battery; positive to positive, and negative to negative connection of the auxiliary cables.**

ON VEHICLE TESTING

STARTER CRANKING CIRCUIT TEST

Excessive resistance in the starter circuit can be determined from the results of this test. Make the test connections as shown in Fig. 2 on each set of batteries. Crank the engine with the ignition OFF. This is accomplished by disconnecting and grounding the high tension lead from the ignition coil and by connecting a jumper from the battery terminal of the starter solenoid to the energizing terminal (black wire), of the starter solenoid.

The voltage drop in the circuit will be indicated by the voltmeter (0 to 2 volt range). Maximum allowable voltage drop for each set of batteries should be:

1. With the voltmeter negative lead connected to the starter terminal and the positive lead connected to the battery positive terminal (Fig. 2, connection (1))...0.5 volt.
2. With the voltmeter negative lead connected to the battery terminal of the starter relay and the positive lead

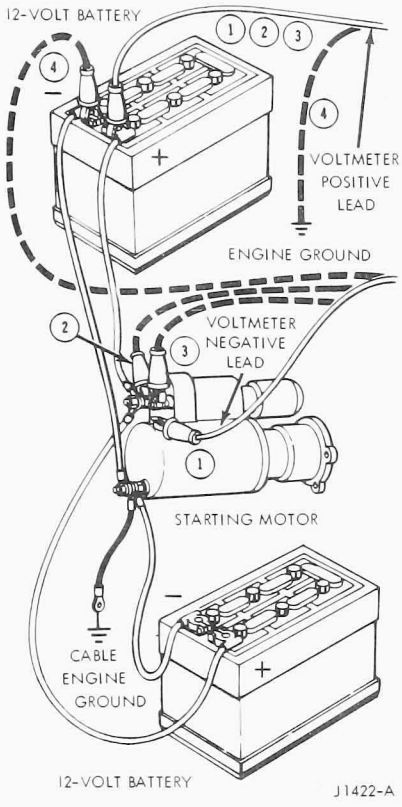

FIG. 2 Starter Cranking Circuit Test

connected to the positive terminal of the battery (Fig. 2, connection (2))...0.1 volt.

3. With the voltmeter negative lead connected to the starter terminal of the starter relay and the positive lead connected to the positive terminal of the battery (Fig. 2, connection (3))...0.3 volt.
4. With the voltmeter negative lead connected to the negative terminal of the battery and the positive lead connected to the engine ground (Fig. 2, connection (4))...0.1 volt.

STARTER LOAD AND NO-LOAD TESTS

Follow the procedures under these headings given in Part 28-02, Testing.

REMOVAL AND INSTALLATION

STARTER

Removal

1. Open the battery box and disconnect the battery cables.
2. Remove one bolt and lock washer securing the battery cable retainer to the right rear cylinder head cover.
3. Remove the starter upper mounting bolt (Fig. 1).
4. Remove the clamps securing the resonator inlet pipes to the exhaust manifolds, and position the inlet pipes out of the way.
5. Remove the starter shield retaining bolts (Fig. 1).
6. Disconnect the starter and starter solenoid wires. Tag the wires to facilitate connection at the proper terminals during starter installation.
7. Remove the two remaining starter mounting bolts and lock washers. Remove the starter.

Installation

1. Position the starter on the engine, and install three bolts and lock washers. Tighten securely.
2. Connect the solenoid wire to the starter terminal (Fig. 3).
3. Install the starter shield on the engine with two retaining bolts.
4. Connect the remaining starter wires to the starter terminals.
5. Connect the resonator inlet pipes to the exhaust manifolds, and secure with clamps.
6. Connect the battery cables and close the battery box. Check the operation of the starter.

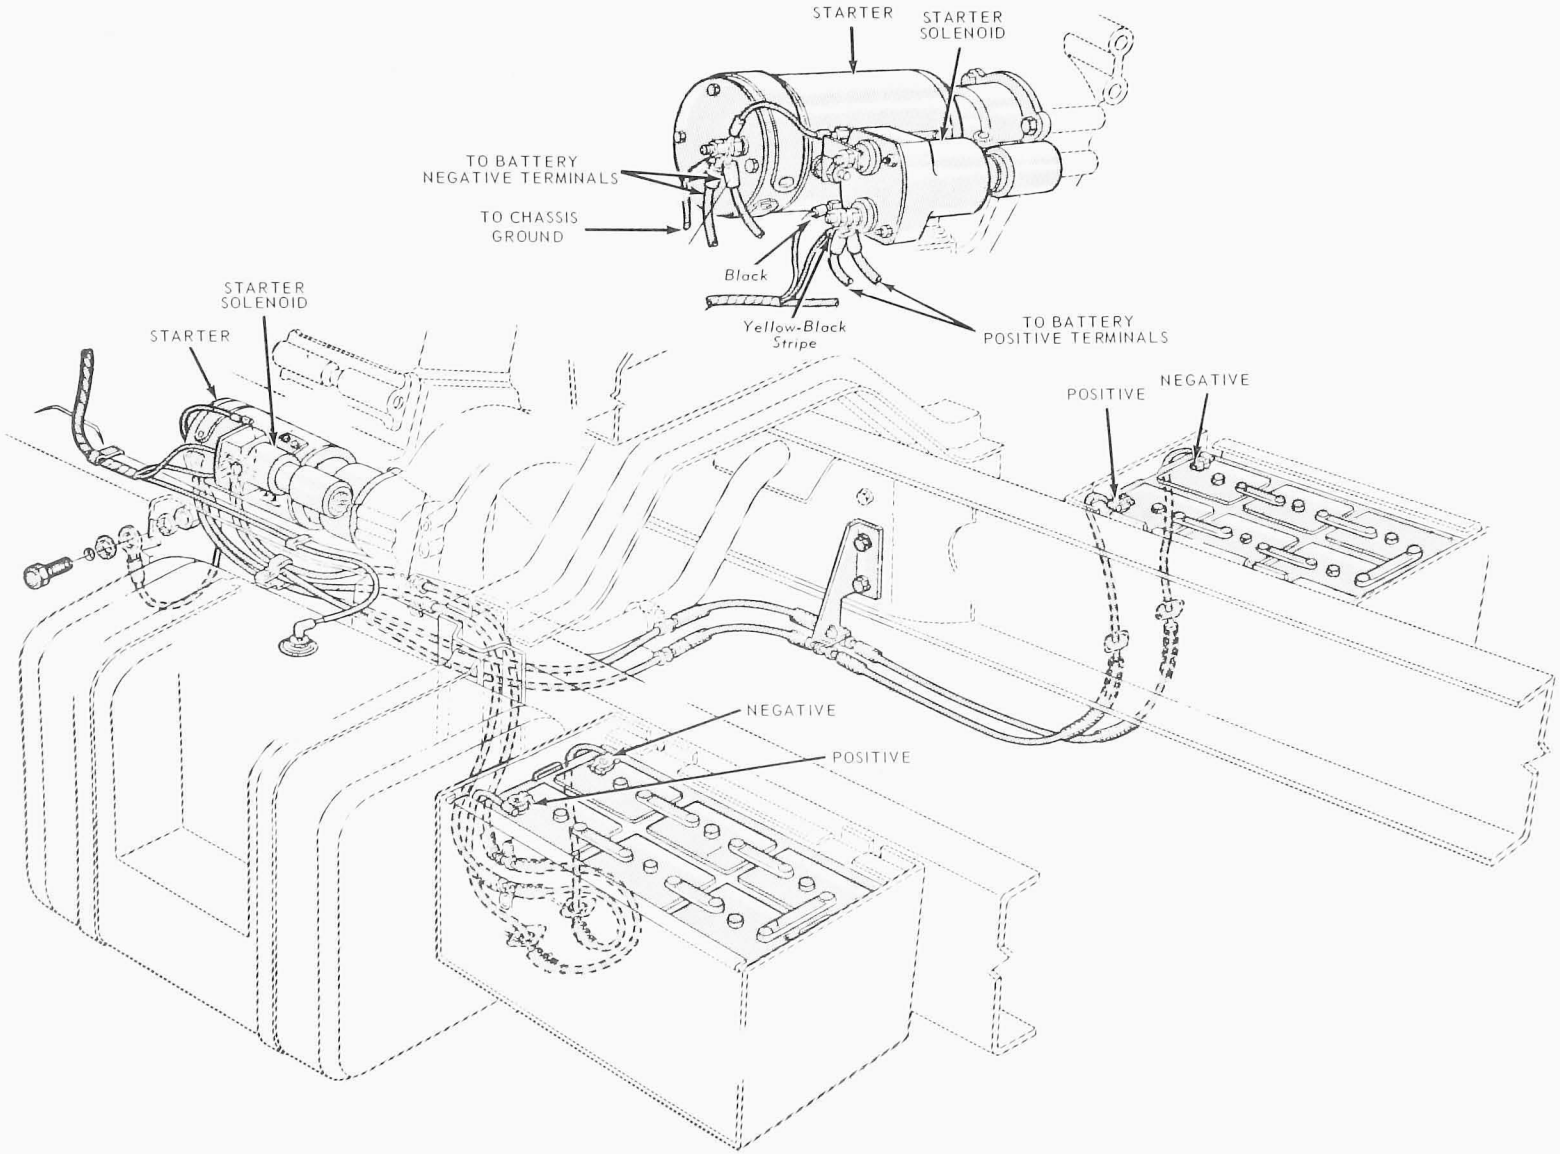

FIG. 3 12-Volt Delco Starter Cable Connections

OVERHAUL

12-VOLT STARTER

DISASSEMBLY

1. Thoroughly clean the outside of the starter.
2. Remove the four screws securing the inspection plates and gaskets to the starter frame.
3. Remove the four bolts securing the brush end plate, and rotate the end plate to expose two screws securing the field coil leads to the brush end plate. Remove the screws.
4. Remove the brush end plate (Fig. 4). If the brushes are to be replaced, see Brush Removal and Installation.
5. Remove the large screw plug from the starter yoke housing.
6. Remove the six Allen-head screws securing the starter drive end plate (Fig. 4). Remove the end plate.
7. Remove the starter yoke adjusting nut.
8. Remove the five bolts securing the starter yoke housing, and remove the housing.
9. Remove the C-clip from the yoke center pin and drive the pin out.
10. Remove the starter clutch and drive assembly, and the armature from the starter frame.
11. To remove the solenoid assembly, proceed as follows: Remove the four screws attaching the solenoid to the starter frame. Remove the copper strap from the motor side of the solenoid-to-starter terminal. Remove the solenoid from the starter.
12. Disconnect the field coil connector from the solenoid motor terminal, and remove the lead from the solenoid ground terminal.
13. Remove the field coils from the starter frame by using a pole shoe screwdriver and arbor press.
14. To disassemble the solenoid, proceed as follows: Remove all wires and screws from the solenoid terminal end. Remove the four self-

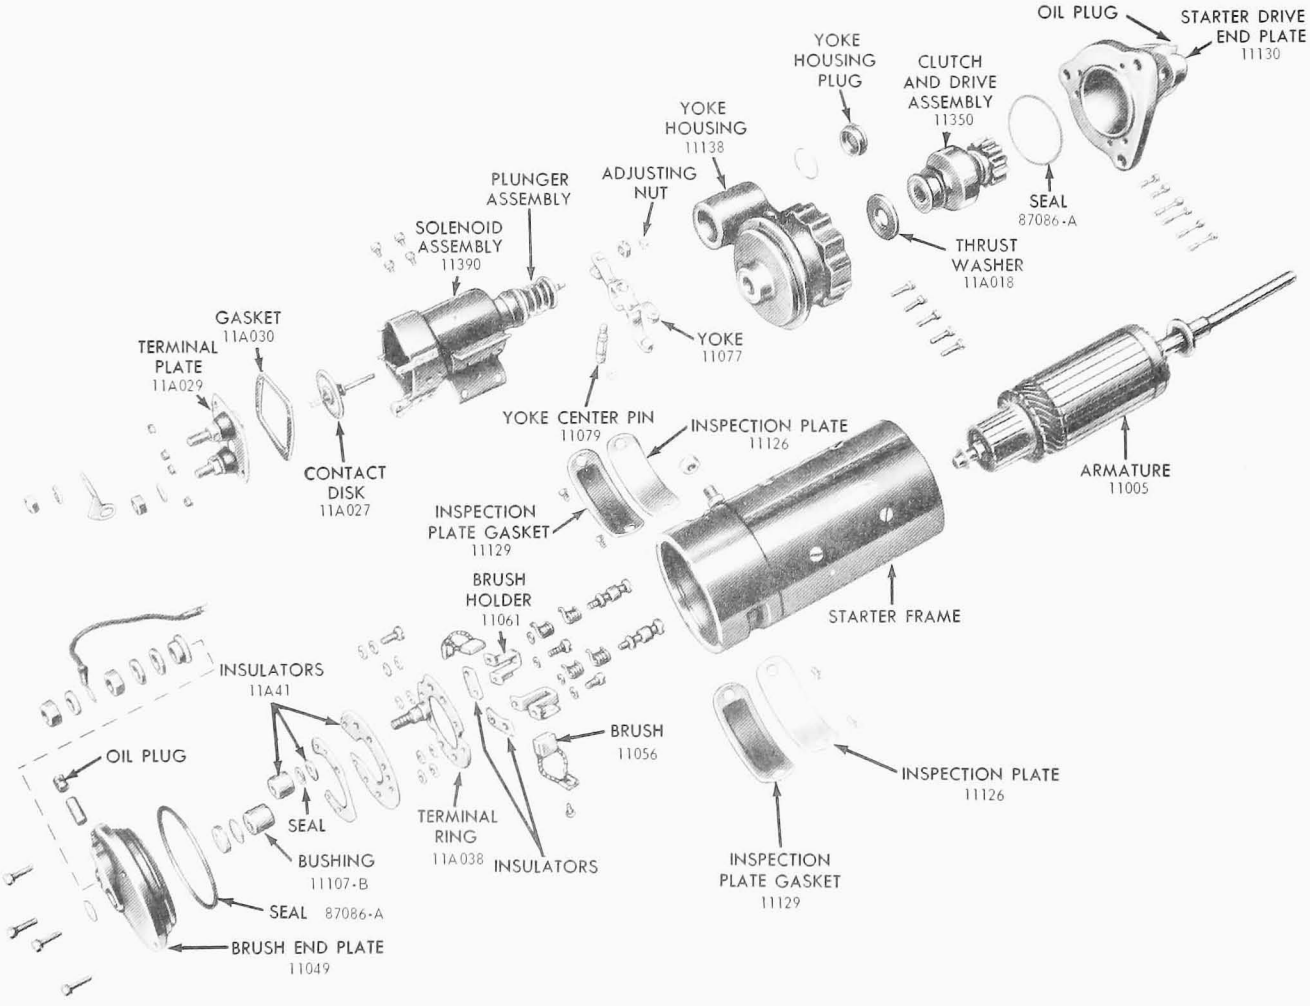

FIG. 4. Disassembled 12-Volt Delco Starter

locking nuts and nylon washers retaining the solenoid end plate; pull the plate away from the solenoid and remove one screw securing the internal wire. Remove the contact disc, plunger, and spring. To replace the contact bolts, remove the large nuts, washers and insulated washers, and remove the contact bolts. Replace the cork gasket, if necessary, and install the bolts, washers and nuts.

15. To disassemble the brush end plate, remove the three screws attaching the brush holder to the end plate. Remove the nut and lock washer on the terminal bolt and remove two fiber insulators, the rubber O-ring, and the fiber sleeve.

Assembly

1. If the starter solenoid assembly was disassembled, install the plunger and spring, and position the contact disk. Position the solenoid end plate, and install the internal wire. Install the four self-locking nuts and nylon washers which retain the end plate. Install the wires and screws to the outside terminals.
2. Assemble the field coils and pole shoes to the starter frame. Position the field terminal leads in the open windows of the frame.
3. Assemble the armature and brush end plate to the starter frame. Connect the two field leads to the brush brackets. Tap the end plate lightly after alignment, and install the four retaining bolts.
4. Using a drift, drop the brushes into position.
5. Lubricate the drive end bushing and splines of the armature shaft with SAE 10W oil. **Do not use heavier oil.**
6. Position the starter clutch and drive assembly.
7. Position the starter yoke, and install the center pin and C-clip.
8. Position the starter yoke housing and secure it in place with five bolts.
9. Position the drive end plate and secure it in place with six Allen-head screws. The two short screws are installed on the solenoid side of the starter.
10. Install the starter solenoid on the starter with four screws. Install the copper ground strap.
11. Install the yoke adjusting nut, and adjust the drive gear end play.
12. Install the large screw plug in the yoke housing.
13. Position the inspection covers and gaskets, and secure with four screws.

CLEANING AND INSPECTION

12-VOLT STARTER

1. Wipe the field coils, armature, commutator and armature shaft with a clean cloth. Wash the springs, shims, thrust washer, trip collar, locking collar, pinion assembly, pinion spring cover, and brush end plate assembly in solvent and dry the parts.
2. Inspect the armature for broken or burned insulation and unsoldered connections. Inspect the commutator surface for grooves, and check for runout.

If the surface of the commutator is rough or more than 0.002 inch out of round, turn it down. Do not undercut the mica.

3. Check the armature windings with a growler tester.
4. Inspect the ball recesses in the armature shaft for burrs caused by the locking balls. Use a fine oil stone to remove the burrs. Inspect the shaft helices for excessive wear.
5. With the starter disassembled, check the field windings with a growler light for shorts to the housing or pole shoes. Connect one growler light lead to the starter housing; connect the other growler lead to each of the field coil brush leads in turn. A short circuit will light the growler light. Replace damaged coils.
6. Examine the starter bushings for excessive wear. Replace worn or badly scored bushings.

Before assembling the starter, the armature bushing in the brush end plate should be lubricated by soaking for 24 hours in oil-SAE 10W/30W or SAE 5W/20W (subzero climates). To soak the bushing, plug one end and fill the bushing with oil. A new bushing should be similarly soaked before assembly.

7. Examine the contacts on the solenoid assembly, and if necessary, clean them with very fine sandpaper or crocus cloth.

The solenoid winding can be tested for internal shorts or open circuits with an ohmmeter. Connect the instrument across the winding and note the reading. The reading should be within the limits, 0.056-0.620 ohms for 12-volt starters. A low reading will generally indicate an internal short circuit, while no reading at all indicates an open circuit.

If the solenoid contacts are badly burned, or the solenoid winding is shorted replace the solenoid assembly.

8. Inspect the pinion teeth for excessive wear or damage from improper engagement. If a new pinion is to be installed, be sure it has the same number of teeth as the replaced component. Install the new pinion on the armature shaft and check for free movement. If necessary, the pinion and armature shaft can be lightly lapped together.
9. Check the tension of the starter springs for conformance to specifications.
10. Check the brushes for free movement in the brush holders. Inspect the brushes for excessive wear. Where brush leads are insulated, be sure that the insulation is not burned or worn.

The brushes should be well seated to the commutator; that is, worn to the commutator over at least 60 percent of the brush contact area. If not, fit the brushes to the commutator with fine sandpaper until the desired seating area is obtained. Do only one brush at a time. Clean the brushes and commutator with compressed air. Be sure that no abrasive particles are embedded in the contact area of the brushes.

New brushes are not ground to fit the commutator; therefore, they must be seated as described above.

Mark each brush and brush holder with which it was seated to permit assembly in the same position.

Check the tension of each brush spring at the point of contact with the brush. Use a spring scale hooked under the brush spring lip. Brush spring tension must be within specifications.

ENGAGEMENT MECHANISM

1. Pull the pinion forward by hand approximately 1/16 inch and release it. The pinion should return to its original position.
2. Energize the solenoid with the proper voltage battery. Connect the battery between the solenoid terminal and the ground terminal; the pinion should move forward a minimum of 1/4 inch.
3. With the solenoid energized, pull the pinion forward by hand toward its stop. The ball locking mechanism should now operate, locking the pinion in the forward position.
4. Disconnect the battery at the solenoid; the pinion must return to its normal position in one sharp movement.
5. Check the recoil spring action by applying a compression spring scale to the driving end of the armature shaft. The force required before backward movement of the shaft occurs should be 30-38 pounds.

STARTER DRIVE REPLACEMENT

1. Scribe a mark on the commutator-end plate, starter frame, drive end housing and lever housing for assembly.
2. Remove the through bolts and the commutator end plate.
3. Remove the drive-end housing, lever housing, armature and solenoid plunger as a unit.
4. Completely loosen the drive-end housing to lever housing screws, and separate the lever-end housing from the drive housing, drive assembly, and armature.
5. Remove the drive assembly stop retainer from the armature shaft, and remove the drive gear and lever-housing assembly from the armature shaft.
6. Separate the drive-gear assembly from the lever housing.
7. Position and the new drive-gear assembly and engage the shift lever in the drive-assembly flange. Position the four mounting bolts into the lever housing, position the lever housing assembly on the armature shaft and install the drive assembly stop retainer on the armature shaft.
8. Position the drive-end housing on the armature shaft, align the scribe marks made during disassembly, and tighten the drive-end housing to lever housing bolts.
9. Position the armature, lever housing and drive-end housing assembly to the starter frame, engaging the brushes onto the commutator. Align the scribe marks made during disassembly.
10. Position the commutator-end plate to the frame, align the scribe marks and install the through bolts.

BRUSH REPLACEMENT

12-VOLT STARTER

1. Thoroughly clean the outside of the starter.
2. Remove the four screws securing both inspection plates and gaskets to the starter frame.
3. Remove the four bolts securing the brush end plate, and rotate the end plate to expose two screws securing the field coil leads to the brush plate. Remove the screws.
4. Remove the brush end plate.
5. Remove the starter armature. Inspect for an open or grounded circuit.
6. If the surface of the commutator is rough or more than 0.002 inch out of round, turn down the commutator. Do not undercut the mica. Polish with 00 or 000 sandpaper to remove all burrs left by the turning operation. Be sure that no copper particles remain on the insulation between the segments.
7. Remove the six screws securing the brushes in the brush holders, and remove the eight brushes.
8. Install new brushes in the brush holders. Tighten the screws securely. Be certain that the brush tension springs are functioning correctly.
9. Position the armature in the starter. Position the brush end plate on the starter, with the brushes held in a retracted position by the brush springs. Be certain that the plate is located so that the field coil lead retaining screws can be installed.
10. Install the two field coil retaining screws, and secure the field coil leads in place.
11. Install the four bolts which attach the brush end plate to the starter frame.
12. Using a drift, drop the brushes into position.
13. Install the inspection plates and gaskets with the four attaching screws.

ARMATURE

To remove the armature, disassemble the starter with the exception of the field coils and brushes. Follow the starter disassembly procedures.

CJ1465-B

PART 28-11 Prestolite Starter

This Information Applies To All Trucks with 401, 477 and 534 C.I.D. Gasoline Engines

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	11-01	SPECIFICATIONS	11-03
DISASSEMBLY AND OVERHAUL	11-03	TESTING	11-02
REMOVAL AND INSTALLATION	11-03		

DESCRIPTION AND OPERATION

PRESTOLITE STARTER

The Prestolite starter is a heavy duty unit with an armature shaft center bearing (Fig. 1). An inertia starter drive with an overrunning clutch in the drive protects the starter from excessive speed when the engine starts.

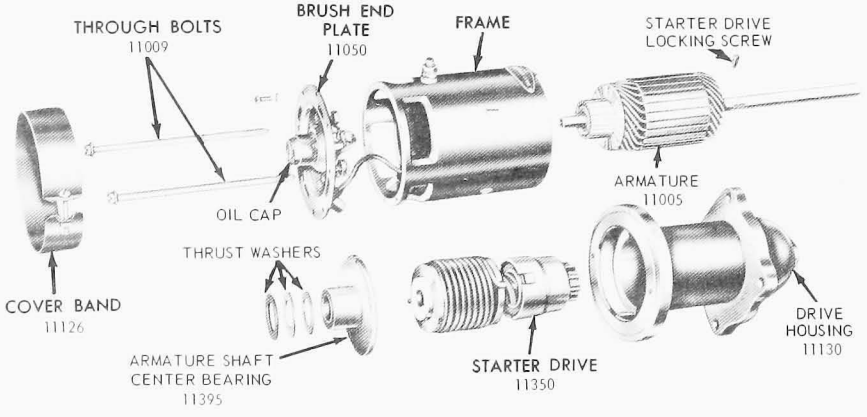

FIG. 1 Disassembled Prestolite Starter

TESTING

ROAD SERVICE

On road service calls, connect a booster battery to the system for cases of a starter that will not crank the engine or a starter that cranks the engine very slowly. If the starter cranks the engine, but the engine still will not start, even with the booster battery attached, refer to the following tests. **Be certain that correct battery polarity is observed when using a booster battery; positive to positive, and negative to negative connection of the auxiliary cables.**

STARTER CRANKING CIRCUIT TEST

Follow the procedure given in Part 28-02, Testing, Starter Cranking Circuit Test.

STARTER LOAD AND NO-LOAD TESTS

Follow the procedures under these headings given in Part 28-02, Testing.

REMOVAL AND INSTALLATION

PRESTOLITE STARTER

1. Disconnect the starter cable at the starter terminal.
2. Remove the starter mounting bolts, and remove the starter assembly. **It may be necessary to tilt the starter slightly to clear the starter drive around the flywheel.**
3. Position the starter assembly to the flywheel housing, and start the mounting bolts. On a vehicle with an automatic transmission, the transmission dipstick tube bracket is mounted under the starter side mounting bolt.
4. Snug all bolts and then tighten them to specifications (Specifications at end of this Part).
5. Connect the starter cable and check the starter operation.

OVERHAUL

PRESTOLITE STARTER

DISASSEMBLY

A disassembled view of the Prestolite starter is shown in Fig. 1.

1. Remove the cover band and remove the brushes from their holders.
2. Remove the two through bolts and the brush end plate mounting screws.
3. Remove the armature, brush end plate and drive housing from the frame. Remove the terminal from the frame.
4. Remove the four field pole shoes and slide the field coils out of the frame. If the brushes are to be replaced at this time, unsolder the old brushes from the field coils and solder new brushes in their place. The ground brushes are riveted to the brush end plate. Remove the rivets and rivet new brushes to the end plate.
5. The starter drive is held in position on the armature shaft by a locking screw and two keys. Compress the starter drive spring slightly on the armature end of the spring and remove the locking screw. Slide the starter drive off the armature shaft. No further disassembly of the drive should be made. The drive is serviced as a complete unit. **Do not lubricate the Prestolite starter drive. It should run freely after cleaning in kerosene and wiping dry.**

PARTS REPAIR OR REPLACEMENT

Nicks and scratches may be removed from the commutator by turning it down. All other serviced parts are to be replaced rather than repaired.

ASSEMBLY

1. Position the thrust washers and armature shaft center bearing on the armature shaft in the order shown in Fig. 1.
2. Slide the drive on the shaft, and install the drive locking screw.
3. Position the armature and drive in the drive housing so that the slot in the armature shaft center bearing support plate engages the pin in the drive housing, and the bearing is seated firmly in the housing.
4. Slide the field coils into the frame with the brush leads opposite the terminal hole, and install the field pole shoes. **As the pole shoe screws are tightened, strike the frame several sharp blows with a soft-faced hammer to seat and align the pole shoes. Install the terminal.**
5. Attach the brush end plate to the frame with the six screws. Position the armature and drive housing into the frame with the frame dowel engaging the hole in the drive housing, and install the through bolts.
6. Install the brushes in their holders making certain that the brush springs are centered on the brushes and that the insulated brush leads are clear of the armature.
7. Install the cover band, oil felt and oil cap. Put a few drops of engine oil in the oil cap opening.

FOREWORD

This manual is divided into five volumes: 1 – Chassis, 2 – Engine, 3 – and 4 – Electrical and Body, 5 – Maintenance and Lubrication. These volumes should provide Service Technicians with complete information covering normal service repairs on all 1973 model trucks built by the Ford Companies in the U. S. and Canada. As changes in the product occur, this information will be updated by Technical Service Bulletins. When issued, T.S.B. information always supersedes the information in the manual.

Information in each volume is grouped by system or component plus "General Service" part which contains information common to several similar components.

The table of contents on the first page of each volume indicates the general content of the book and provides a handy tab locator to make it easy to find the first page of each "Group." That page will contain an index to "Parts" and the first page of each "Part" contains a detailed index which gives page location for each service operation covered. Page numbers are consecutive in each "Part."

To make reference easier, information has been broken down into smaller units so that essentially there is now one "Part" for each component or system. Group numbers indicate the volume in which the group may be found.

Example: 11 – 02 – 21

Volume 1 – Group 11 – Part 02 – Page 21

Identification Codes

GROUP 30

PART 30-03 Truck Identification Codes

The Vehicle Certification Label (V.C. Label) is attached to the rear face of the driver's door. The upper half of the label contains the name of the manufacturer, the month and year of manufacture and the certification statement. The V.C. Label also contains the Vehicle Identification Number.

The remaining information codes on the V.C. Label are the same as the Truck Rating Plate Codes (Fig. 1). Vehicle codes shown on the Truck Rating Plate are explained in the following paragraphs.

RATING PLATE

Figure 1 illustrates a typical truck Rating Plate. On light and medium cowl and windshield vehicles, the Rating Plate is mounted on the right side of the cowl top panel under the hood. On stripped Parcel Delivery vehicles, the rating plate is placed in an envelope and included in the Boxed Items parts. On Bronco models, the plate is mounted on the inside panel of the glove compartment door. On all other vehicles, the Rating Plate is mounted on the rear face of the left front door.

VEHICLE IDENTIFICATION NUMBER

The identification number is the first line of numbers and letters appearing on the Rating Plate (Fig. 1). The first letter and two numbers indicate the truck model and series (the letter prefix identifies the type of body or cab and the numbers are the first two numbers of a truck series). The letter following the truck series code designates the engine identification code. The letter following the engine identification code indicates the assembly plant at which the vehicle was built. The remaining numbers indicate the consecutive unit number. The charts that follow list the various vehicle identification number codes.

VEHICLE DATA

The Vehicle Data appears on the Rating Plate on the two lines following the identification number. The first three digits under **W.B. designate the wheelbase in inches. The one or two letters under COLOR** identify the exterior paint color (two letters

W1017-F

designate a two-tone). The letter and three digits under **MODEL** designate the truck model within a series. The letter and numerals under **BODY** designate the interior trim and body type (the letter identifies the interior trim scheme and the numerals identify the body or cab type). The transmission installed in the vehicle is identified under **TRANS** by either a numeric or alphabetical code (if two symbols appear, the first identifies the auxiliary transmission, if so equipped, and the second symbol identifies the main transmission). A letter and a number or two numbers under **AXLE** identify the rear axle ratio (when required, a letter is also stamped behind the rear axle code to identify the front axle capacity). The maximum gross vehicle weight in pounds is stamped under**MAX. G.V.W. A two-digit number is stamped under** D.S.O. **to identify the district which ordered the vehicle. If the vehicle is built to special order (Domestic Special Order, Foreign Special Order, Limited Production Option, or other special order), the complete order number will also appear under** D.S.O. The charts that follow list the various vehicle data codes.

DESCRIPTION AND OPERATION

CHARGING SYSTEM FUSE LINK

The fuse link used on the Bronco, Econoline, Club Wagons, Parcel Delivery and light trucks, is a short length of insulated wire integral with the engine compartment wiring harness. It is several wire gages smaller than the circuit that it protects and is the color of the circuit being supplied by the fuse link. Service fuse links are green or black depending on usage. All fuse links have a flag moulded on the wire or on the terminal insulator. Color identification of the flag or connector is Red—18 ga. wire, Orange—16 ga. wire, or Green—14 ga. wire. Fig. 1 shows the fuse link installations.

The fuse link is designed to burn out, thus protecting the alternator and wiring when heavy reverse current

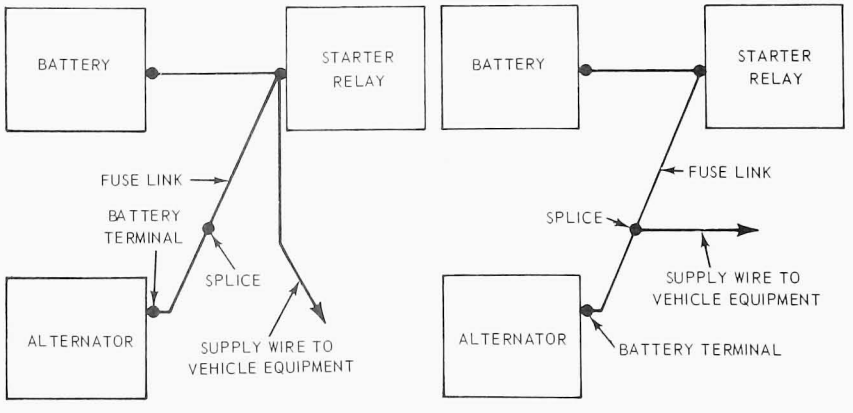

FIG. 1 Fuse Link Installations

flows, such as when a booster battery is connected incorrectly, or a short to ground occurs in the wiring harness.

A burned out link may have bare wire ends protruding from the insulation, or it may only have expanded or bubbled insulation. If it is hard to determine if the link is burned out, perform a continuity test.

TESTING

CHARGING SYSTEM

The alternator and alternator regulator are precision built units, and the equipment to make tests in the charging system must be accurate. Voltmeters must be accurate within 0.1 (one tenth) volt within the range of 12 to 16 volts and ammeters within one ampere at 30 to 90 amperes to permit correct measurement of the alternator and regulator. The meters on Rotunda equipment should be calibrated once a year and the date of calibration stamped on the meter face. It is recommended that this practice be followed by technicians with other than approved equipment in order to maintain their meters at acceptable accuracy.

Certain tests outlined in the following Parts are illustrated in schematic and in pictorial form. The schematic illustrates the internal connections of the Rotunda equipment so that these connections can be duplicated when this equipment is not available. The various circuits involved in the tests can be selected by means of switches without the necessity of changing connections when the illustrated equipment is used. This reduces the time required to test units and circuits on the vehicle.

Where applicable, the tests are divided into On The Vehicle and On The Test Bench procedures. Either procedure can be followed depending on the equipment available for the tests.

Trouble shooting or diagnosis is required before actual repairs can be made in the electrical system. Even where an obvious fault makes the replacement of a unit necessary, you must still find out why the unit failed. When a trouble is diagnosed correctly, unnecessary repairs are prevented, the time the vehicle is out of service will be decreased, and the repairs that are made will be permanent. The trouble shooting procedures given in the Truck Diagnosis Manual, Form No. FD7962-70T, will aid in making a correct diagnosis.

ON VEHICLE TESTS

Before performing charging system tests on the vehicle, note the complaint such as: slow cranking, battery dead or using an excessive amount of water, top of battery wet, ammeter shows charge at all times and/or no charge, alternator warning lamp does not come on and/or never goes out. This information will add in isolating the part of the system causing the problem. The battery must be in proper state of charge (at least 1.200 specific gravity).

VISUAL INSPECTION

1. If the vehicle is equipped with a fuse link, check the fuse link located between the starter solenoid and the alternator. Replace the fuse link if burned.
2. Check the battery posts and battery cable terminals for clean and tight connections. Remove the battery cables (if corroded), clean and install them securely.
3. Check for clean and tight wiring connections at the alternator, regulator and engine.
4. Check the alternator belt tension and tighten to specification (if necessary).

INDICATOR LIGHT-ALTERNATOR CHARGING SYSTEM

Normal Charge Indicator

With Ignition switch off .....Alternator lamp is off

With Ignition switch on (engine not running) .....Alternator lamp is on

With ignition switch on (engine running) .....Alternator lamp is off

1. If the charge indicator lamp does not come on with the ignition key in the ON position and the engine not running, check the I wiring circuit for an open circuit or burned out charge indicator lamp (ignition switch to regulator I terminal).
2. If the charge indicator light does not come on, disconnect the wiring plug connector at the regulator and connect a jumper wire from the I terminal of the regulator wiring plug to the negative battery post cable clamp.
3. The charge indicator lamp should go on with the ignition key turned to the ON position.
4. If the charge indicator bulb does not go on, check the bulb for continuity and replace (if burned out).
5. If the bulb is not burned out, an open circuit exists between the ignition switch and the regulator.

A good indication of a problem in the I wiring circuit (ignition switch to regulator I terminal) will show when the charge indicator light goes out with high engine rpm. This is caused by an open circuit in the 15 ohm resistor wire (connected in parallel with the indicator light) generally at the terminal point (either end of the resistor wire).

AMMETER-ALTERNATOR CHARGING SYSTEM

Normal Charge Indicator

With ignition switch off and no electrical load .....Ammeter should show 0 or center scale.

With ignition switch on engine running .....Needle deflects towards charge and returns toward center scale in two steps (fully charged battery).

With ignition switch off and headlamps on .....Ammeter should show between 0 and discharge scale.

Refer to the Ford Car and Truck Diagnosis Manual for diagnosis of the alternator charging system.

TESTS USING A VOLTMETER

When performing charging system tests with a voltmeter, turn OFF all lights and electrical components. Place the transmission in neutral and apply the parking brake. The battery must be charged to at least 1.200 specific gravity before starting the test.

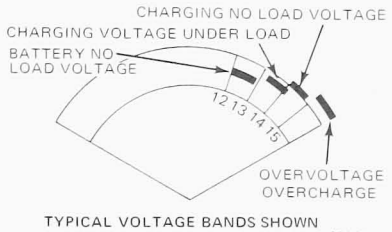

FIG. 2 Voltmeter Test Scale

Voltmeter Test Procedure

1. Connect the negative lead of the voltmeter to the negative battery cable clamp (not bolt or nut).
2. Connect the positive lead of the voltmeter to the positive battery cable clamp (not bolt or nut).
3. Record the battery voltage reading shown on the voltmeter scale.
4. Connect the red lead of a tachometer to the distributor terminal of the coil and the black tachometer lead to a good ground.
5. Then, start the engine and operate the engine at approximately 1500 rpm. With no other electrical load (foot off brake pedal and car doors closed), the voltmeter reading should increase 1 volt and not exceed 2 volts above the first recorded battery voltage reading. The reading should be taken when the voltmeter needle stops moving.
6. With the engine running, turn on the heater and/or air conditioner blower motor (high speed) and headlights on (high beam).
7. Increase the engine speed to 2000 rpm. The voltmeter should indicate a minimum of 0.5 volt above the first recorded battery voltage (Fig. 2).

If the above tests indicate proper voltage readings, the charging system is operating normally. Proceed to Test Results if a problem still exists.

Test Results

1. If the voltmeter reading indicates over voltage (more than 2.0 volts above battery voltage), stop the engine and check the ground connections between the regulator and alternator and/or regulator to engine. Clean and tighten connections securely and repeat the Voltmeter Test Procedure.
2. If over voltage condition still exists, disconnect the regulator wiring plug from the regulator and repeat the Voltmeter Test Procedure.
3. If over voltage condition disappears (voltmeter reads battery voltage), replace voltage regulator and repeat the voltmeter test procedure.
4. If over voltage still exists with the regulator wiring plug disconnected, repair the short in the wiring harness between the alternator and regulator. Then, replace the regulator and connect the regulator wiring plug to the regulator and repeat the Voltmeter Test Procedure.
5. If the voltmeter reading does not increase (one volt), check for the presence of battery voltage at the alternator BAT terminal and the regulator A terminal (Fig. 3). Repair the wiring if no voltage is present at these terminals, and repeat the Voltmeter Test Procedure.
6. If the voltmeter reading does not increase one volt above battery voltage, proceed to the next step before performing field circuit tests.
7. Before performing other tests, the field circuit (regulator plug to alternator) must be checked for a grounding condition. If the field circuit is grounded and the jumper wire is used as a check at the regulator wiring plug from the A to F terminals (Fig. 3), excessive current will cause heat damage to the regulator wiring plug terminals and may burn the jumper wire (Fig. 3). Also, if the field circuit was grounded, the connector wire inside the regulator will be burned open and an under voltage condition will result.
8. The field circuit should be checked with the regulator wiring plug disconnected and an ohmmeter connected from the F terminal of the regulator wiring plug to the battery ground. The ohmmeter should indicate between 4 and 250 ohms (Fig. 4).
9. A check for the regulator burned-open wire is made by connecting an ohmmeter from the I to F terminals of the regulator (Fig. 5). The reading should indicate 0 (no resistance). If the reading indicates approximately 10 ohms, the connector wire inside the regulator is open. The field circuit grounded condition must be found and repaired before installing a new regulator.

Field Circuit and Alternator Tests

1. If the field circuit is satisfactory, disconnect the regulator wiring plug at the regulator and connect the jumper wire from the A to the F terminals on the regulator wiring plug (Fig. 6).
2. Repeat the Voltmeter Test Procedure.
3. If the Voltmeter Test Procedure still indicates a problem (under voltage), remove the jumper wire from the regulator plug and leave the plug disconnected from the regulator. Then, connect a jumper wire to the FLD and BAT terminals on the alternator (Fig. 7).
4. Repeat the Voltmeter Test Procedure.
5. If the Voltmeter Test results are now satisfactory, repair the wiring harness from the alternator to the regulator. Then, remove the jumper wire at the alternator and connect the regulator wiring plug to the regulator.
6. Repeat the Voltmeter Test Procedure, to be sure the charging system is operating normally.
7. If the Voltmeter Test results still indicate (under voltage), repair or replace the alternator. With the jumper wire removed, connect the wiring to the alternator and regulator.
8. Repeat the Voltmeter Test Procedure.

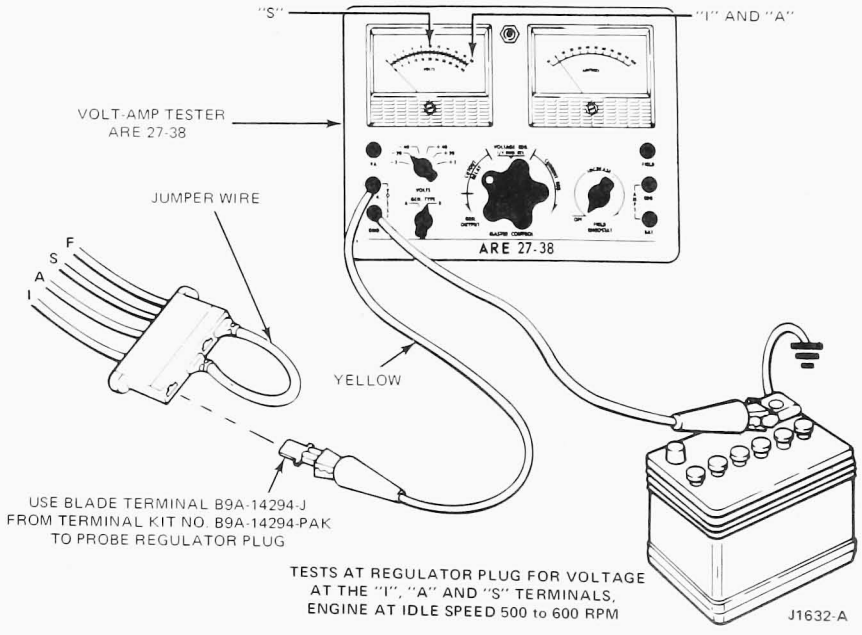

FIG. 3 Regulator Plug Voltage Tests

Regulator I and S Circuit Tests
S—Circuit With Ammeter

1. Connect the positive lead of the voltmeter to the S terminal of the regulator wiring plug (Fig. 3). Then, turn the ignition switch to the ON position. Do not start the engine.

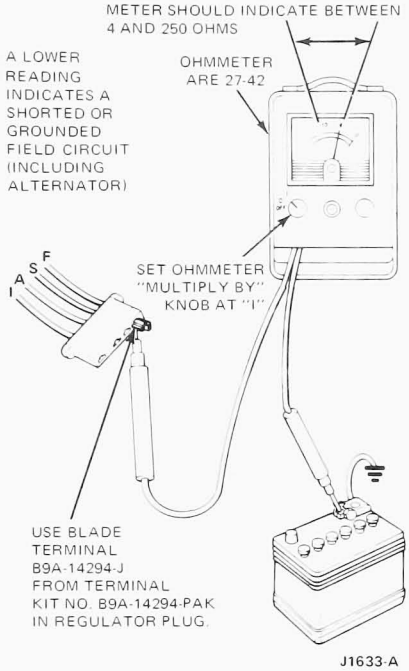

FIG. 4 Field Circuit Test

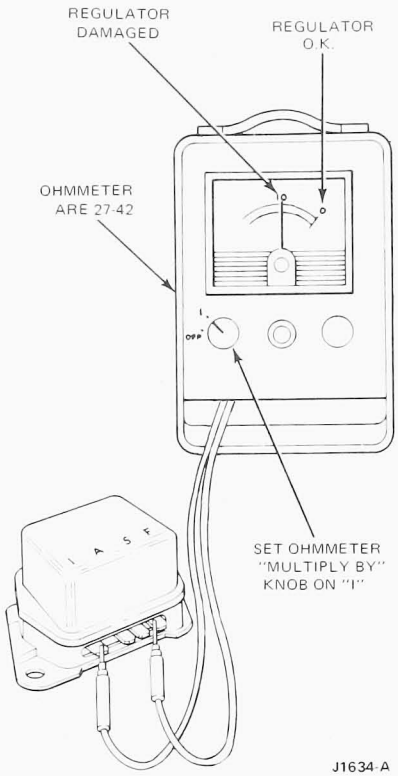

FIG. 5 Regulator Burned-Open Connector Wire Test

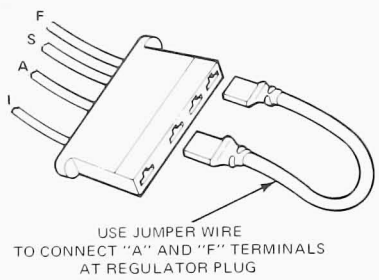

FIG. 6 Regulator Plug Jumper Wire Connections

2. The voltmeter reading should indicate battery voltage.
3. If there is no voltage reading, disconnect the positive voltmeter lead from the positive battery clamp and repair the S wire lead from the ignition switch to the regulator wiring plug.
4. Connect the positive voltmeter lead to the positive battery cable terminal and repeat the Voltmeter Test Procedure.

S and I Circuit—With Indicator Light

1. Disconnect the regulator wiring plug and install a jumper wire between the A and F terminals.

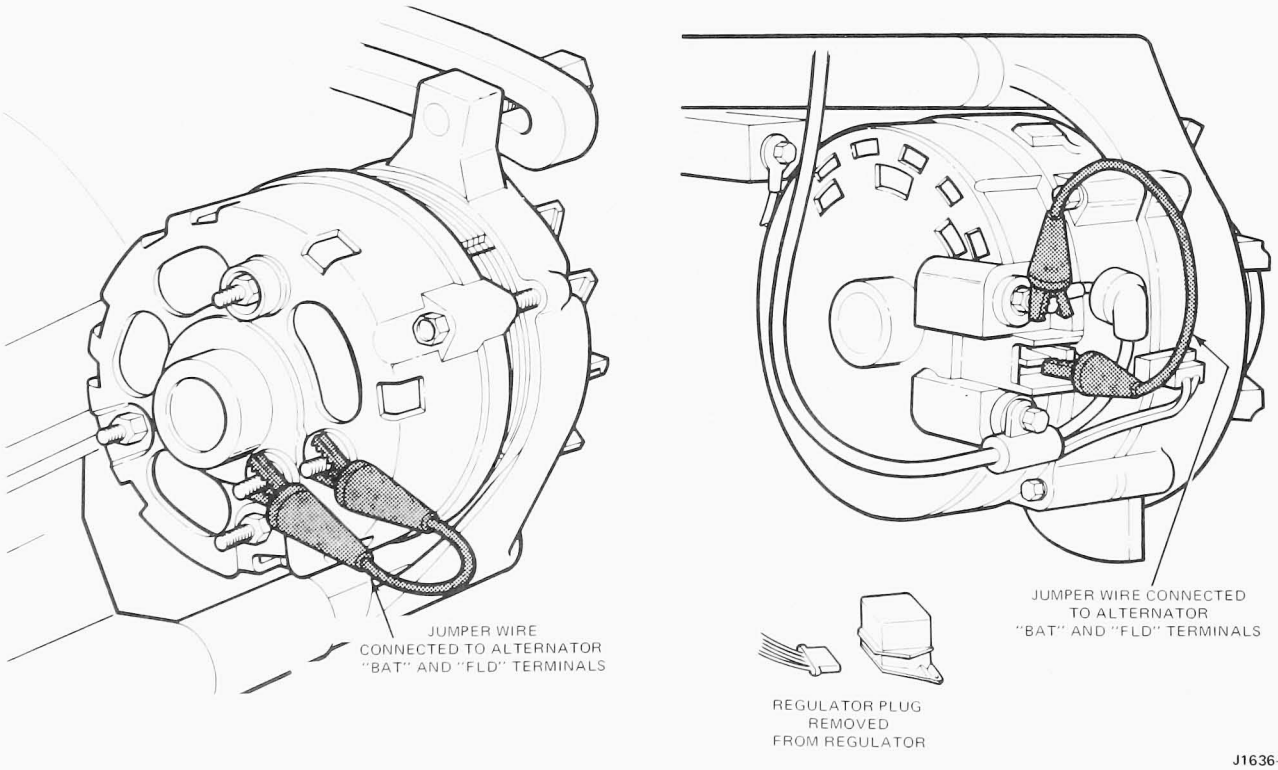

FIG. 7 Jumper Wire Connections

2. With the engine idling, connect the positive lead of the voltmeter to the S terminal and then to the I terminal of the regulator wiring plug (Fig. 3). The voltage of the S circuit should read approximately 1/2 of the I circuit.
3. If no voltage is present, repair the alternator or the wiring circuit at fault. Reconnect the positive voltmeter lead to the positive battery cable terminal and repeat the Voltmeter Test Procedure.
4. If the above voltage tests are satisfactory, install a new regulator.
5. Then, remove the jumper wire from the regulator wiring plug and connect the wiring plug to the regulator. Repeat the Voltmeter Test Procedure.

Diode Test—On Vehicle

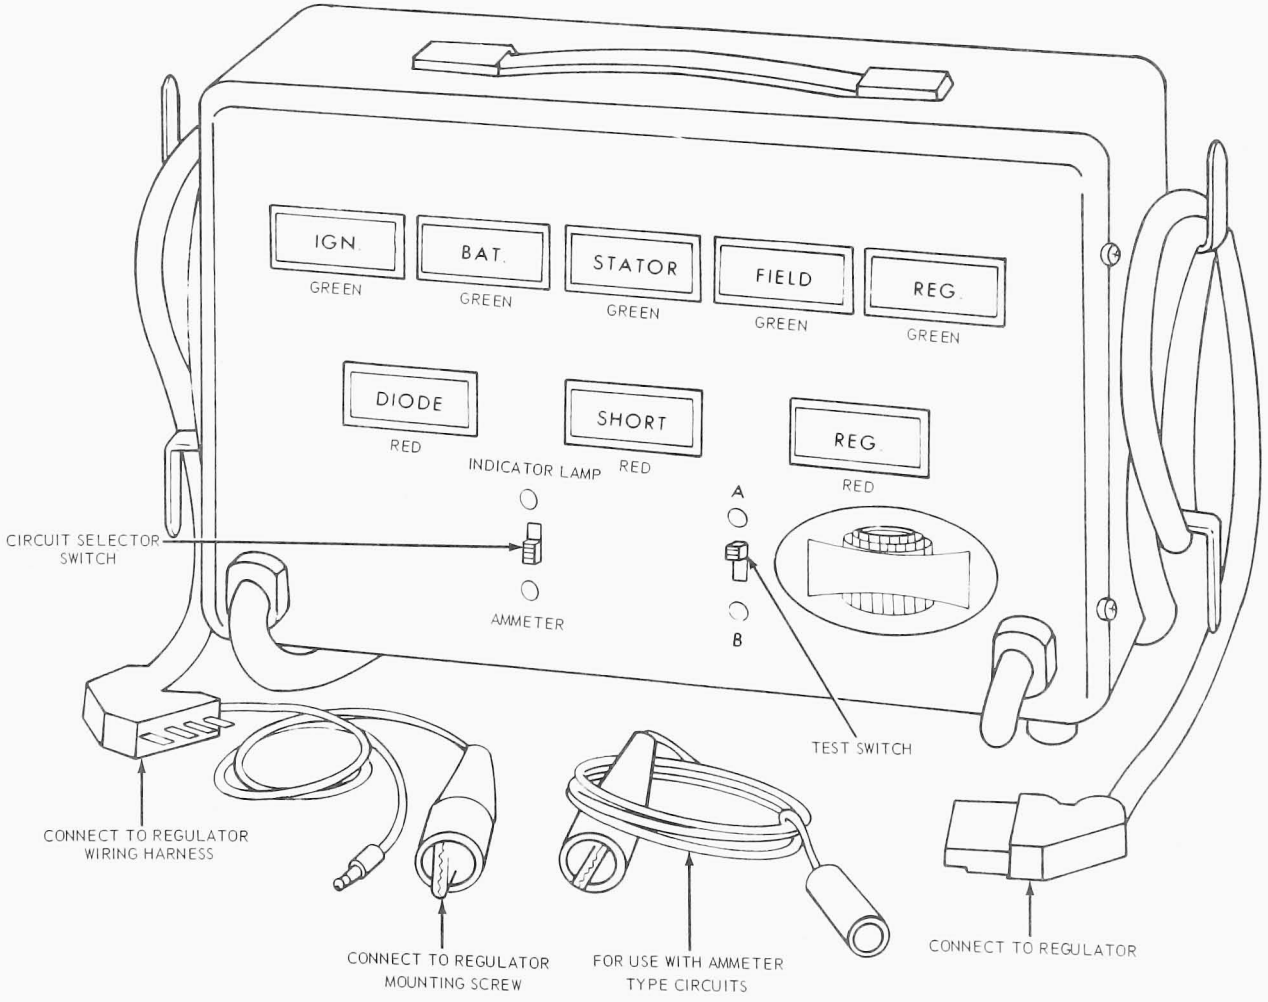
1. Disconnect the electric choke.
2. Disconnect voltage regulator wiring plug.
3. Connect a jumper between "A" and "F" terminal of voltage regulator wiring plug.
4. Connect voltmeter to battery cable clamps.
5. Start engine -let engine run at idle.
6. Read and record voltmeter reading.
7. Move positive voltmeter lead to "S" terminal in voltage regulator wiring plug.
8. Note voltmeter reading.

Test Results

1. If voltmeter reads 1/2 of battery voltage, diodes are okay.
2. If voltmeter reads approximately 1.5 volts, alternator has shorted **negative** diode, or a grounded stator winding.
3. If voltmeter reads approximately 1.5 volts less than battery voltage, alternator has shorted **positive** diode.
4. If voltmeter reads about 1.0 to 1.5 volts less than 1/2 battery voltage, alternator has an **open positive** diode.
5. If voltmeter reads about 1.0 to 1.5 volts more than 1/2 battery voltage, alternator has an **open** negative diode.
6. Connect the electric choke into the circuit after the test is completed.

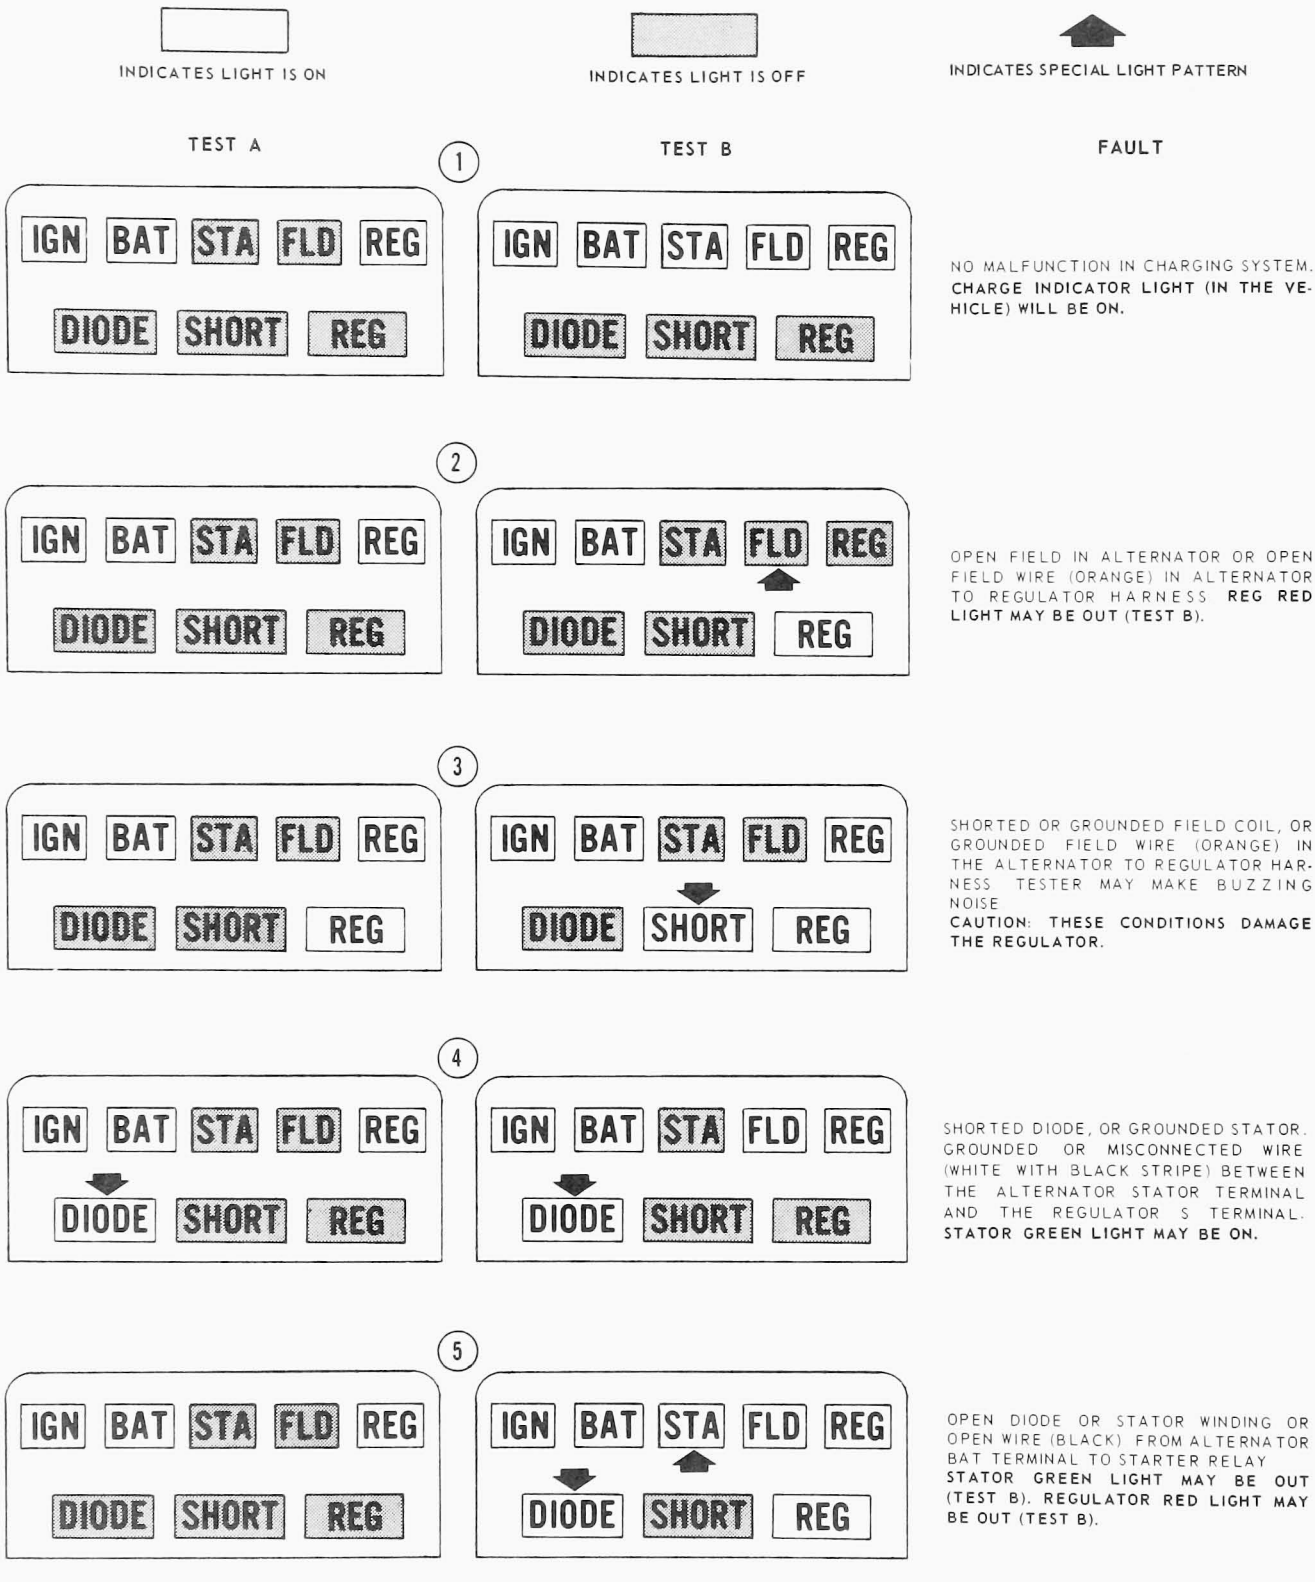
TESTS USING THE ROTUNDA ARE 20-22 ALTERNATOR REGULATOR TESTER

The general procedure is to connect the tester (Fig. 8) to the charging



J 1398-A

FIG. 8 ARE 20-22 Tester



NOTE: ALWAYS REPAIR MALFUNCTION AND RETEST

J1399-D

FIG. 9 ARE 20-22 Test Chart

NOTE: ALWAYS REPAIR MALFUNCTION AND RETEST

J1400-C

FIG. 10 ARE 20-22 Test Chart (continued)

system, start the engine, make two tests, and then compare the pattern of lights that appear on the tester to each set of patterns shown in Figs. 9 and 10. Follow the instructions given with the ARE 20-22 tester.

TESTS USING THE ROTUNDA ARE 27-38 VOLT-AMP-ALTERNATOR TESTER

The following test procedures make use of the Rotunda Volt-Amp Alternator Tester ARE 27-38.

Refer to the Wiring Diagram Manual, Form 7795-P-73 for schematics and locations of wiring harness. **Use care when connecting any test equipment to the alternator system, as the alternator output terminal is connected to the battery at all times.**

Alternator Output Test On Engine

When the alternator output test is conducted off the car, a test bench must be used. Follow the procedure given by the test bench equipment manufacturer. When the alternator is removed from the vehicle for this purpose, always disconnect the battery ground cable as the alternator output connector is connected to the battery at all times.

To test the output of the alternator on the vehicle, proceed as follows:

Test Procedure

1. Check the alternator drive belt tension. Place the transmission in neutral or park and apply the parking brake. Make the connections and tester knob adjustments as shown in Fig. 11 (Output Test). Be sure that the field rheostat knob is at the OFF position at the start of this test.
2. Close the battery adapter switch. Start the engine, then open the battery adapter switch.
3. Increase the engine speed to approximately 2000 rpm (use a tachometer following the manufacturers instructions). Turn off all lights and electrical accessories.
4. Turn the field rheostat clockwise until 15 volts is indicated on the voltmeter upper scale. Turn the master control clockwise until the voltmeter indicates between 11 and 12 volts. Holding the master control in this position, turn the field rheostat clockwise to its maximum rotation. Turn the master control

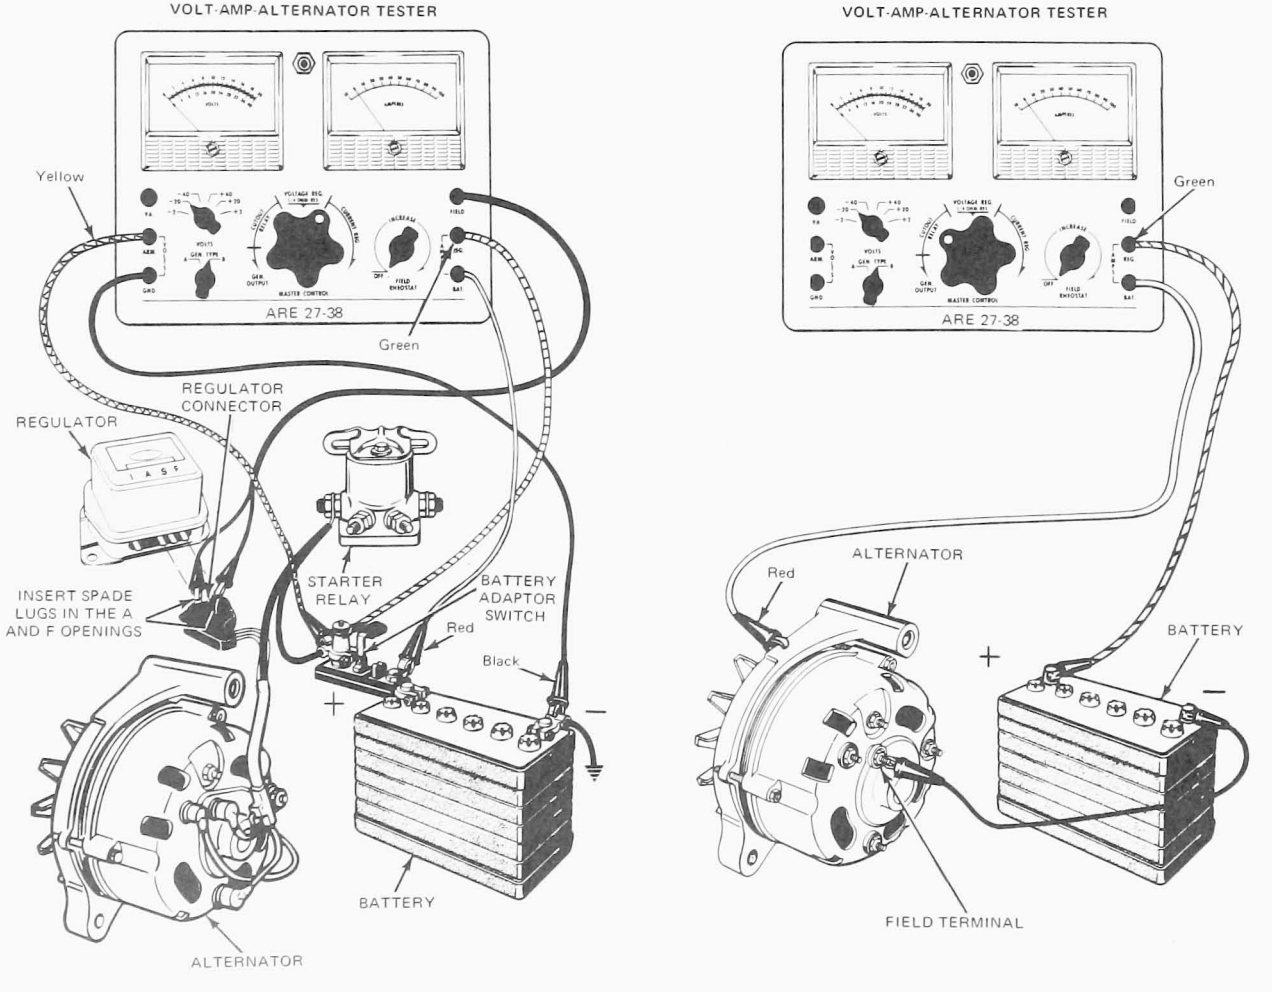


FIG. 11 Alternator Tests

counter clockwise until the voltmeter indicates 15 volts. Observe the ammeter reading. Add 2 amperes to this reading to obtain alternator output. If rated output cannot be obtained, increase the engine speed to 2900 rpm and repeat this step.

5. Return the field rheostat knob to OFF, release the master control knob, and stop the engine. Disconnect the test equipment, if no further tests are to be made.

If the alternator output is not O.K., it will be necessary to remove the alternator from the vehicle and perform the necessary bench tests to locate the problem.

An output of 2 to 5 amperes below specification usually indicates an open alternator diode. An output approximately 10 amperes below specification usually indicates a shorted alternator diode. An alternator with a shorted diode will usually whine, which will be most noticeable at idle speeds.

Stator Neutral Voltage Test—On Engine

The alternator STA terminal is connected to the stator coil neutral or center point of the alternator windings. The voltage generated at this point is used to close the field relay in the charge indicator light system.

To test for the stator neutral voltage, disconnect the regulator connector plug from the regulator. Make the connections and tester knob adjustments as shown in Fig. 12.

Start the engine and run it at 1000 rpm (use a tachometer). Turn off all lights and accessories. Rotate the field rheostat clockwise until at least 6 volts is indicated on the voltmeter upper scale. If 6 volts or more is not obtained, remove the alternator and perform the diode and stator tests to determine which part of the alternator is damaged.

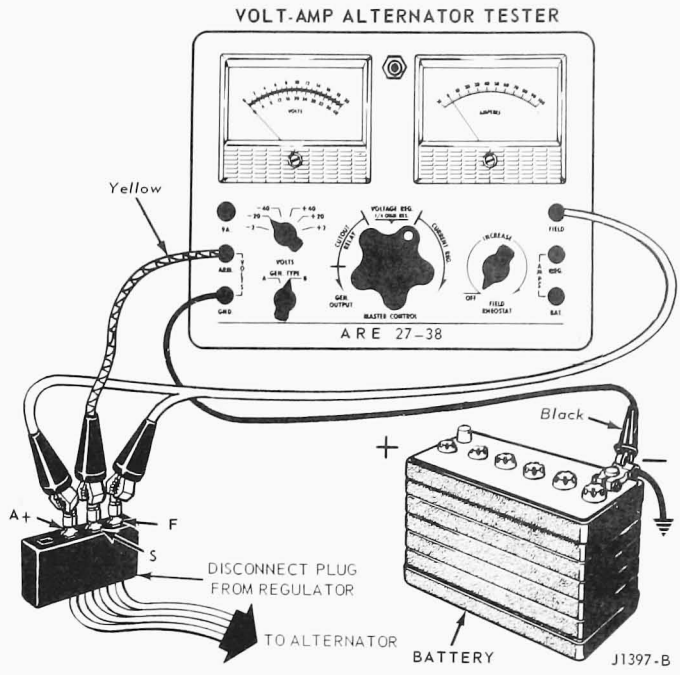

FIG. 12 Stator Neutral Voltage Test

BENCH TESTS

RECTIFIER SHORT OR GROUNDED AND STATOR GROUNDED TEST—ON BENCH

These tests are performed with an ARE 27-42 ohmmeter. Set the Multiply By knob at 10, and calibrate the ohmmeter as directed inside the instrument cover.

Contact one ohmmeter probe to the alternator BAT terminal (Fig. 13) and the other probe to the STA terminal (rear blade terminal). Then, reverse the ohmmeter probes and repeat the test. A reading of about 60 ohms should be obtained in one direction and no needle movement with the probes reversed. A reading in both directions indicates a bad positive diode, a grounded positive diode plate or a grounded BAT terminal.

Perform the same test using the STA and GND (ground) terminals of the alternator. A reading in both directions indicates either a bad negative diode, a grounded stator winding, a grounded stator terminal, a grounded positive diode plate, or a grounded BAT terminal.

Infinite readings (no needle movement) in all four probe positions in the preceeding tests indicates an open STA terminal lead connection inside the alternator.

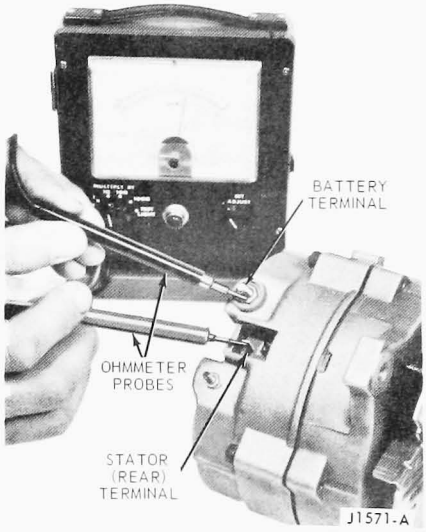

FIG. 13 Rectifier Short or Grounded and Stator Grounded Test

FIELD OPEN OR SHORT CIRCUIT TEST—ON BENCH

This test is performed with an ohmmeter (Tool ARE 27-42). Set the ohmmeter Multiply By knob at 1 and calibrate the ohmmeter as directed inside the instrument cover.

Contact the alternator field terminal with one probe and the ground terminal with the other probe (Fig. 14). Then, spin the alternator pulley. The ohmmeter reading should be between 4 and 250 ohms, and should fluctuate while the pulley is turning. An infinite reading (no meter movement) indicates an open brush lead, worn or stuck brushes, or a bad rotor assembly. An ohmmeter reading less than 4 ohms indicates a grounded brush assembly, a grounded field terminal or a bad rotor.

DIODE TEST—ON BENCH

Remove the rectifier assembly from the alternator as outlined in Section 5. Set the ohmmeter Multiply By knob at 10 and calibrate the meter as directed inside the cover.

To test one set of diodes, contact one probe to the terminal bolt as shown in Figs. 15, 16 and 17 and contact each of

the three stator lead terminals with the other probe. Reverse the probes and repeat the test. All diodes should show a low reading of about 60 ohms in one direction, and an infinite reading (no needle movement) with the probes reversed. Repeat the preceeding tests for the other set of diodes except that the other terminal screw is used.

If the meter readings are not as specified, replace the rectifier assembly.

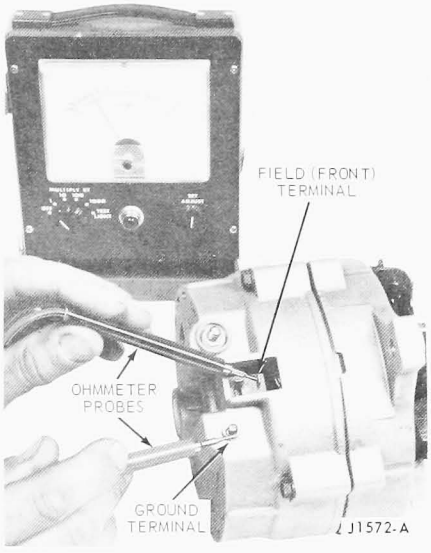

FIG. 14 Field Open or Short Circuit Test

STATOR COIL OPEN OR GROUNDED TEST—ON BENCH

These tests are made to determine if the stator coil is operating properly. Disassemble the stator from the alternator as outlined under Disassembly in Section 5.

Set the ARE 27-42 ohmmeter Multiply By knob at 1, and calibrate the meter as directed inside the cover. Connect the ohmmeter probes between each pair of stator leads (3 different ways). The ohmmeter must show equal readings for each pair of stator leads. Replace the stator if the readings are not the same.

Set the ARE 27-42 ohmmeter Multiply By knob at 1000. Connect the ohmmeter probes to one of the stator leads and to the stator laminated core. Be sure that the probe makes a good electrical connection with the stator core. The meter should show an infinite reading (no meter movement). If the meter does not indicate an infinite reading (needle moves), the stator winding is shorted to the core and must be replaced. Repeat this test for each of the stator leads.

ROTOR OPEN OR SHORT CIRCUIT TEST—ON BENCH

Disassemble the front housing and rotor from the rear housing and stator as outlined under Disassembly in Section 5. Set the ohmmeter (ARE 27-42) Multiply By knob at 1 and calibrate the meter as directed inside the ohmmeter cover.

Contact each ohmmeter probe to a rotor slip ring. The meter reading should be 4 or 5 ohms. A higher reading indicates a damaged slip ring solder connection or a broken wire. A lower reading indicates a shorted wire or slip ring. Replace the rotor if it is damaged and cannot be repaired.

Contact one ohmmeter probe to a slip ring and the other probe to the rotor shaft. The meter reading should be infinite (no deflection). A reading other than infinite indicates the rotor is shorted to the shaft. Inspect the slip ring soldered terminals to be sure they are not bent and touching the rotor shaft, or that excess solder is grounding the rotor coil connections to the shaft. Replace the rotor if it is shorted and cannot be repaired.

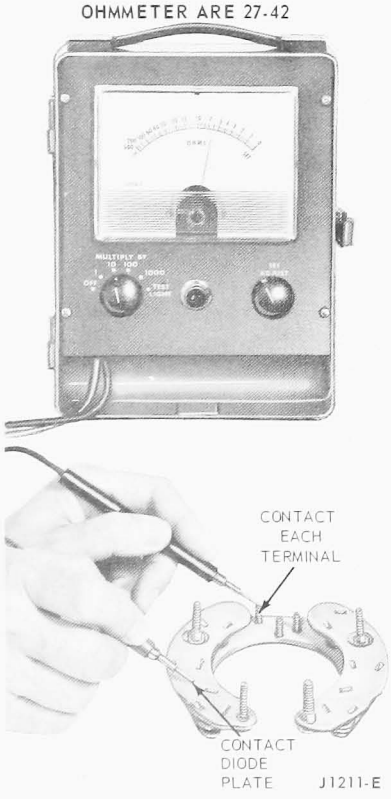

FIG. 15 Diode Test—Rear Terminal Alternator Except 61-Ampere

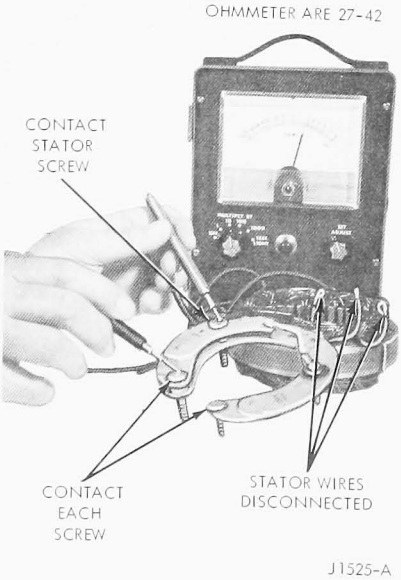

FIG. 16 Diode Test—61-Ampere Alternator

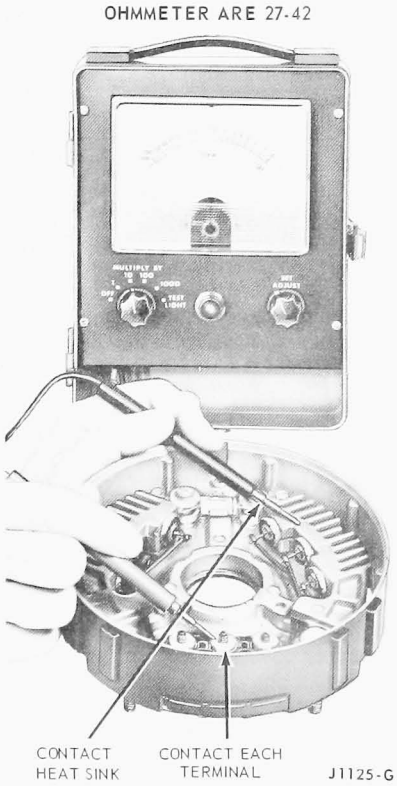

FIG. 17 Diode Test—Leece Neville Alternators

FUSE LINK CONTINUITY TEST

LIGHT TRUCK, ECONOLINE AND CLUB WAGON WITH AN AMMETER

Make certain that the battery is OK, then turn on the headlights or any accessory. If the headlights or accessory do not operate, the fuse link is probably burned out.

LIGHT TRUCK, ECONOLINE AND CLUB WAGON WITH AN INDICATOR LIGHT, BRONCO AND P-SERIES

Make certain the battery is OK, then check with a voltmeter for battery voltage at the alternator BAT. terminal. No voltage indicates that the fuse link is probably burned out.

REMOVAL AND INSTALLATION

FUSE LINK REPLACEMENT

1. Procure the proper service fuse link for the vehicle being repaired. The fuse links have an eyelet terminal for a 5/16 inch stud on one end. If the terminal is not required, cut off the fuse link as close to the terminal as possible and strip approximately 3/8 inch of insulation from the cut end.
2. Disconnect the battery ground cable.
3. Disconnect the fuse link terminal at the starter relay.
4. Remove the complete fuse link at the splice.
5. Cut out the original splice, then splice and solder the new fuse link with the existing wires from the original splice. Use rosin-core solder. Wrap the splices completely with vinyl electrician's tape.
   If a vehicle has two wires connected to the fuse-link eyelet, cut the fuse link from the eyelet and position the second wire with eyelet back on the starter relay terminal.
6. Securely connect the eyelet terminal(s) to the battery stud on the starter relay.
7. Install the repaired wiring as before using existing clips if provided.
8. Connect the battery ground cable.

PART 31-02 Batteries

This Information Applies To All Models

COMPONENT INDEX	Page	COMPONENT INDEX	Page
SPECIFICATIONS	02-02	Rotunda Battery Starter Tester ARE 16-31	02-01
TESTING		Rotunda Cell Analyzer	
Capacity Test – Battery	02-01	SRECA – 200	02-01

TESTING

Tests are made on a battery to determine the state of charge and also the condition. The ultimate result of these tests is to show that the battery is good, needs recharging, or must be replaced.

If a battery has failed, is low in charge, or requires water frequently, good service demands that the reason for this condition be found. It may be necessary to follow trouble shooting procedures to locate the cause of the trouble.

Refer to the Truck Diagnosis Manual, Form No. FD7962-70T, for battery trouble shooting procedures.

Hydrogen and oxygen gases are produced during normal battery operation. this gas mixture can explode if flames or sparks are brought near the vent openings of the battery. The sulphuric acid in the battery electrolyte can cause a serious burn if spilled on the skin or spattered in the eyes. It should be flushed away with large quantities of clear water.

Particular care should be used when connecting a booster battery in order to prevent sparks. Be certain to connect positive terminal to positive terminal and negative terminal to negative terminal.

Before attempting to test a battery, it is important that it be given a thorough visual examination to determine if it has been damaged. The presence of moisture on the outside of the case and/or low electrolyte level in one or more of the cells are indications of possible battery damage.

Original equipment batteries incorporate a single one-piece cover which completely seals the top of the battery and the individual cell connectors. This cover must not be pierced with test probes to perform individual cell tests.

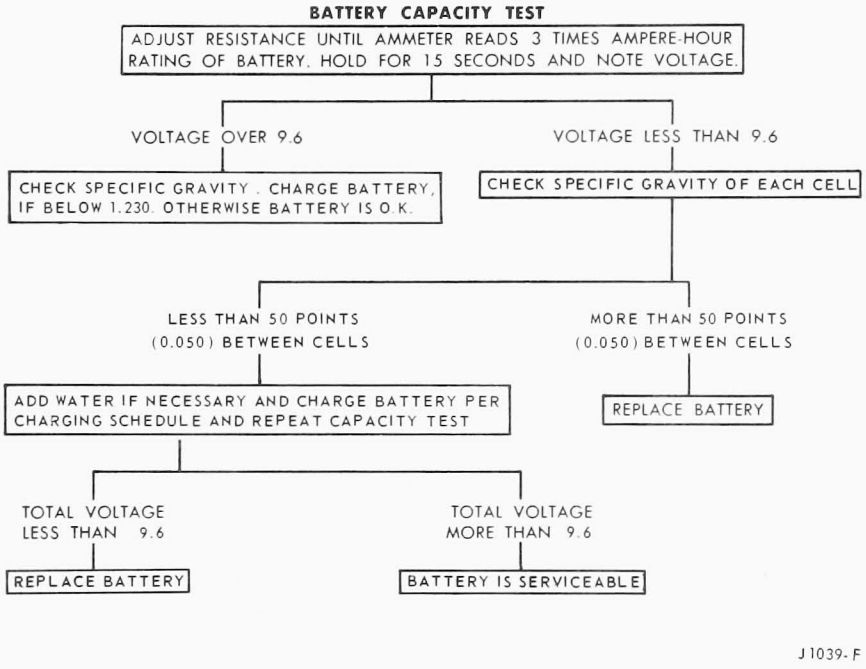

FIG. 1 Battery Capacity Test Outline

TESTS USING THE ROTUNDA CELL ANALYZER (SRECA-200)

The Rotunda Cell Analyzer (SRECA-200) measures the individual cell voltages by inserting probes into the cell openings. Follow the instructions that come with the unit.

A battery can also be tested by determining its ability to deliver current. This may be determined by conducting a Battery Capacity Test. Figure 1 shows the battery capacity test in outline form.

TESTS USING THE ROTUNDA BATTERY-STARTER TESTER ARE 16-31

BATTERY CAPACITY TEST

A high rate discharge tester (Rotunda Battery-Starter Tester ARE 16-31) in conjunction with a voltmeter is used for this test.

1. Turn the control knob on the Battery-Starter Tester to the OFF positio-

2. Turn the voltmeter selector switch to the 20-volt position.
3. Connect both positive test leads to the positive battery post and both negative test leads to the negative battery post. **The voltmeter clips must contact the battery posts and not the high rate discharge tester clips. Unless this is done the actual battery terminal voltage will not be indicated.**
4. Turn the load control knob in a clockwise direction until the ammeter reads three times the ampere hour rating of the battery. (A 45 ampere-hour battery should be tested at 135 amperes load).
5. With the ammeter reading the required load for 15 seconds, note the voltmeter reading. **Avoid leaving the high discharge load on the battery for periods longer than 15 seconds.**
6. If the voltmeter reading is 9.6 volts or more, the battery has good output capacity and will readily accept a charge, if required. Check the specific gravity. If the specific gravity reading is 1.230 or below, add water if necessary and charge the battery until it is fully charged (Fig. 1). **Always disconnect the battery ground cable when charging the battery.**

The battery is fully charged when the cells are all gassing freely and the specific gravity ceases to rise for three successive readings taken at hourly intervals. Additional battery testing will not be necessary after the battery has been properly charged.

7. If the voltage reading obtained during the capacity test is below 9.6 volts, check the specific gravity of each cell.
8. If the difference between any two cells is more than 50 points (0.050), the battery is not satisfactory for service and should be replaced.
9. If the difference between cells is less than 50 points (0.050), the battery should be charged according to the charging schedule in the Specifications Section. Batteries that are completely discharged may not accept a fast charge. If this is found, the battery should be slow charged until the charge rate goes up and it will accept the fast charge. This may require up to four hours of slow charge. In some cases the electrolyte level may be too low to obtain a specific gravity reading. In such cases water should be added until the electrolyte level just covers the ring in the filler well, then charge the battery at 35 amperes for the maximum charging time indicated in Specifications for the capacity of the battery being tested.
10. After the battery has been charged, repeat the capacity test. If the capacity test battery voltage is still less than 9.6 volts, replace the battery. If the voltage is 9.6 volts or more, the battery is satisfactory for service.
11. If the battery is found to be discharged only, check for a loose fan belt, loose electrical connections and charging system performance.

DESCRIPTION AND OPERATION

ALTERNATOR

The alternator charging system is a negative ground system, and consists of an alternator, a regulator, a charge indicator, a storage battery, a fuse link on some models and associated wiring. Refer to the Wiring Diagram Manual, Form 7795P-73, for schematics and locations of wiring harnesses.

The alternator is belt driven from the engine. Current is supplied from the alternator-regulator system to the rotating field of the alternator through two brushes to two slip rings.

The alternator produces power in the form of alternating current. The alternating current is rectified to direct current by six diodes (eight diodes in 61 ampere alternators). The alternator regulator automatically adjusts the alternator field current to maintain the alternator output voltage within prescribed limits to correctly charge the battery.

If a charge indicator lamp is used in the charging system (Fig. 1), the system operation is as follows: When the ignition switch is turned ON, a small electrical current flows through the lamp filament (turning the lamp ON) and through the alternator regulator to the alternator field. When the engine is started, the alternator field rotates and produces a voltage in the stator winding. When the voltage at the alternator stator terminal reaches about 3 volts, the regulator field relay closes. This puts the same voltage potential on both sides of the charge indicator lamp causing it to go out. When the field relay has closed, current passes through the regulator A terminal and is metered to the alternator field.

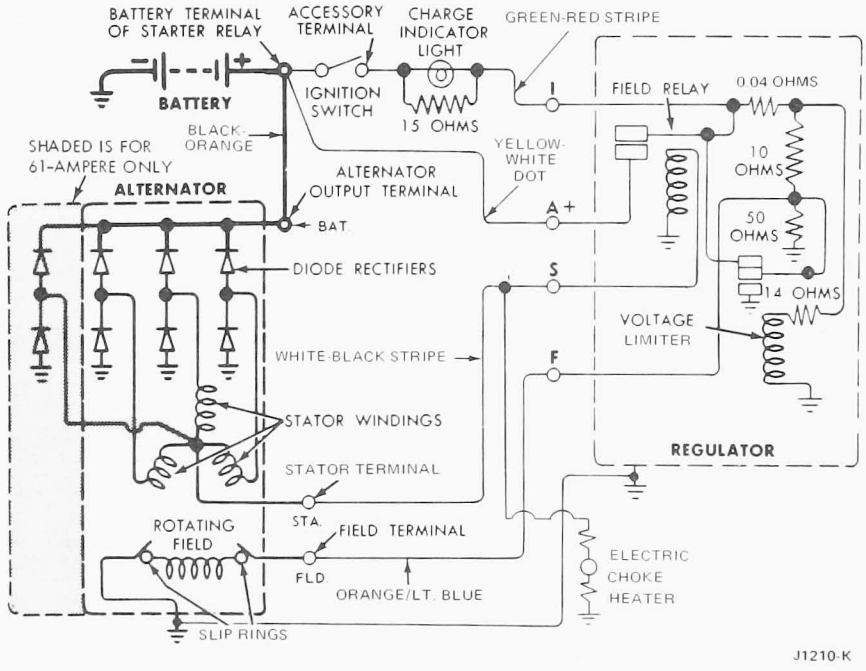

FIG. 1 Alternator Charging System—Indicator Light

If an ammeter is used in the charging system (Fig. 2), the regulator I terminal and the alternator stator terminal are not used. When the ignition switch is turned ON, the field relay closes and electrical current passes through the regulator A terminal and is metered to the alternator field. When the engine is started, the alternator field rotates causing the alternator to operate. The ammeter indicates current flow into (charge) or out of (discharge) the vehicle battery.

Fuse links are included in the charging system wiring on some models (Part 31-01). This fuse link is used to prevent damage to the wiring harness and alternator if the wiring harness should become grounded, or if a booster battery is connected to the charging system with the wrong polarity.

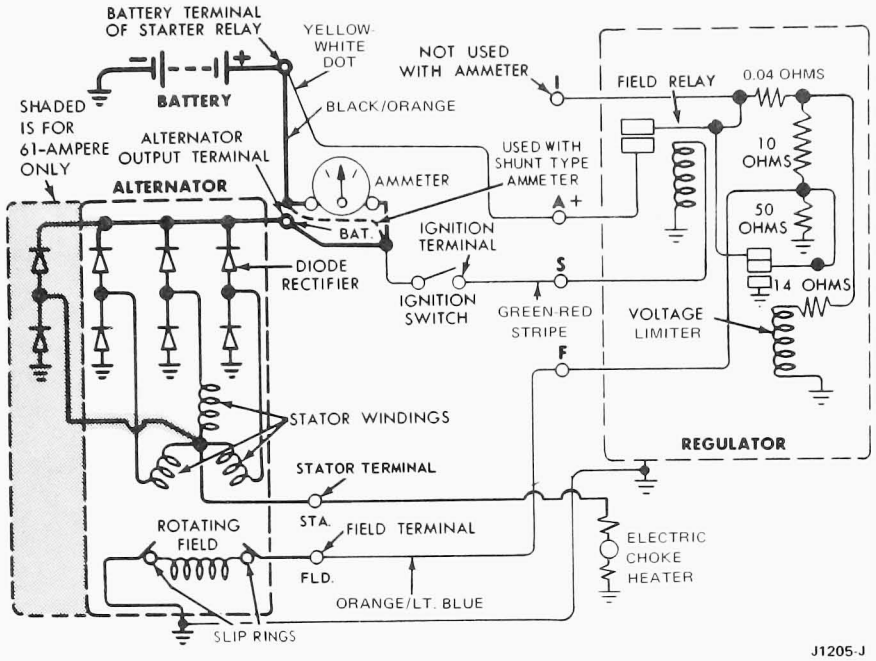

FIG. 2 Alternator Charging System—Ammeter

TESTING

Refer to the Ford Car and Truck Diagnosis Manual for diagnosis of the alternator charging system. Test procedures for the charging system are given in Part 31-01 of this manual. Check the alternator drive belt and adjust it to specification (Specifications at end of this Part), before proceeding with any tests. Check and tighten all connectors at the starter relay and battery. DO NOT OPERATE THE ENGINE WITH THE BATTERY DISCONNECTED.

ADJUSTMENTS

BELT ADJUSTMENT

1. Check the belt tension with tool T63L-8620-A. The belt should be within specifications (Specifications Section at end of this Part).
2. If the belt is not within specification, loosen the alternator mounting bolt to a snug position and loosen the adjusting arm bolts.
3. **Apply pressure on the alternator front housing only** and tighten the adjusting arm to alternator bolt.
4. Check the belt tension using Tool T63L-8620-A. Adjust the belt for specified tension.
5. Tighten all mounting bolts to 22-32 ft-lb torque.

REMOVAL AND INSTALLATION

Removal

1. Disconnect the battery ground cable.
2. Loosen the alternator mounting bolts and remove the adjustment arm-to-alternator attaching bolt.
3. Remove the electrical connectors from the alternator. The stator and field connectors are the push-on type. They should be pulled straight off the terminal studs to prevent damage to them.
4. Disengage the alternator belt. Remove the alternator mounting bolt, and remove the alternator.

Installation

1. Install the alternator wiring harness (Figs. 3 or 4). Position the alternator to the engine, and install the spacer (if used) and the alternator mounting bolt. Tighten the bolt only finger tight.
2. Install the adjustment arm-to-alternator attaching bolt.
3. Adjust the belt tension using tool T63L-8620-A. **Apply pressure on the alternator front housing only,**

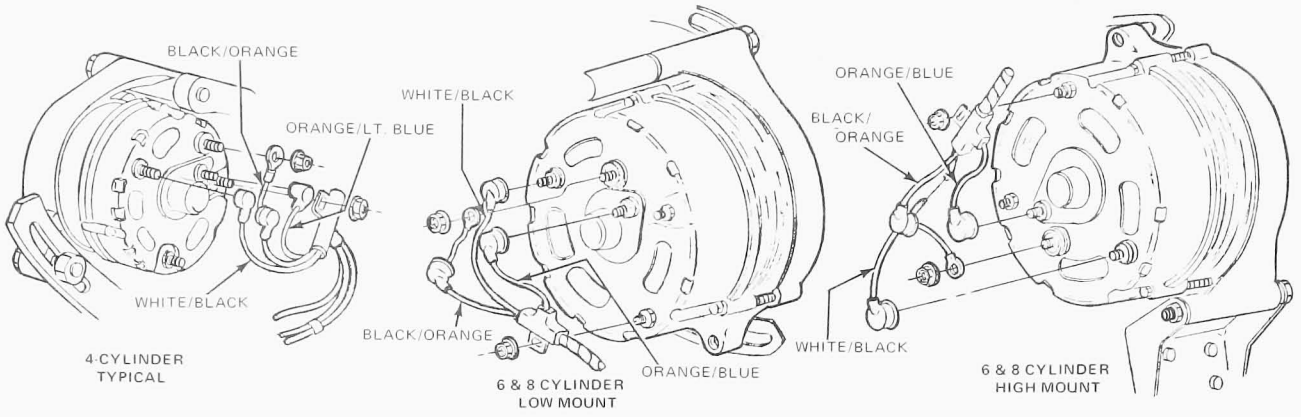

FIG. 3 Wiring Harness Connection—Typical Except 70 and 90-Ampere Alternator

when tightening the belt.

Tighten the adjusting arm bolts to 23-33 ft-lb torque, and the mounting bolt to 50-60 ft-lb torque.

4. Connect the battery ground cable.

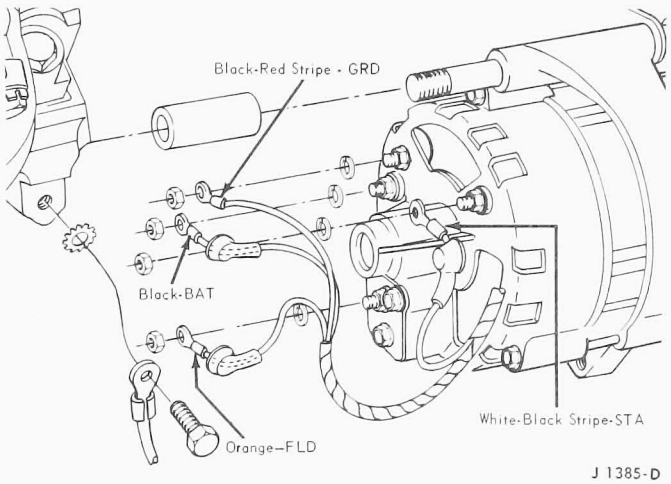

FIG. 4 Wiring Harness Connections—70 and 90-Ampere Alternators

OVERHAUL

G.P.D. REAR TERMINAL ALTERNATOR—EXCEPT 70 AND 90-AMPERE

Disassembly

Fig. 5 shows a disassembled view of the G.P.D. rear termial alternator.

1. Mark both end housings and the stator with a scribe mark for assembly.
2. Remove the three housing through bolts.
3. Separate the front housing and rotor from the stator and rear housing.
4. Remove all the nuts and insulators from the rear housing and remove the rear housing from the stator and rectifier assembly.
5. Remove the brush holder mounting screws and remove the holder, brushes, brush springs, insulator and terminal.
6. If replacement is necessary, press the bearing from the rear housing, supporting the housing on the inner boss.
7. If the rectifier assembly is being replaced, unsolder the stator leads from rectifier terminals, and separate the stator from the rectifier assembly. Use a 100-watt soldering iron.
8. Original production alternators will have one of three types of rectifier assembly circuit boards (Fig. 6); one has the circuit board spaced away from the diode plates with the diodes exposed. Another type is a single circuit board with built-in diodes. The third type circuit board has built-in diodes with an additional booster diode plate containing two diodes. This circuit board is used only in the 61-ampere alternator.

If the alternator rectifier has an exposed diode circuit board, remove the screws from the rectifier by rotating the bolt heads 1/4 turn clockwise to unlock

them and then remove the screws (Fig. 6). Push the stator terminal straight out on a rectifier with the diodes built into the circuit board (Fig. 6). Avoid turning the screw while removing, to make certain that the straight knurl will engage the insulators when installing. Do not remove the grounded screw (Fig. 7).

On a 61-ampere alternator rectifier, press the stator terminal screw from the circuit board as shown in Fig. 8. When the terminal screws has moved about 1/4 inch, remove the nut from the end of the screw and lift the screw from the circuit board. **Do not twist the screw in the circuit board.**

9. Remove the drive pulley nut with the tool shown in Fig. 9; then, pull the lock washer, pulley, fan, fan spacer, rotor and rotor stop from the rotor shaft.
10. Remove the three screws that hold the front end bearing retainer, and remove the retainer. If the bearing is damaged or has lost its lubricant, support the housing close to the bearing boss, and press out the old bearing from the housing.
11. Perform a diode test and a field open or short circuit test (Refer to Testing in this Part).

Assembly

1. The rotor, stator and bearings must not be cleaned with solvent. Wipe these parts off with a clean cloth.
2. Press the front bearing in the front housing bearing boss **(put pressure on the bearing outer race only)**, and install the bearing retainer (Fig. 5).
3. If the stop-ring on the rotor drive shaft was damaged, install a new

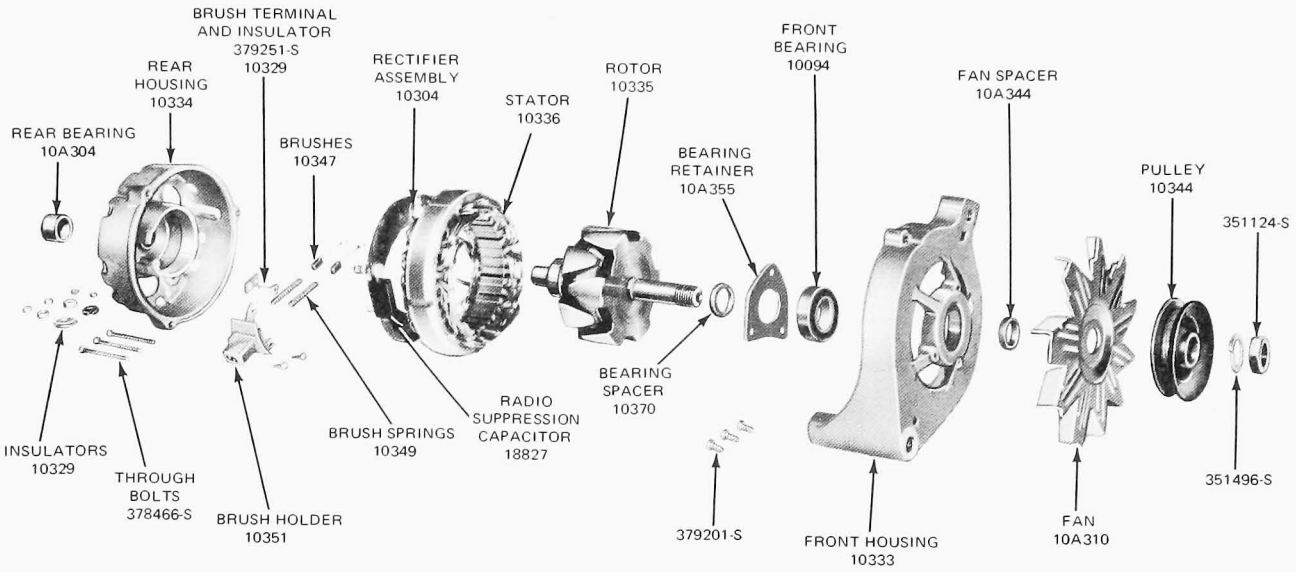

FIG. 5 Disassembled Alternator

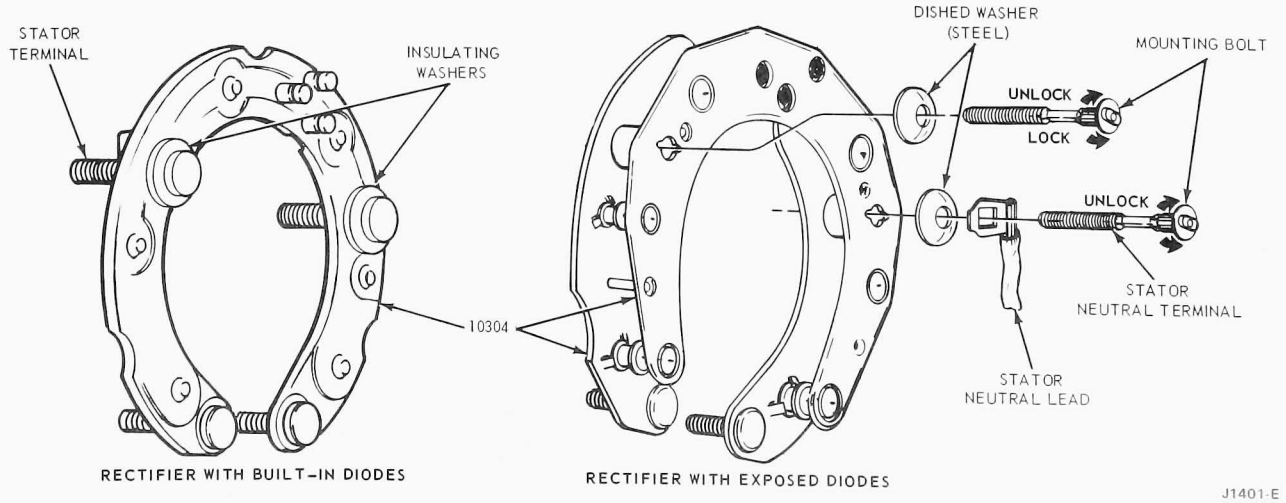

FIG. 6 Rectifier Assembly

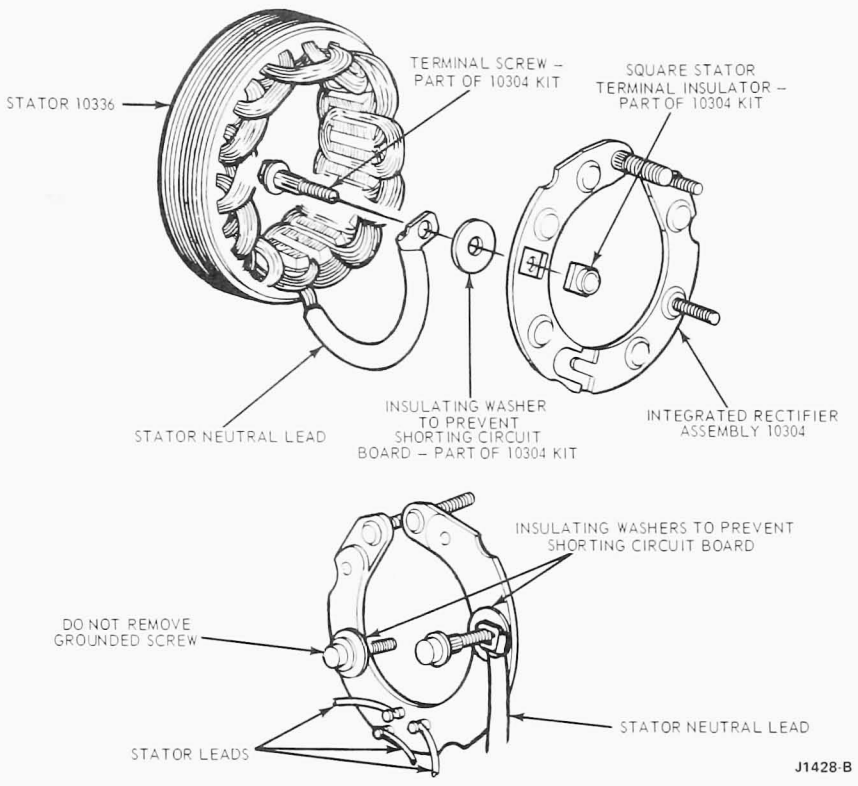

FIG. 7 Stator Terminal Installation—Integral Rectifier Circuit Board

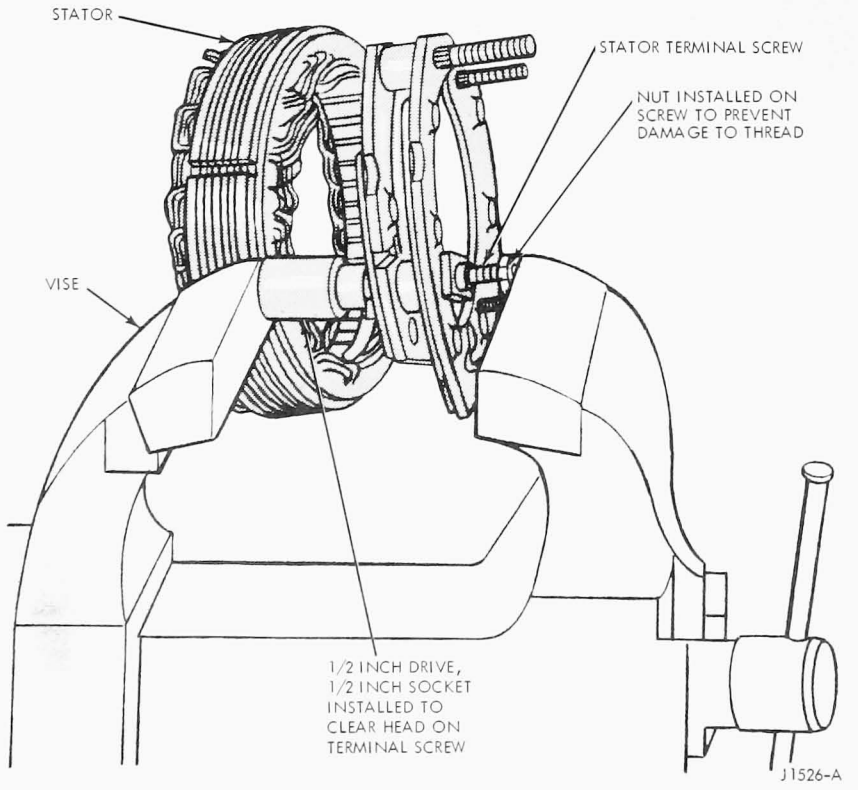

FIG. 8 Stator Terminal Screw Removal—61-Ampere Alternator

stop-ring. Push the new ring on the shaft and into the groove. **Do not open the ring with snap ring pliers as permanent damage will result.**

4. Position the rotor stop on the drive shaft with the recessed side against the stop-ring.
5. Position the front housing, fan spacer, fan, pulley and lock washer on the drive shaft and install the retaining nut. Tighten the retaining nut with the tool shown in Fig. 9 to the specified torque (Specifications Section in this Part).
6. If the rear housing bearing was removed, support the housing on the inner boss and press in a new bearing flush with the outer end surface.
7. Place the brush springs, brushes, brush terminal and terminal insulator in the brush holder and hold the brushes in position by inserting a piece of stiff wire in the brush holder as shown in Fig. 10.

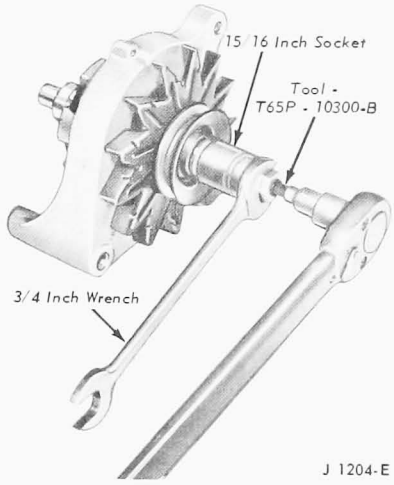

FIG. 9 Pulley Removal

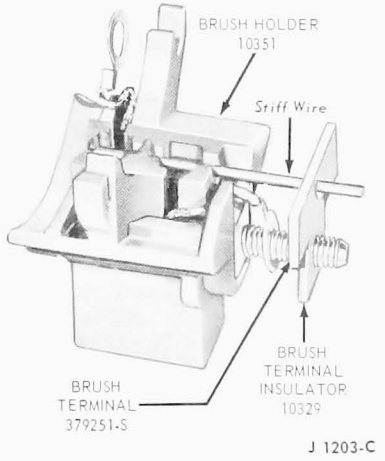

FIG. 10 Brush Holder Assembly

8. Position the brush holder assembly in the rear housing and install the mounting screws. Position the brush leads in the brush holder as shown in fig. 11.
9. Wrap the three stator winding leads around the rectifier terminals and solder them. Use a 100-watt soldering iron and rosin-core solder. Position the stator neutral lead eyelet on the stator terminal screw and install the screw in the rectifier assembly (Fig. 12).
10. For a rectifier with the diodes exposed, insert the special screws through the wire lug, dished washers and circuit board (Fig. 6). Turn them 1/4 turn counterclockwise to lock them. For single circuit boards with built-in diodes, insert the screws straight through the wire lug, insulating washer and rectifier into the insulator (Fig. 7).

The dished washers are to be used only on the circuit board with exposed diodes (Fig. 6). If they are used on the single circuit board, a short circuit will occur. A flat insulating washer is to be used between the stator terminal and the board, when a single circuit board is used (Fig. 7).

11. For a rectifier with a booster diode plate (61-ampere only), proceed as follows:
    a. Position the stator wire terminal on the stator terminal screw, and position the screw into the rectifier. Position the square insulator over the screw and into the square hole in the rectifier (Fig. 13).

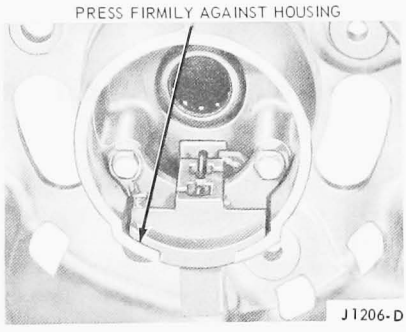

FIG. 11 Brush Lead Positions

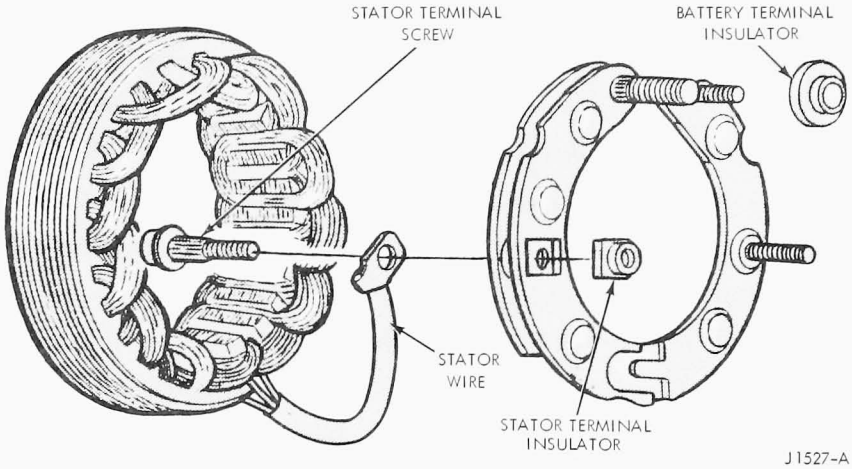

FIG. 13 Stator and Rectifier Assembly—61-Ampere Alternator

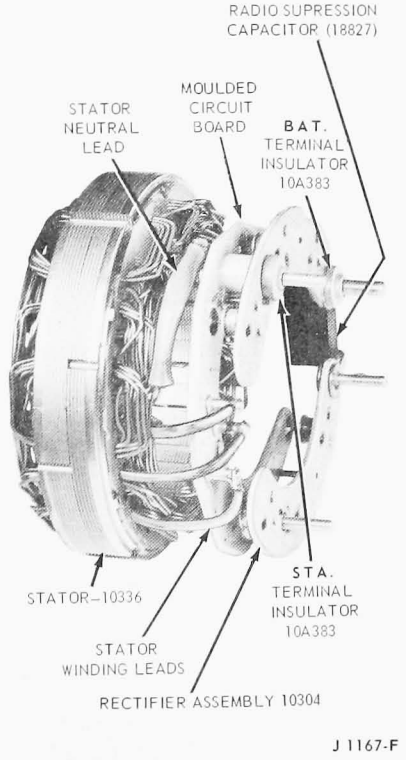

FIG. 12 Stator Lead Connections—Except 61-Ampere Alternator

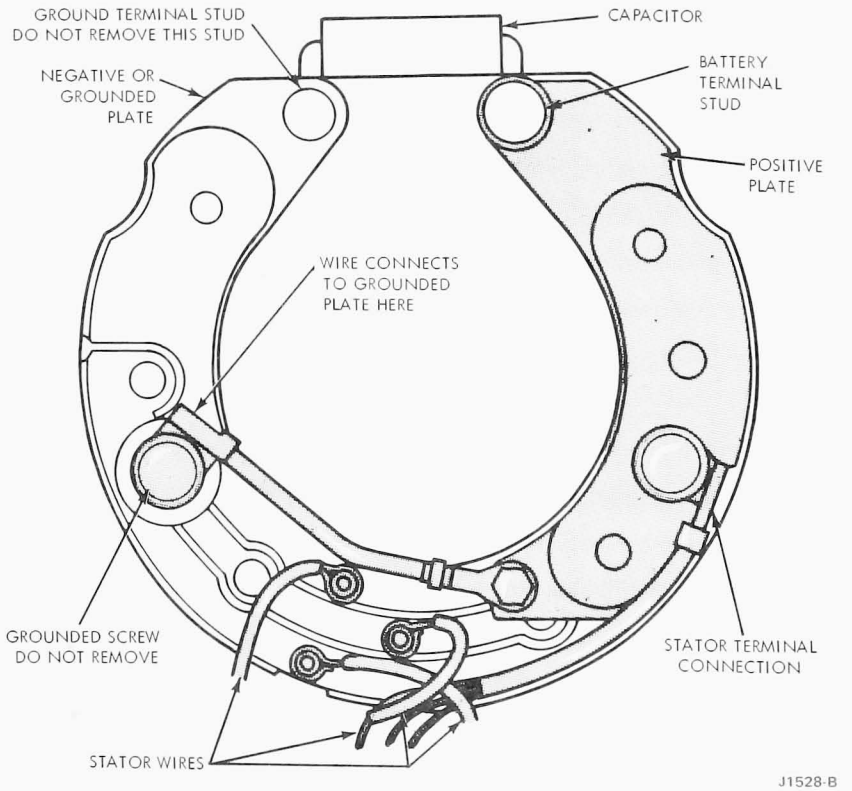

FIG. 14 Rectifier Terminal Locations—61-Ampere Alternator

b. Rotate the terminal screw until it locks in position. Then, press the screw in finger tight.
c. Position the stator wire as shown in Fig. 14. Then, press the terminal screw into the rectifier and insulator as shown in Fig. 15.

12. Position the radio noise suppression capacitor on the rectifier terminals. On the circuit board with exposed diodes, install the STA and BAT terminal insulators (Fig. 12). On the single circuit board, position the square stator-terminal insulator in the square hole in the rectifier assembly (Fig. 7). Position tthe BAT terminal insulator (Fig. 16) on the BAT terminal.

Position the stator and rectifier assembly in the rear housing. Make certain that all terminal insulators are seated properly in their recesses (Fig. 16). Position the STA (black), BAT (red), and FLD (orange) insulators, on the terminal bolts, and install the retaining nuts (Fig. 17).

13. Wipe the rear end bearing surface of the rotor shaft with a clean lint-free rag.
14. Position the rear housing and stator assembly over the rotor and align the scribe marks made during disassembly. Seat the machined portion of the stator core into the step in both end housings. Install the housing through bolts. Remove the brush retracting wire, and put a daub of water-proof cement over the hole to seal it.

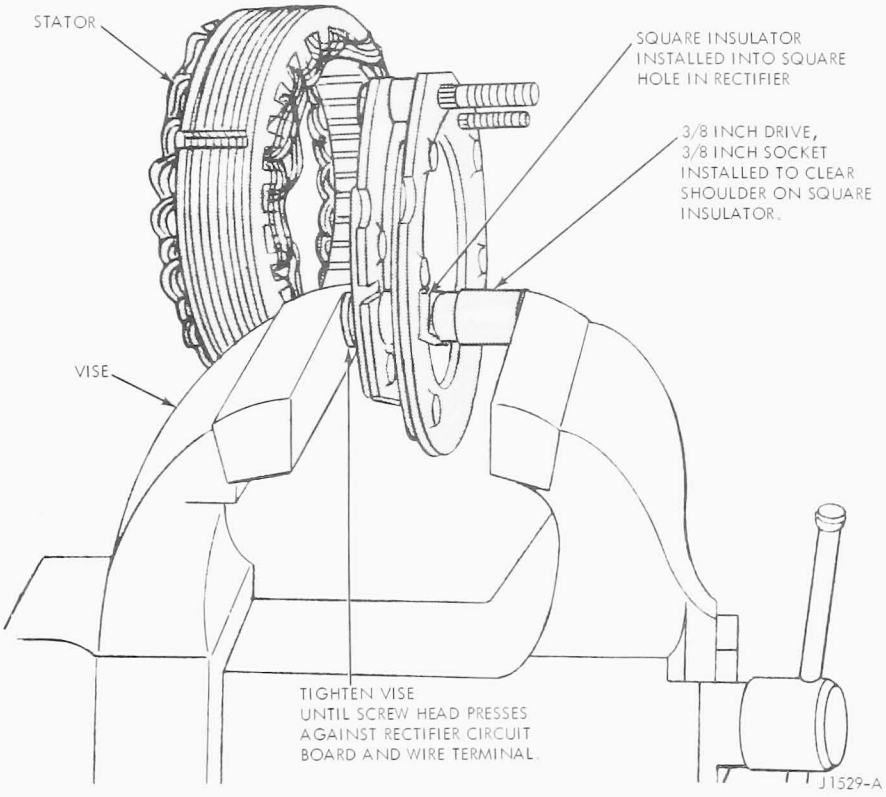

FIG. 15 Stator Terminal Screw Installation—61-Ampere Alternator

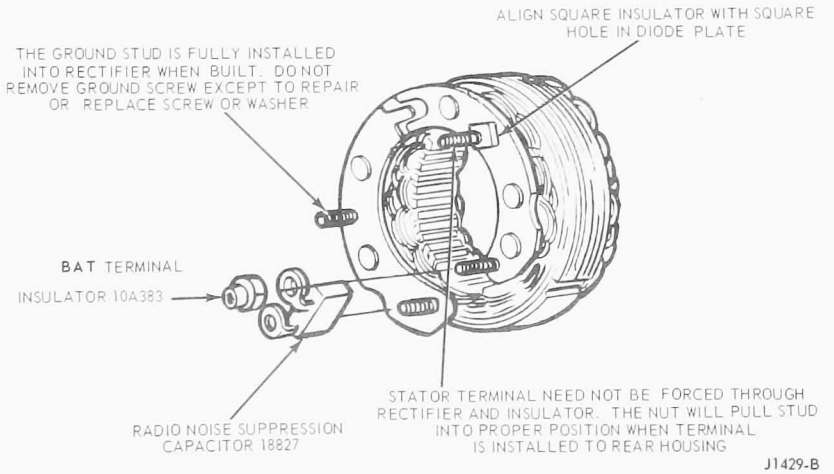

FIG. 16 Terminal Insulators—Fiber-Glass Circuit Board

70 AND 90-AMPERE G.P.D. REAR TERMINAL ALTERNATOR

Disassembly

Figure 18 shows a disassembled view of the G.P.D. rear terminal 70-ampere alternator.

1. Remove the brush holder and cover assembly from the rear end housing.
2. Mark both end housings and the stator with a scribe mark for assembly.
3. Remove the three housing through bolts.
4. Separate the front housing and rotor from the stator and rear housing.
5. Remove the drive pulley nut, lock washer, flat washer, pulley, fan, fan spacer and rotor from the front housing (Fig. 9).
6. Remove the three screws that hold the front bearing retainer, and remove the retainer. If the bearing is damaged or has lost its lubricant, support the housing close to the bearing boss, and press out the bearing from the housing.
7. Remove all the nut and washer assemblies and insulators from the rear housing, and remove the rear

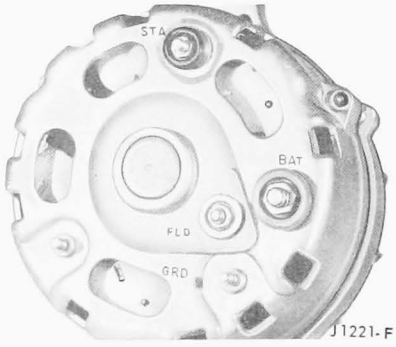

FIG. 17 Alternator Terminal Locations

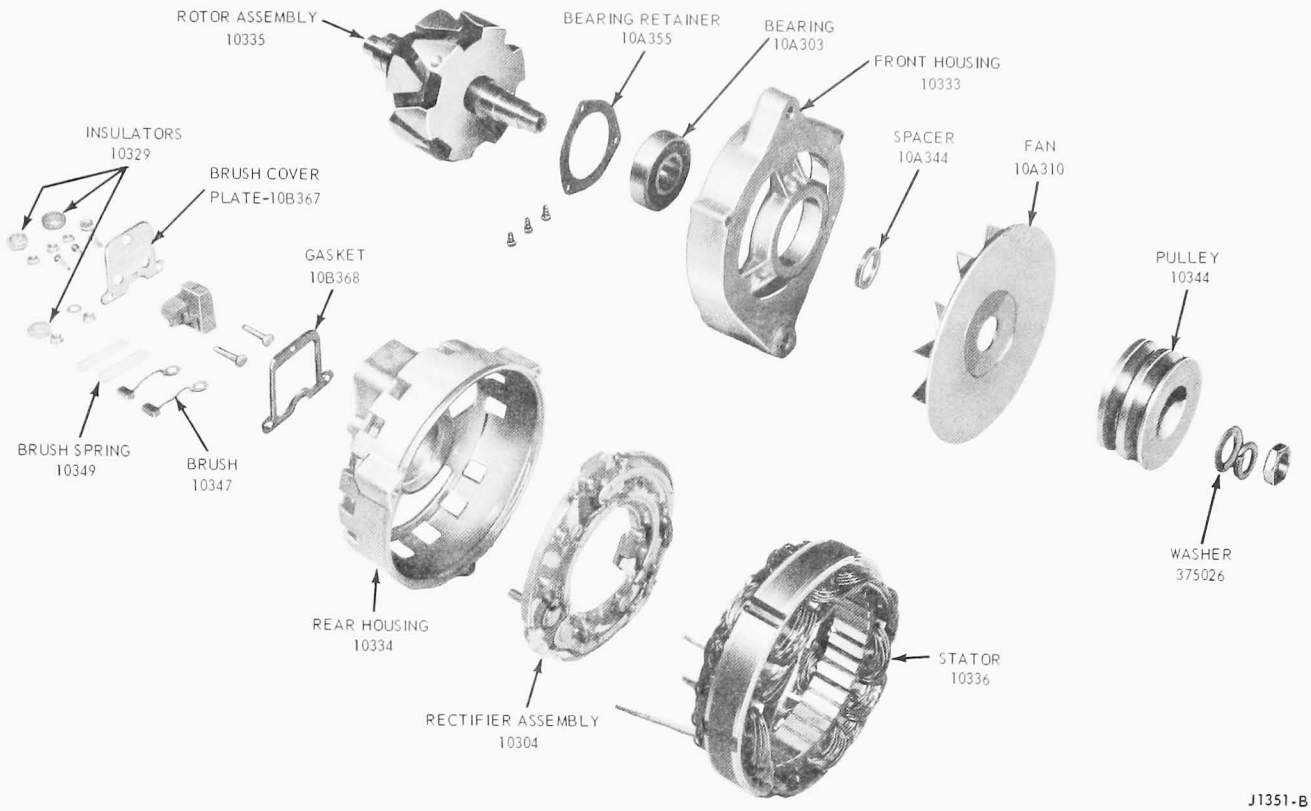

FIG. 18 Disassembled 70-Ampere Alternator—Typical of 90-Ampere Alternator

housing from the stator and rectifier assembly.

8. If replacement is necessary, press the bearing from the rear housing, supporting the housing on the inner boss.
9. Unsolder the stator leads from the rectifier assembly, and separate the stator from the assembly. Use a 200 watt soldering iron.
10. Perform a diode test and an open and grounded stator coil test.

Assembly

1. If the front bearing is being replaced, press the new bearing in the bearing boss putting pressure on the outer race only. Then, install the bearing retainer and tighten the retainer screws until the tips of the retainer touch the housing.
2. Position the rectifier assembly to the stator, wrap the stator leads around the rectifier terminals and solder them (Fig. 19 or 20). Use a 200 watt soldering iron.
3. If the rear housing bearing was removed, press in a new bearing from the inside of the housing until the bearing is flush with the outer end surface. Put pressure on the bearing outer race only.
4. Install the BAT-GRD insulator (Fig. 19 or 20). Position the stator and rectifier assembly in the rear end housing.
5. Install the STA (purple) and BAT (red) terminal insulators on the terminal bolts and install the nut and washer assemblies. **Make certain that the shoulders on all insulators, both inside and outside of the housing, are seated properly before tightening the nuts.**
6. Position the front housing over the rotor and install the fan spacer, fan, pulley, flat and lock washers and nut on the rotor shaft (Fig. 18).
7. Wipe the rear end bearing surface of the rotor shaft with a clean lint free rag.
8. Position the rotor with the front housing into the stator and rear housing assembly, and align the scribe marks made during disassembly. Seat the machined portion of the stator core into the step in both housings, and install the through bolts.
9. Hold the brushes in position by inserting a stiff wire in the brush

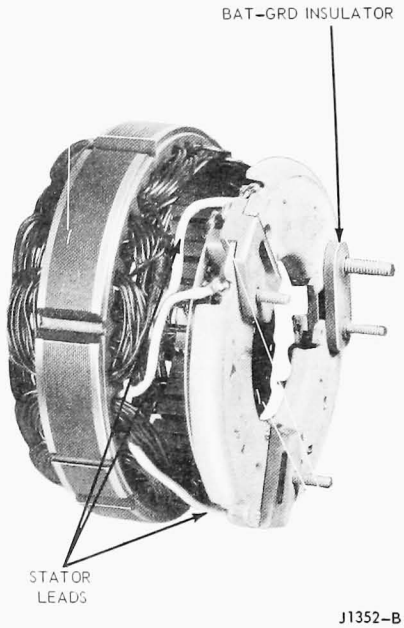

FIG. 19 Stator Lead Connections—70-Ampere Alternator

holder (Fig. 21).

10. Position the brush holder and cover assembly to the rear housing and install the three mounting screws. Remove the brush retracting wire and put a daub of water-proof cement over the hole to seal it.

BRUSH REPLACEMENT

1. Remove the brush holder and cover assembly from the rear housing.
2. Remove the terminal bolts from the brush holder and cover assembly, and remove the brush assemblies.
3. Position the new brush terminals on the terminal bolts and assemble the terminals, bolts, brush holder washers and nuts (Fig. 21). The insulating washer mounts under the FLD terminal nut. The entire brush and cover assembly is also available for service.
4. Depress the brush springs in the brush holder cavities and insert the brushes on top of the springs. Hold the brushes in position by inserting a stiff wire in the brush holder as shown in Fig. 21. Position the brush leads as shown in Fig. 21.
5. Install the brush holder and cover assembly to the rear housing. Remove the brush retracting wire and put a daub of water-proof cement over the hole to seal it.

PART 31-21 Leece-Neville Alternators

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS	21-01	REMOVAL AND INSTALLATION	21-02
DESCRIPTION AND OPERATION	21-01	SPECIFICATIONS	21-03
DISASSEMBLY AND OVERHAUL	21-02	TESTING	21-01

DESCRIPTION AND OPERATION

70 and 105-AMPERE ALTERNATORS

The operation and general electrical description of the 70 and 105-ampere Leece Neville alternators is similar to that for the G.P.D. alternator (Part 31-10). The field brushes of the Leece Neville alternators are mounted in a sealed brush holder on the brush housing (Fig. 4). Two sealed ball bearings support the rotor in both end housings.

TESTING

Refer to Wiring Diagram Manual, Form 7795P-73 for schematics and locations of wiring harnesses. **Use care when connecting any test equipment to the alternator system, as the alternator output terminal is connected to the battery at all times. Refer to Part 31-01 for charging system test procedure.**

ADJUSTMENTS

BELT ADJUSTMENT

1. Check the belt tension with Tool T63L-8620-A. The belt should be within specifications (Specifications Section at end of this Part).
2. If the belt is not adjusted within specifications, loosen the alternator mounting bolt to a snug position and loosen the adjusting arm bolts.
3. **Apply pressure on the alternator front housing to increase the belt tension** and tighten the adjusting arm to alternator bolt.
4. Recheck the belt tension with tool T63L-8620-A. Readjust the belt to the specified tension if necessary.
5. Tighten all mounting bolts

REMOVAL AND INSTALLATION

ALTERNATOR REPLACEMENT

1. Disconnect the battery ground cable.
2. Loosen the mounting bolts and the adjusting arm to alternator bolt, and remove the drive belt.
3. Remove the mounting bolts and the adjusting arm bolt, disconnect the alternator wires and remove the alternator.
4. Position the alternator to the mounting bracket and install the mounting bolts and adjusting bracket bolt finger tight. Connect the wires to the alternator (Fig. 1).
5. Adjust the belt tension with tool T63L-8620-A. Tighten the mounting bolts to 22-32 ft-lb torque, and check the operation of the alternator.

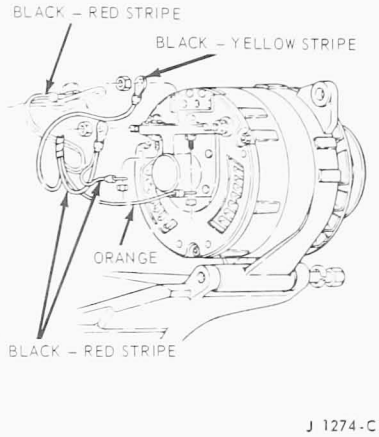

FIG. 1 Typical Leece Neville Alternator Wiring Connections

DISASSEMBLY AND OVERHAUL

A disassembled view of the alternator is shown in Fig. 2.

DISASSEMBLY

1. Remove the pulley nut. Then, remove the pulley with a gear puller, and remove the shaft key and spacer.
2. Remove the brushes and terminal insulator, and remove the brush holder assembly from the housing.
3. Remove the through bolts and separate the brush end housing and stator assembly from the alternator.
4. Remove the nuts from the three AC terminals. Remove the stator from the end housing.
5. If the front bearing is damaged and must be replaced, remove the rotor from the drive-end housing using a gear puller or an arbor press. Then, remove the bearing retainer from the drive-end housing and press out the old bearing from the housing.
6. If the rear bearing is worn or damaged and must be replaced, unsolder the field leads from the slip rings, and remove the slip rings and the bearing from the slip ring end of the rotor shaft. Use a gear puller. **Use care in removing the slip rings, so as not to damage them. If they are cracked or broken during disassembly, they must be replaced.**
7. Remove the rectifier assembly mounting bolts, terminals, and insulators and remove the rectifier assemblies. Remove the stator terminal insulator.

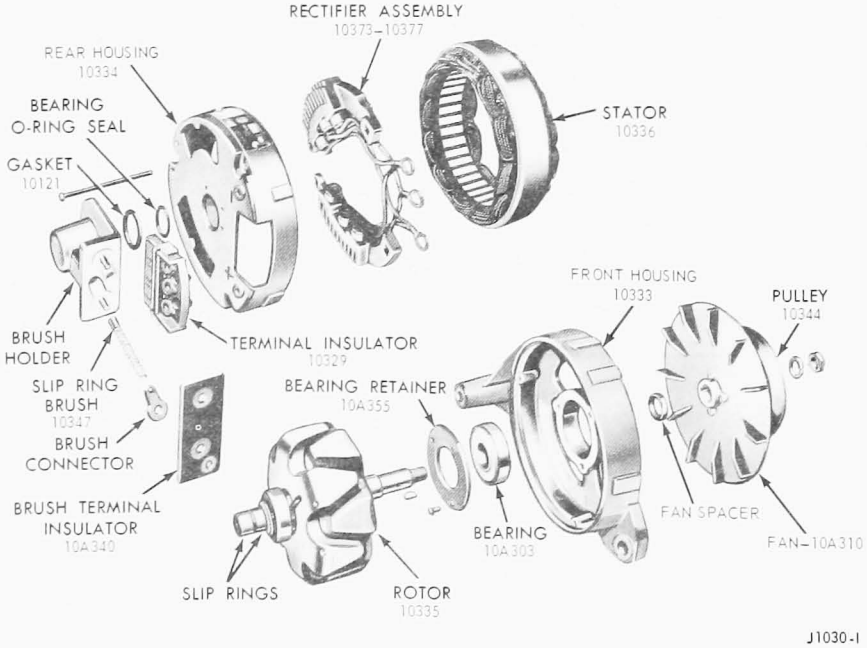

FIG. 2 Disassembled 70 and 105-Ampere Leece Neville Alternator

PARTS REPAIR OR REPLACEMENT

Nicks and scratches may be removed from the rotor slip rings by turning down the slip rings. Remove only enough to clean up the surface. If the slip rings are badly damaged, they should be replaced.

ASSEMBLY

1. Press the new bearing onto the slip-ring end of the rotor shaft. **Put**

pressure on the bearing inner race only. Heat the slip rings so that the insulation will not split, carefully press the slip rings on the shaft and solder the field wires to the rings.

2. Press the new bearing into the drive end housing, and install the bearing retainer. **Put pressure on the outer race only.**
3. Place the slip-ring end of the shaft firmly on a flat plate in an Arbor Press, and assemble the drive end housing and bearing on to the drive end of the shaft. **Use a tube or pipe so as to put pressure on the bearing inner race only.**
4. Install the stator insulator. Put the rectifier insulators in position. Place the rectifier assemblies in the housing and install the mounting screws and terminals. Make certain that the rectifier assemblies are insulated from the end frame. Position the three rectifier terminals to the terminal studs. Position the wires under the tabs extending from each heat sink to prevent interference with the rotor (Fig. 3).
5. Place the stator in position (Fig. 3), and line up the end-housing through-bolt holes to match those in the stator. Position the three stator terminals over the three rectifier terminals, and install the terminal nuts (Fig. 3).

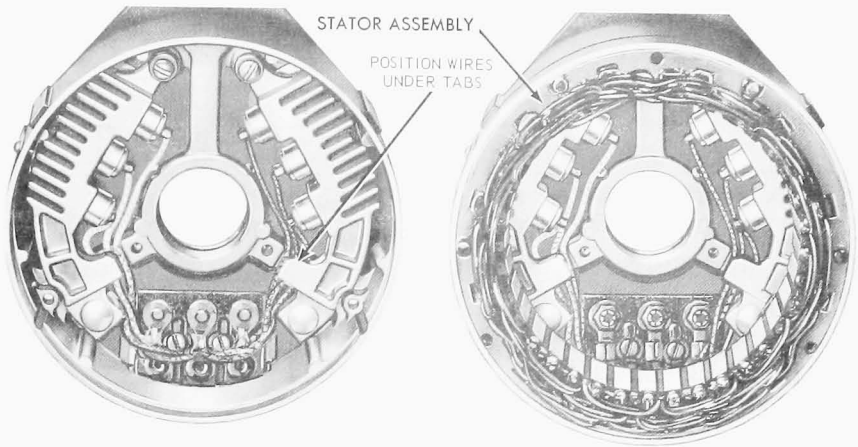

FIG. 3 Slip-Ring End Housing, Rectifier and Stator Assembly

6. Place the brush end housing and stator assembly into position over the rotor. Use the housing through bolts to line up the two housings and the stator. Tighten the housing through bolts.
7. Install the brush holder with the O-ring between the holder and the frame (Fig. 2). Place the brushes and springs in the holder with the extruded portion of the brush connectors against the terminal screw shoulders. Hold the brush connectors in position with a machinists steel scale until the terminal insulator is installed. Install the brush terminal insulator, and withdraw the steel scale.
8. Install the fan spacer, shaft key, fan, pulley, and lock washer and nut. Tighten the mounting nut to 40 ft-lbs torque.

CJ1461-C

PART 31-40 Alternator Electro-Mechanical Regulator

This Information Applies To: All 38, 42, 55 and 61 Ampere Alternator Regulators

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS	40-02	REMOVAL AND INSTALLATION	40-02
DESCRIPTION AND OPERATION	40-01	TESTING	40-01

DESCRIPTION AND OPERATION

ELECTRO-MECHANICAL REGULATOR

The alternator regulator has been designed to exercise automatic control over the charging system, and also to compensate for seasonal temperature changes. The electro-mechanical regulator is factory calibrated and is not to be adjusted.

The alternator regulator is composed of two control units, a field relay and a voltage limiter, mounted as an assembly (Fig. 1). Refer to Wiring Diagram Manual, Form 7795P-73, for schematics and locations of wiring harnesses. Figs. 1 and 2, Part 31-10 show schematics of the electro-mechanical voltage regulator system.

FIELD RELAY

The field relay serves to connect the charging system voltage to the field circuit when the engine is running.

CHARGE INDICATOR CIRCUIT—LIGHT

When the ignition switch is closed, the charge indicator light, shunted with a 15-ohm resistor, allows adequate starting field current.

When the alternator builds up enough voltage to close the field relay contacts, full voltage is applied to the field, and the charge indicator light goes out.

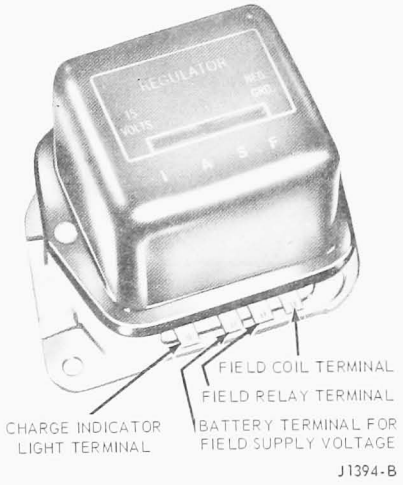

FIG. 1 Alternator Electro-Mechanical Regulator

CHARGE INDICATOR CIRCUIT—AMMETER

When the ignition switch is closed, the field relay is energized. Closing the relay contacts connects the battery and alternator output to the field through the voltage limiter contacts.

VOLTAGE LIMITER

The temperature compensated voltage limiter is a double contact unit. Voltage limiting is accomplished by controlling the amount of current supplied to the rotating field.

TESTING

Refer to the Ford Car and Truck Diagnosis Manual for regulator diagnosis procedures.

Use the Rotunda ARE 20-22 tester or the Rotunda ARE 27-38 tester to test the electro-mechanical regulator. Use the Rotunda ARE 27-38 tester or a voltmeter for the following tests.

VOLTAGE REGULATOR CALIBRATION TEST

The alternator belt tension must be adjusted within specification, and the charging system electrical connections must be clean and tight before testing the regulator.

TEST PROCEDURE

Connect the voltmeter positive lead to the battery positive terminal, and the negative lead to the battery negative terminal. **Turn off all electrical loads.** Then, check and record the voltmeter reading. Connect the red lead of a tachometer to the distributor terminal of the coil and the black tachometer lead to a good ground.

Place the transmission shift lever in the neutral or park position and start the engine. Increase the engine speed to 1800-2200 rpm for 2 or 3 minutes. Check and record the voltmeter reading. It should be 1 to 2 volts higher than the first reading. This is the regulated voltage reading. If the reading is less than 1 volt or greater than 2 1/2 volts, replace the voltage regulator. If the reading is between 1 and 2 volts, turn on the headlights and heater blower. The voltage should not decrease more than 1/2 volt from the regulated voltage reading. Replace the regulator if the voltage drop is greater than 1/2 volt below the regulated voltage.

ADJUSTMENTS

ELECTRO-MECHANICAL REGULATOR

The electro-mechanical regulator is factory calibrated and sealed and is not to be adjusted. If the regulator does not operate as specified in the Voltage Regulator Calibration Test, it must be replaced.

REMOVAL AND INSTALLATION

ALTERNATOR REGULATOR

1. Disconnect the battery ground cable.
2. Remove the regulator mounting screws.
3. Disconnect the regulator from the wiring harness.
4. Connect the new regulator to the wiring harness.
5. Mount the regulator to the regulator mounting plate. The radio suppression condenser bracket mounts under one mounting screw. The ground lead mounts under the other mounting screw.
6. Connect the battery ground cable, and test the system for proper voltage regulation.

PART 31-41 Alternator Transistorized Regulator

This Information Applies To: All 70, 90 and 105-Ampere Alternator Regulators

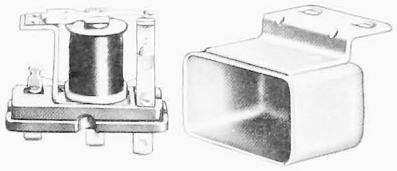
COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS	41-04	SPECIFICATIONS	41-05
DESCRIPTION AND OPERATION	41-01	TESTING	41-04
REMOVAL AND INSTALLATION	41-05		

DESCRIPTION AND OPERATION

ALTERNATOR TRANSISTORIZED REGULATOR

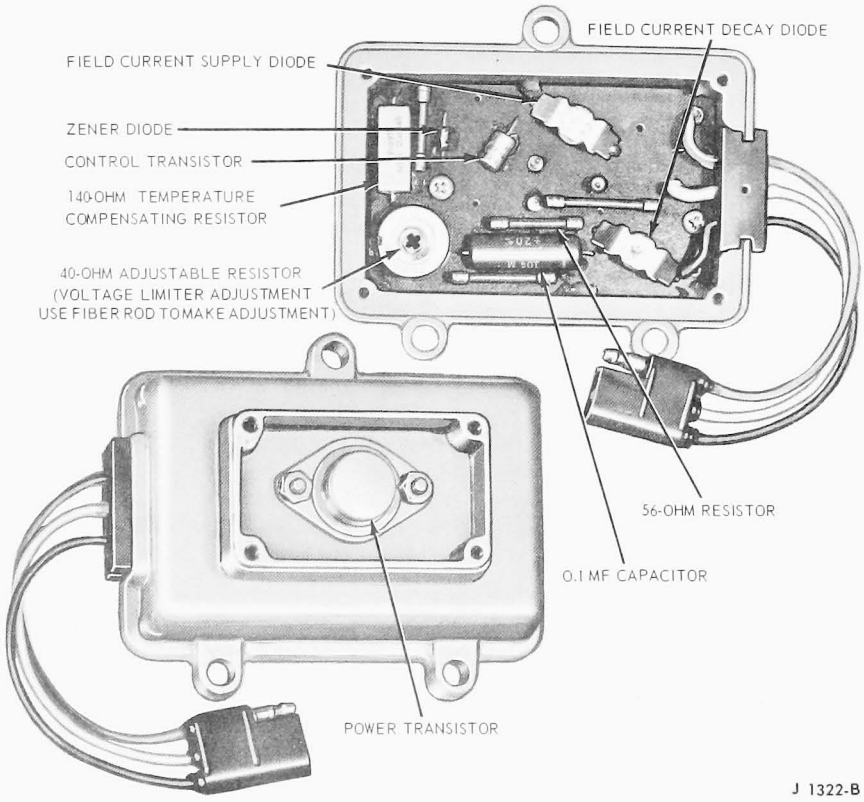
The transistorized voltage regulator (Fig. 1), controls the alternator voltage output in a similar manner to an electro-mechanical voltage regulator, by regulating the alternator field current. The regulation is accomplished electronically with the use of transistors and diodes rather than by a vibrating armature relay. The voltage sensing element is a zener diode which has the characteristic of suddenly changing its resistance when a specified voltage is reached. The field relay (Fig. 2) is still used, but it is mounted separately from the voltage regulator.

Figs. 3 and 4 show schematics of the transistorized voltage regulator system.



J 1323-A

FIG. 2 Field Relay—Transistorized Regulator



J 1322-B

FIG. 1 Transistorized Voltage Regulator

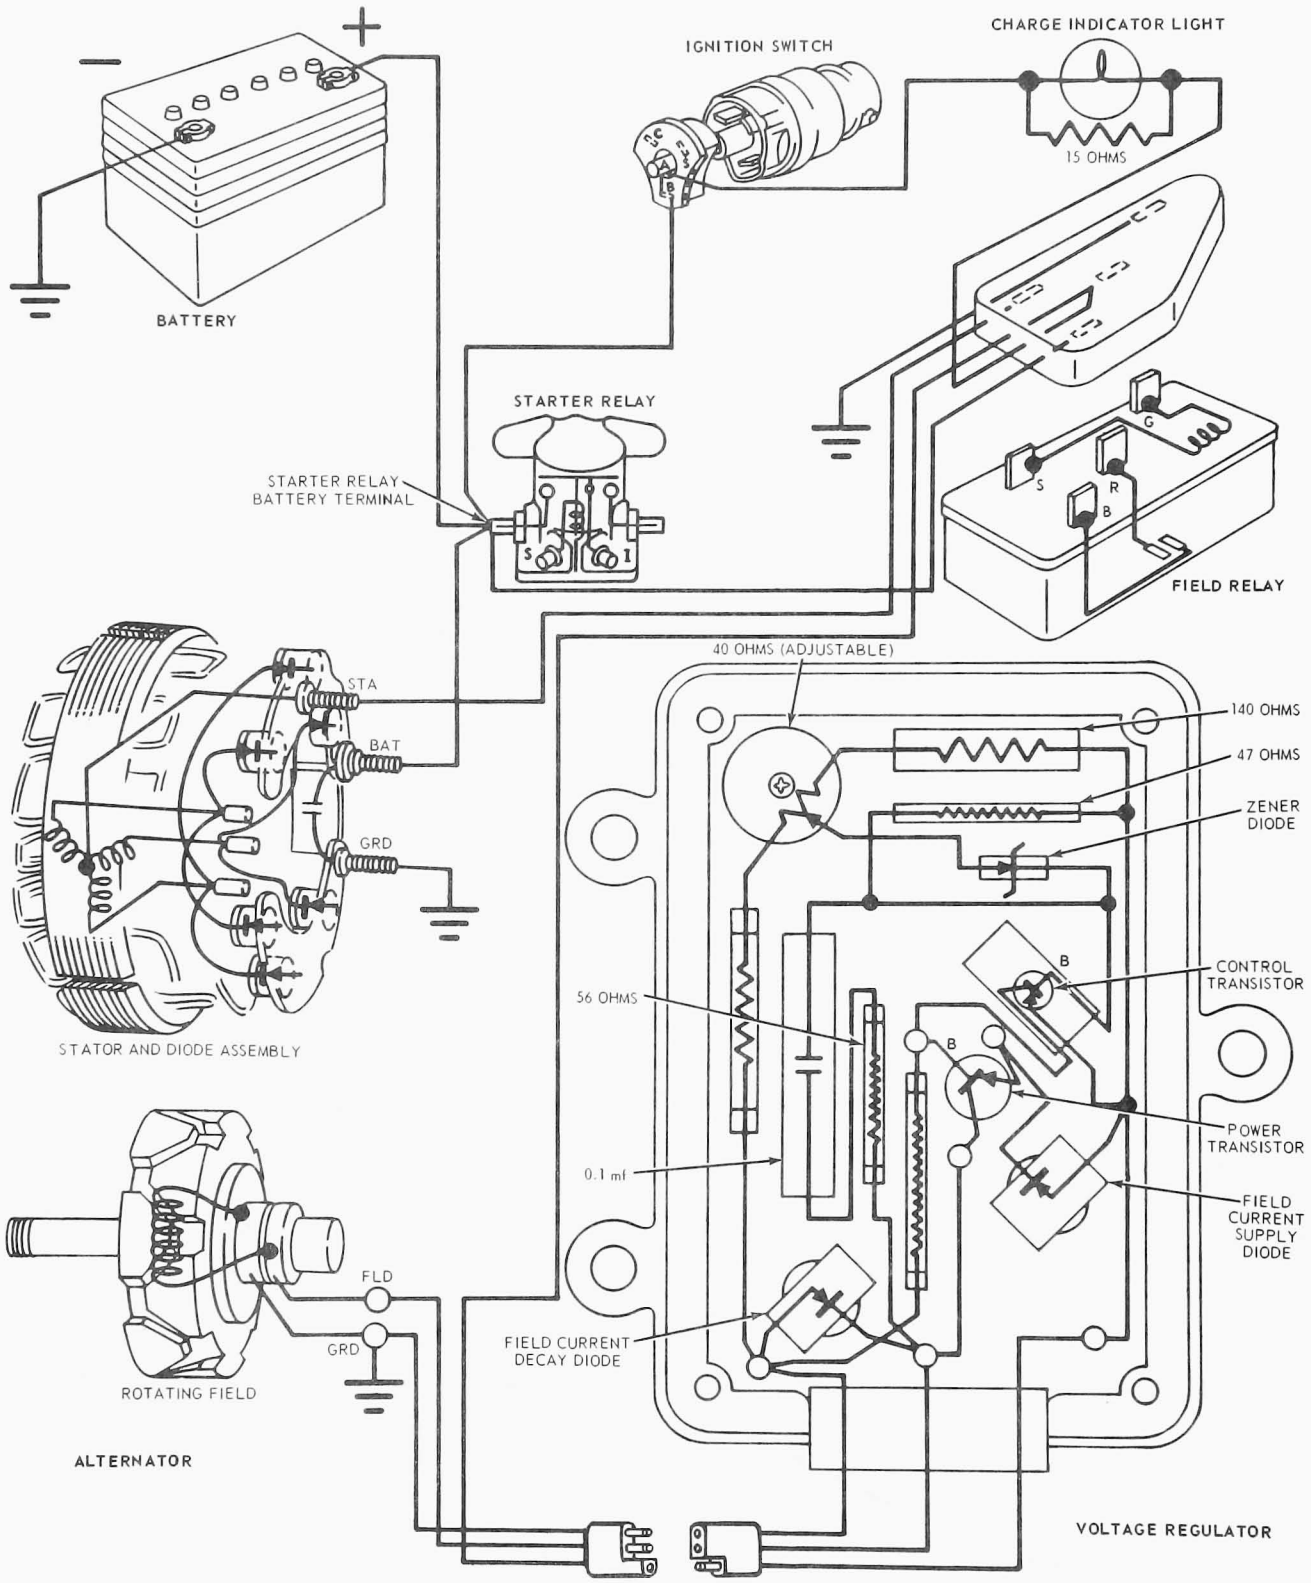


FIG. 3 Alternator System with Transistorized Voltage Regulator and Charge Indicator Light

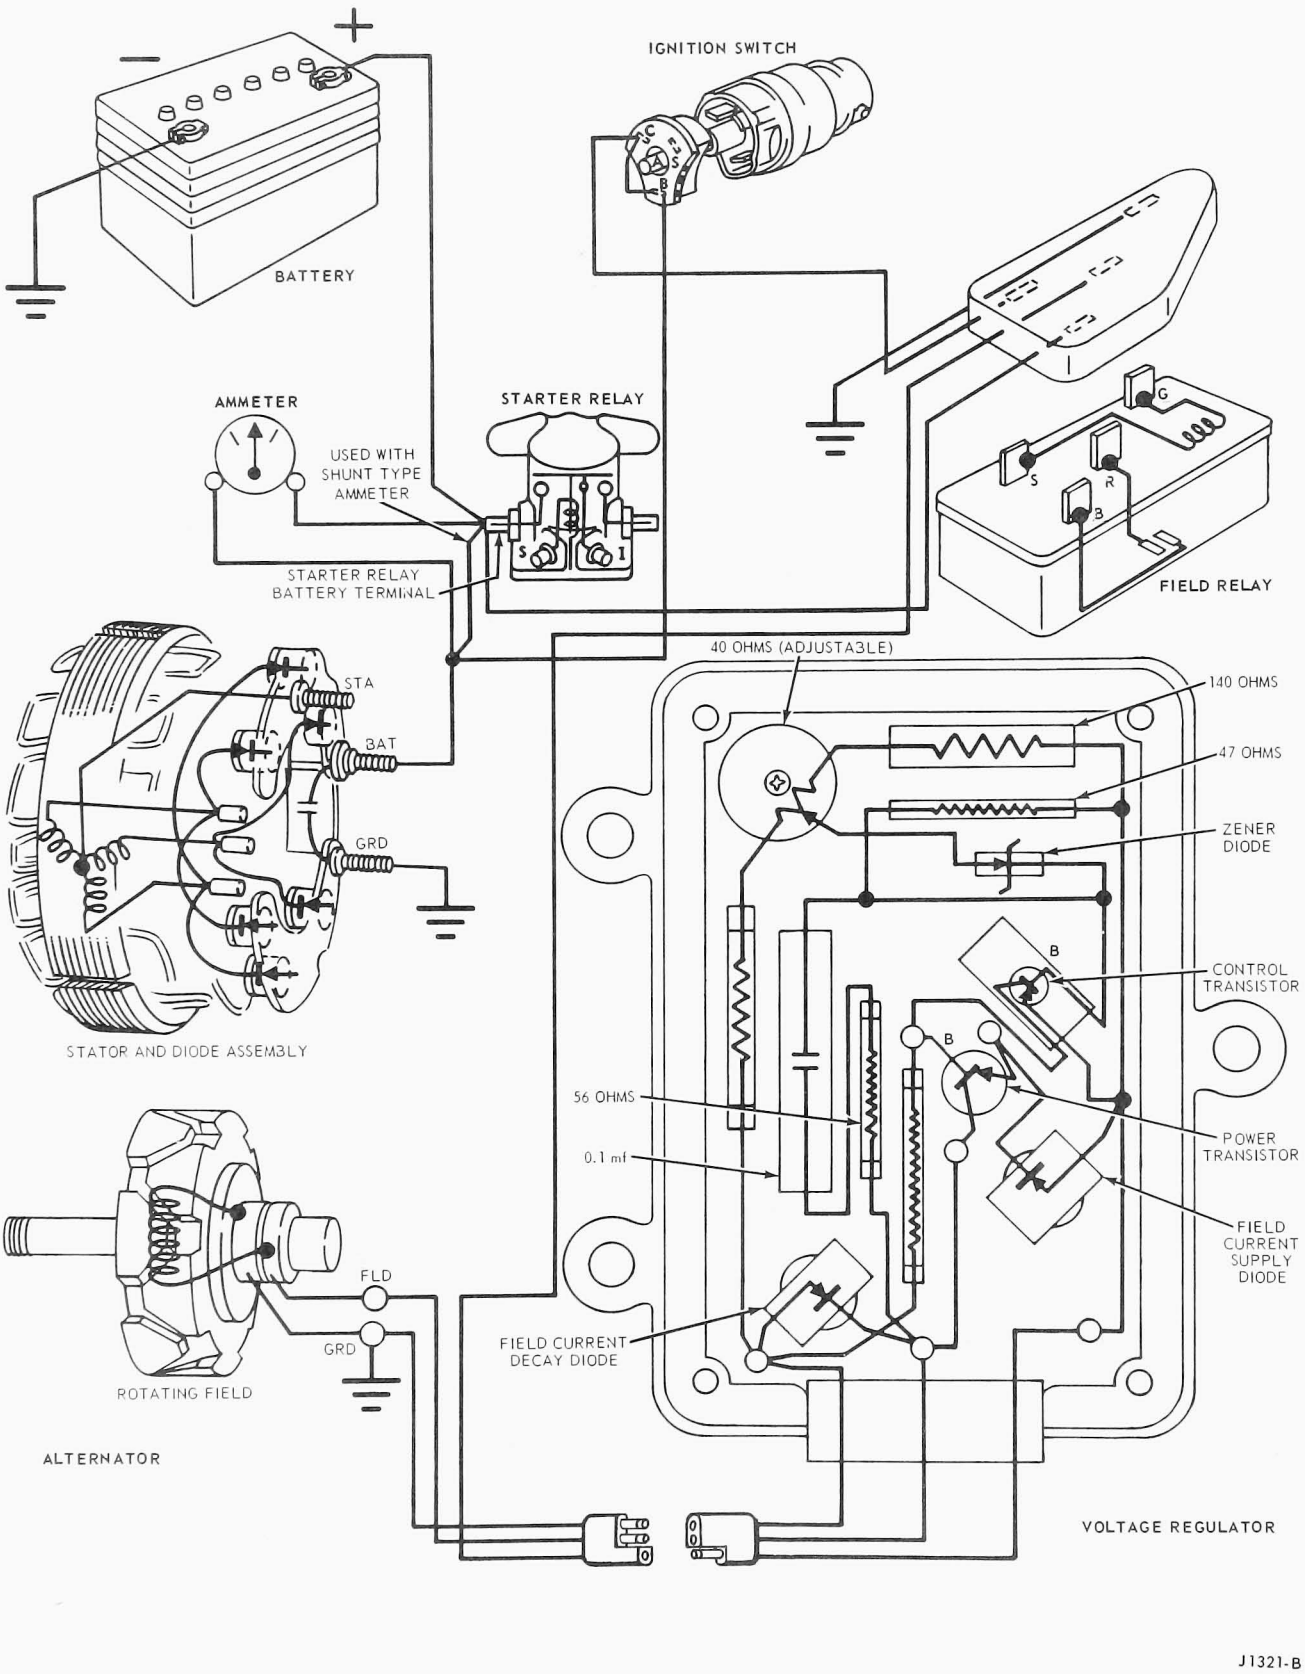

FIG. 4 Alternator System with Transistorized Voltage Regulator and Ammeter

TESTING

ALTERNATOR TRANSISTORIZED REGULATOR

Use only the Rotunda ARE 27-38 tester for transistorized regulator testing.

VOLTAGE LIMITER TEST

Voltage limiter calibration tests must be made with the regulator operating with battery and ignition loads only.

For accurate voltage limiter testing, the battery specific gravity must be at least 1.230. **If the battery is low in charge, either charge it to 1.230 specific gravity or substitute a fully charged battery before making a voltage limiter test. See Part 31-01.**

To test the transistorized voltage regulator on the vehicle, make the test connections to the battery and tester knob adjustments as shown in Fig. 5.

1. Place the transmission in neutral or park **and apply the parking brake.**
2. Close the battery adapter switch and start the engine. Make sure that all lights and electrical accessories are off. Open the battery adapter switch.
3. Operate the engine at approximately 2000 rpm for 5 minutes. (Use a tachometer).
4. Read the voltmeter on the tester. If the voltage is within specification (Specifications Section at end of this Part), the voltage regulator and alternator are functioning normally.

FIELD RELAY TEST

Disconnect the relay connector plug. Make the connections as shown in Fig. 6. Slowly rotate the field rheostat control clockwise from the maximum counterclockwise position until the test light comes on. Observe the voltmeter reading at the moment that the light comes on. This is the relay closing voltage. If the relay closes immediately, even with the field rheostat close to the maximum counterclockwise position, depress the red button between the two meters, and repeat the test. If the closing voltage is not to specification (Specifications Section at end of this Part), replace the relay.

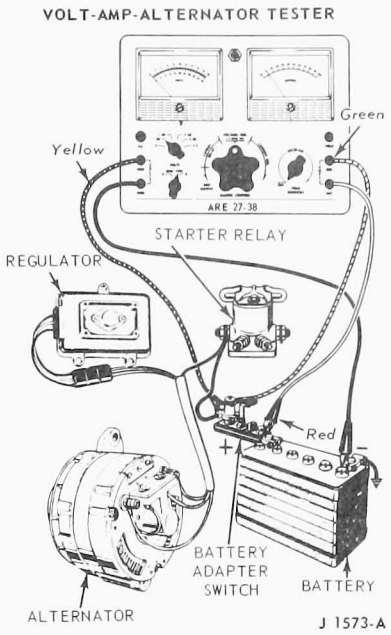

FIG. 5 Transistorized Regulator Voltage Limiter Test

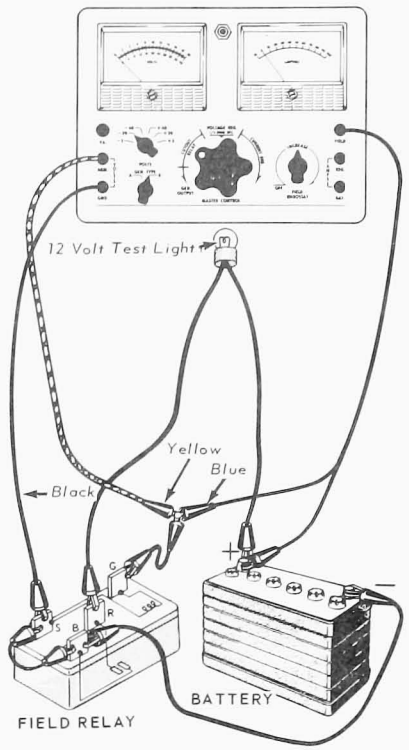

FIG. 6 Transistorized Regulator Field Relay Test

ADJUSTMENTS

TRANSISTORIZED REGULATOR

The only adjustment on the transistorized alternator regulator is the voltage limiter adjustment.

Adjustment of the transistorized voltage regulator must be made with the regulator at normal operating temperature. Remove the regulator mounting screws and remove the bottom cover from the regulator. The voltage setting may be moved up or down by adjusting the 40-ohm adjustable resistor (Fig. 1). Use a fiber rod as a screwdriver for this adjustment.

Follow the test procedure as outlined under Voltage Limiter Test (Testing in this Part), when making this adjustment.

REMOVAL AND INSTALLATION

ALTERNATOR TRANSISTORIZED REGULATOR

1. Remove the battery ground cable.
2. Remove the regulator mounting screws.
3. Disconnect the regulator from the wiring harness.
4. Connect the new regulator to the wiring harness.
5. Mount the regulator. The ground lead mounts under one of the mounting screws.
6. Connect the battery ground cable, and test the system for proper voltage regulation.

PART 32-01 Lighting System General Service

Before performing any Lighting System tests, be sure the battery is in a fully charged condition and all battery cable connections are clean and tight.

A visual inspection is an important part of the Lighting System test. Check for wires with frayed or damaged insulation, loose connections and proper harness routing.

Any problems found by the visual inspection should be corrected before performing further tests of the Lighting System.

Headlight Switch	03-02

DESCRIPTION AND OPERATION

HEADLIGHTS

Two No. 2 type headlights are used. The lights have two filaments each, one for low beam and one for high beam, and are identified by the numeral 2 molded in the glass lens. Headlights are controlled by the headlight switch on the instrument panel and the foot-operated dimmer switch on the floorboard to the left of the clutch pedal.

HEADLIGHT SWITCH

The headlight switch (Fig. 1) is a combination three-position switch that controls the circuits to the headlights, exterior lights (except stop lights and turn signal/hazard warning lights), instrument panel lights and other interior lights. The switch shown in Fig. 1 is used on C-L500-750, F-100-350, Bronco, Econoline and W-Series. Circuits are connected to the switch by a molded multiconnector. Two circuit breakers are located in the switch: one protects the headlight circuit; the other protects the exterior light circuit as well as the horn circuit.

The interior light circuit is routed through a rheostat on the switch, which is controlled by rotating the switch control knob. This circuit is protected by a fuse in the fuse panel. The switch used on F-B-C-L 500-1100 incorporates one circuit breaker for the headlights. A 25 amp circuit breaker for auxilliary lamps is mounted in the fuse panel for L-Series and to the fuse panel mounting screw for F-B and C Series.

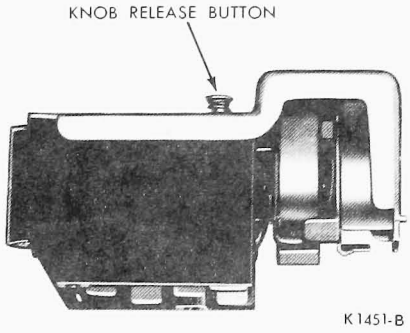

FIG. 1 Headlight Switch—C, L-500-750 and W-Series

ADJUSTMENTS

HEADLIGHT AIM

Before making any headlight adjustments, perform the following preparatory steps:

1. Remove ice or mud from under fenders.
2. See that all tires are inflated to recommended pressures.
3. Check car springs for sag or broken leaves.
4. Take into consideration faulty wheel alignment or improper tracking of the rear axle.
5. See that there is no load in the vehicle other than the driver in the front seat.
6. Check functioning of any **level-ride control.**
7. Clean lenses and aiming pads.
8. Check for bulb burn-out and proper beam switching.
9. See that light output is well towards normal new lamp value.
10. Rock the vehicle sideways.

Headlight aim adjustment should be made with the Rotunda Headlight Aiming Kit—Model TRE 540. Use the latest instructions dated June 1971.

The kit equipment can be calibrated to accommodate a slight slope in the floor, making it usable almost any place in the garage.

Each headlight is adjusted by means of two screws located under the headlight trim ring as shown in Fig. 2.

Always bring each beam into final position by turning the adjusting screws clockwise so that the headlight will be held against the tension springs when the operation is completed.

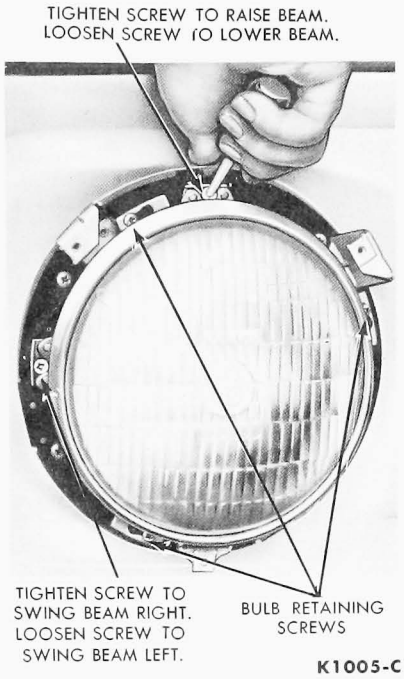

FIG. 2 Headlight Adjustment

REMOVAL AND INSTALLATION

HEADLIGHT BULB

1. Remove the attaching screws and remove the trim ring, or door (Fig. 3).
2. Remove the headlight retaining ring screws (Fig. 2), and remove the retaining ring. **Do not disturb the adjusting screw settings.**
3. Pull the headlight bulb forward and disconnect the wiring assembly plug from the bulb.
4. Connect the wiring assembly plug to the new bulb. Place the bulb in position, making sure that the locating tabs of the bulb are fitted in the positioning slots.
5. Install the headlight retaining ring (Fig. 3).
6. Place the headlight trim ring or door into position, and install the retaining screws.
7. Adjust the headlamp aim using the Rotunda TRE 540 Aimer.

HEADLIGHT SWITCH

1. Disconnect the battery ground cable.
2. Remove the control knob and shaft by pressing the knob release button on the switch housing (Fig. 1), with the knob in the full ON **position. Pull the knob and shaft assembly**

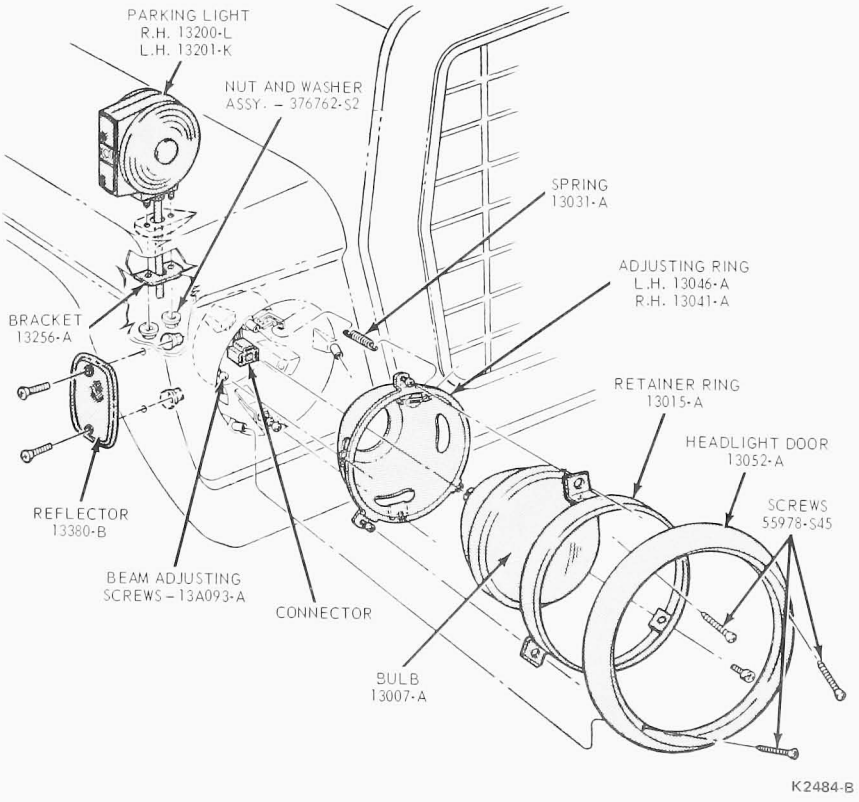

FIG. 3 Headlight and Parking Light—Typical—L Series Shown

out of the switch. Unscrew the mounting nut, remove the bezel and switch, then remove the wiring connector from the switch.

3. To install the switch, connect the wiring connector to the headlight switch, position the switch in the instrument panel, and install the bezel and mounting nut.
4. Install the knob and shaft assembly by inserting it all the way into the switch until a distinct clip is heard. In some instances it may be necessary to rotate the shaft slightly until it engages the switch-contact carrier.
5. Connect the battery ground cable.

DIMMER SWITCH

Lay the floor mat back from the area of the switch, and remove the mounting screws (Fig. 4). Disconnect the wire terminal block from the switch.

Install the switch to the floor, and connect the terminal block to the switch. Replace the floor mat.

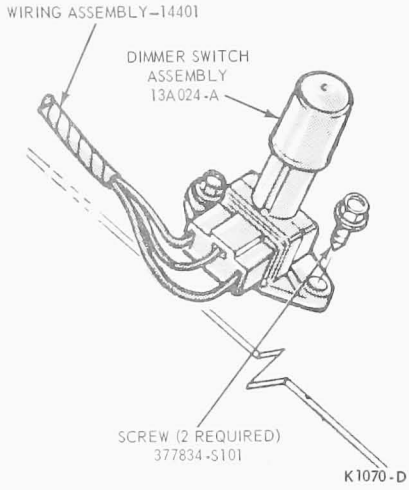

FIG. 4 Headlight Dimmer Switch

PART 32-21 Parking, Rear and Marker Lights

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION		REMOVAL AND INSTALLATION – Cont.	
Stop Light Switch	21-01	Marker Lights	21-04
REMOVAL AND INSTALLATION		Parking Lights	21-03
Back-up Light Switch	21-07	Rear Lights	21-03
License Plate Light	21-06	Stop Light Switch	21-05

DESCRIPTION AND OPERATION

STOP LIGHT SWITCH

ECONOLINE

The Econoline mechanical stop light switch (Fig. 1) is installed in the brake pedal support bracket, just to the left of the brake pedal arm. A tab on the brake pedal arm contacts the switch plunger when the pedal is at rest, pressing the plunger into the switch assembly against the force of the plunger spring. In this position, the stop light electrical circuit is open and the stop lights remain off.

When the pedal is depressed, the tab on the pedal arm moves away from the plunger, allowing it to move outward under the force of the plunger spring. This closes the switch contacts and illuminates the stop lights.

F-100 THROUGH F-350 SERIES

F-100 through F-350 trucks have a mechanical stop light switch (Fig. 2) mounted to the brake pedal arm. When the brake pedal is at rest (brakes not applied), the switch plunger contacts a stationary stop which depresses the plunger. In this position, the switch is open and no voltage is supplied to the stop light. When the pedal is depressed to apply the brakes, the switch moves with the pedal arm away from the stationary stop. This allows the switch plunger spring to extend the plunger and close the switch contacts, illuminating the stop lights.

F AND B-500 THROUGH 7000 SERIES AND BRONCO

The mechanical stop light switch assembly, installed on the pin of the brake pedal arm, straddles the master cylinder push rod, but is not attached directly to the push rod (Fig. 3). The switch assembly moves with the pedal arm when the brake pedal is depressed.

The switch actuating pin is held by spring pressure against the rear end of the push rod. Because of the slight clearance between the eye of the master cylinder push rod and the brake pedal arm pin, the pin and the switch move forward slightly before the push rod moves when the pedal is depressed. This relative movement between the switch and the end of the push rod moves the actuating pin rearward in the switch, closing the switch contacts and completing the circuit to the stop lights.

When the brake pedal is released, the switch moves rearward in relation to the push rod. The spring in the switch returns the actuating pin to its normal position, opening the switch contacts and interrupting the circuit to the stop lights.

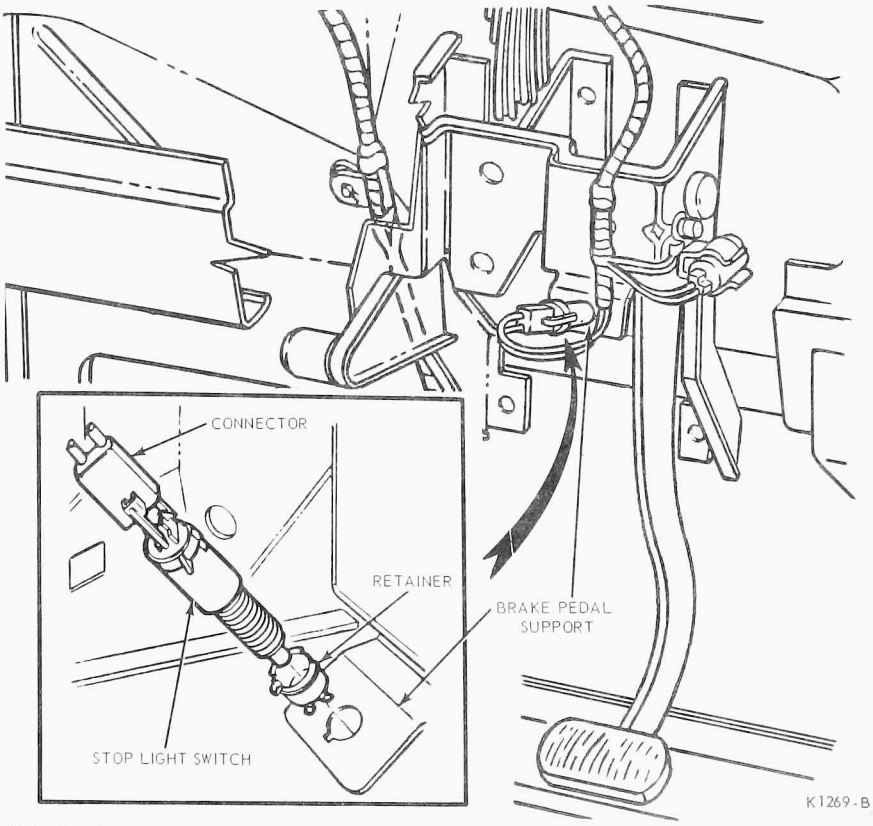

FIG. 1 Stop Light Switch—Econoline

ALL MODELS WITH AIR BRAKES

F-500 through F-750 trucks and school buses with air brakes have an air pressure sensing stop light switch mounted to the air brake control valve on the suspended brake pedal support (Fig. 3).

Tilt-cab trucks with air brakes have an air pressure sensing stop light switch at the air manifold on a frame crossmember under the cab.

On F-700, F-750 and C-Series tractor-trailer air brake systems, an air pressure sensing stop light switch is mounted on a tee-fitting at the double check valve port for the tractor protection valve service line.

The L-Series air brake systems have two stop light switches, one for the service line and one for the emergency line. The switches are threaded into elbow fittings which are, in turn, threaded into pressure ports of the air brake manifold. The manifold is mounted on the engine side of the dash panel.

L-AND C-SERIES WITH HYDRAULIC BRAKES

On L-and C-Series trucks, a pressure sensing stop light switch is mounted on a junction block in the brake hydraulic line. The stop light switch closes the circuit to a relay which, in turn, completes the circuit to the stop lights. The relay is located on the inner side of the dash panel behind the instrument panel.

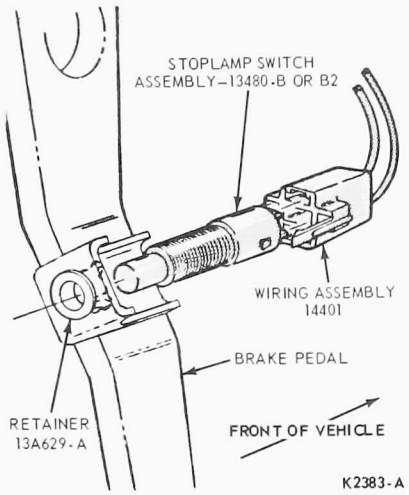

FIG. 2 Stop Light Switch—F-100 through F-350

VACUUM OR AIR OVER HYDRAULIC BRAKES

Tilt-cab and cab-over-engine trucks with vacuum or air assisted hydraulic brakes have a hydraulic pressure sensing stop light switch at the brake line junction block on the frame left side rail.

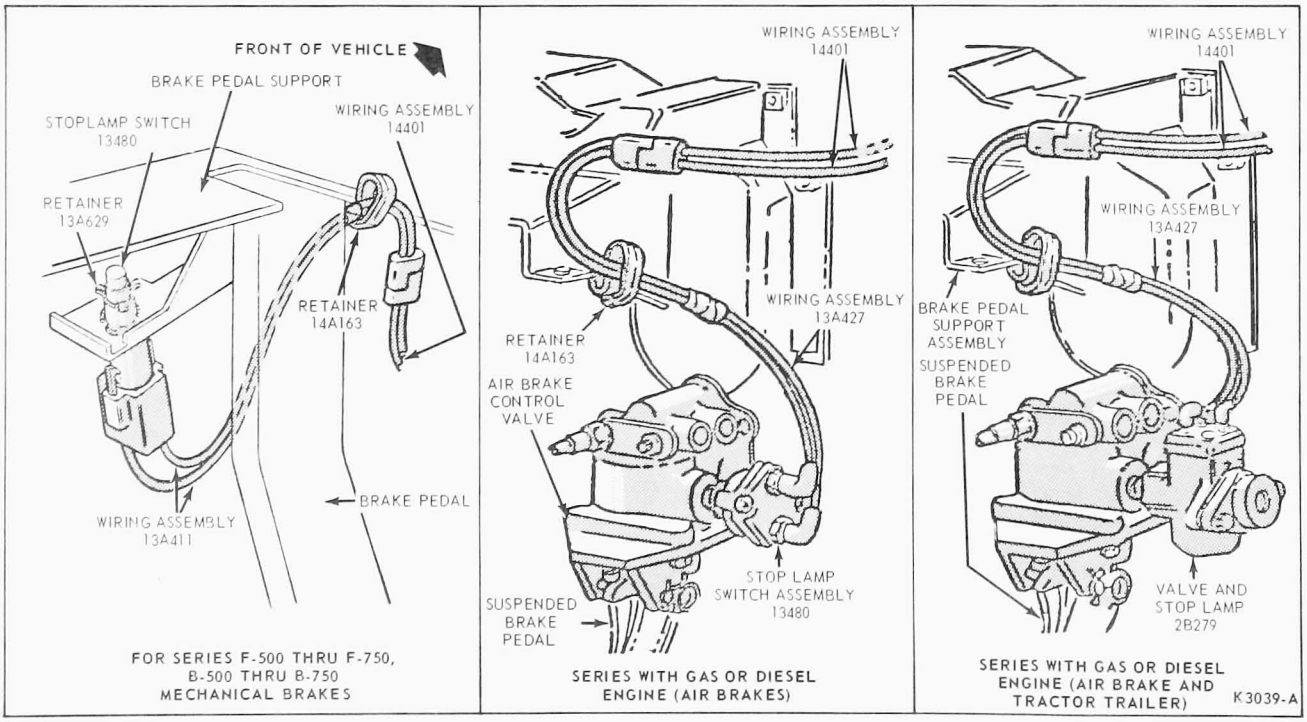

FIG. 3 Stop Light Switch

REMOVAL AND INSTALLATION

PARKING LIGHTS

F-100 THROUGH F-350 SERIES

If light body replacement is required, remove the light assembly by disconnecting the lead wire at the connector plug and removing the mounting nuts. When installing the Econoline or F-100 through 350 light assembly, secure the light ground wire under one mounting nut (Figs. 4 and 5). On the Bronco, secure the ground wire to the grille with a screw. To disassemble the light assembly or to replace a bulb, use the following procedure.

1. Remove the retaining screws and lens.
2. Push in on the bulb and turn it counterclockwise to remove it from the socket. Note the position of the locking pins in the base of the bulb during removal, for reference in installation.
3. Install the new bulb by inserting the bulb with locking pins in the proper position, pressing the bulb inward and rotating it clockwise to lock the bulb in its socket.
4. Hold the lens in position, and install the retaining screws.

500 THROUGH 7000 SERIES

To replace the bulb, remove the four screws and remove the lens from the light body (Fig. 6), press the bulb in and turn clockwise to remove it from the socket. After installing the new bulb, install the lens and retaining screws.

To remove the light body, disconnect the lead wire at the connector plug, remove the mounting nuts from the two mounting studs and withdraw the light and wire assembly from the vehicle (Fig. 6).

On conventional models, the plug connection is in the engine compartment behind the radiator support. The wire will have to be drawn through a grommet in the fender.

On C.O.E. and tilt cab models, the plug connection comes out of a wiring harness on the inner side of the dash panel. The wire will have to be drawn through a grommet in the floor pan.

When installing the light body, locate the reinforcement, the pad and the spacer as shown in Fig. 6.

REAR LIGHTS

F-100 THROUGH F-350 STYLE SIDE PICK-UP, BRONCO AND ECONOLINE

To replace a bulb and/or lens of the combination tail light, stop light and back up light (Figs. 7 and 8), remove the tail light door (if so equipped) and remove the screws that retain the lens to the light body. If replacing the bulb, turn the bulb counterclockwise and remove it from the socket. Install the gasket, lens, and retaining screws. Install the tail light door. The light body can be removed after first removing the door and lens as described above. Remove the light body-to-vehicle retaining screws, withdraw the light body from the vehicle, and disconnect the lead wires at the connectors (Figs. 7 and 8).

F-100 THROUGH F-350 FLARE SIDE PICK-UP

The bulbs in the rear light body can be replaced by removing the lens (4 screws).

The rear light body mounting studs and nuts retain both the rear light body and the side marker bracket to the light bracket on the vehicle (Fig. 9).

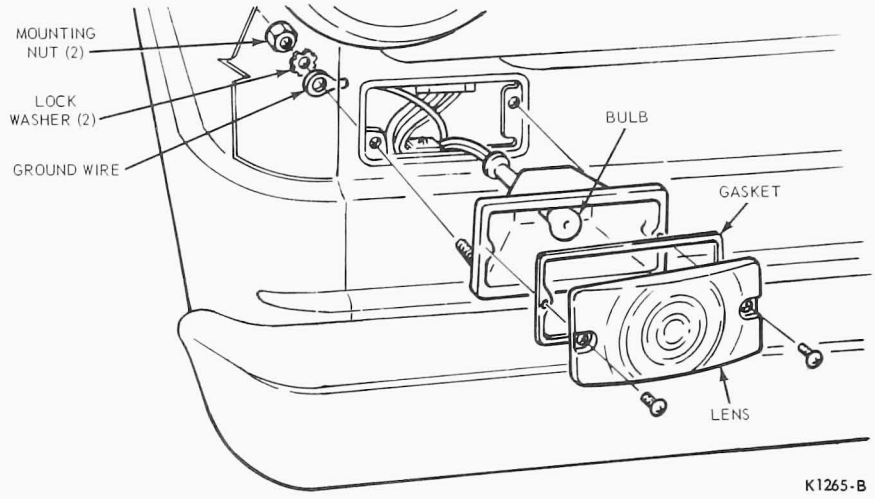

FIG. 4 Parking Light—Econoline, Typical of Bronco

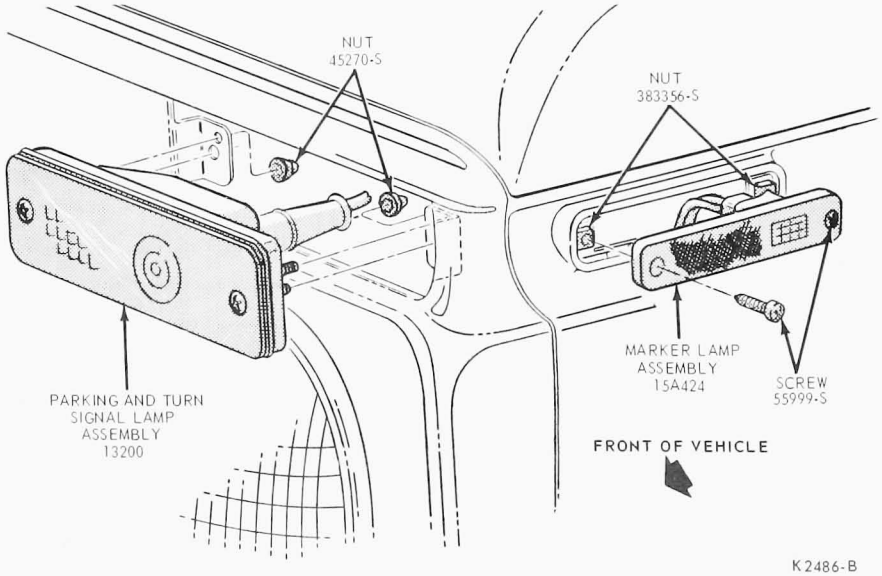

FIG. 5 Parking Light and Side Maker Light—F-100 through F-350

Therefore, the side marker and bracket assembly are dismounted from the light bracket when the rear light body is removed.

After removing the light body from the light bracket, disconnect the two connectors (red-black stripe wire and wire with green insulator) inside the frame side rail (Fig. 9). Unhook the wires from the retaining clip and pull the wires out through the grommets. Insert the studs of the replacement light body into the holes of the light mounting bracket, mount the side marker and bracket assembly and the ground wire to the studs and tighten the stud nuts. When routing the wires through the grommets, be sure to set the split line of the grommets in vertical position.

ALL TRUCKS EXCEPT E-AND U-100 AND PICK-UP

To replace a bulb, remove the lens and gasket (four retaining screws), turn the bulb counterclockwise and remove it from the socket.

To remove the light body, trace the lead wires along the frame side rail to the connector plugs and disconnect the wires at the connectors. Remove the bracket-to-side rail mounting nut that also holds the wire retaining clip to the bracket mounting bolt (Fig. 10). Remove the clip from the bolt and slide it off the wires. Pull the wires through the grommet in the side rail. Remove the light body-to-bracket mounting nuts and remove the light and wire assembly from the vehicle.

When installing the light body, route the lead wires through the hole in the bracket and the grommet in the side rail as shown in Fig. 10.

MARKER LIGHTS

F-100 AND F-250 STYLE SIDE PICK-UP, BRONCO AND ECONOLINE

Replacement of the bulb, the light assembly, or the socket and wiring assembly requires removal of the light assembly from the side of the vehicle (2 screws) as shown in Fig. 8. Disengage the bulb socket from the rear of the light assembly by turning clockwise. With the socket disengaged the light bulb can be replaced. If the socket and wiring assembly is to be replaced, disconnect the wiring at the connector and ground screw.

F-100 THROUGH F-350 FLARE SIDE PICK-UP

If only the side marker is being serviced, it can be removed from the bracket (2 retaining screws) as shown in Fig. 9. Disengage the bulb socket from

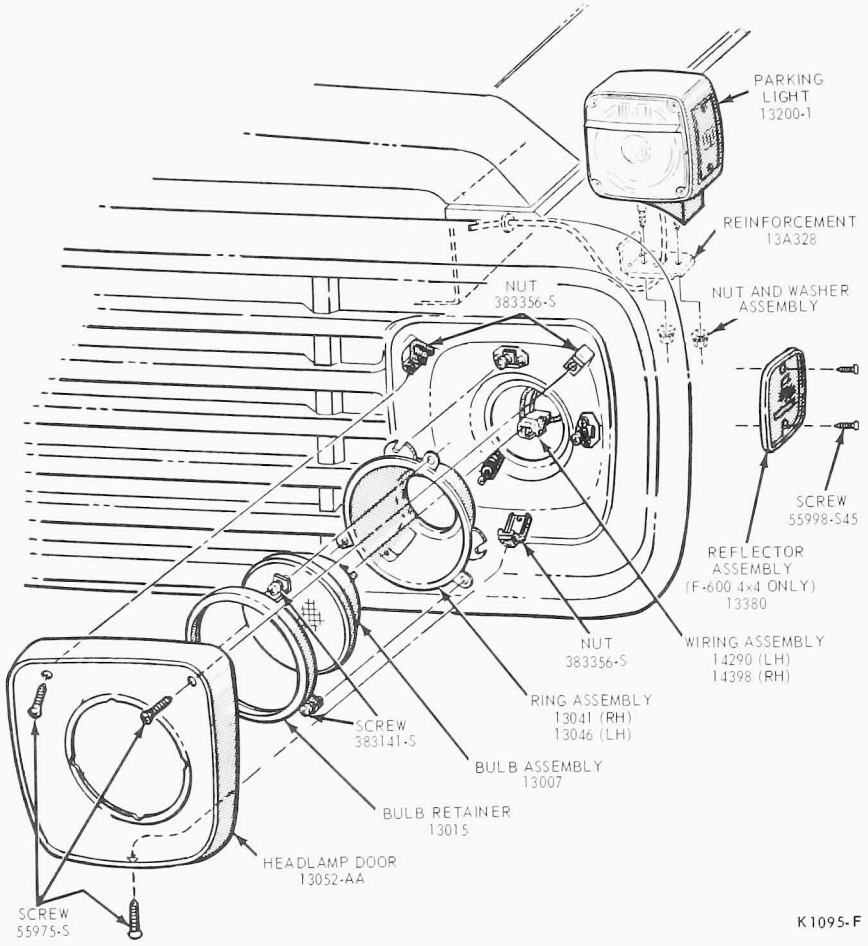

FIG. 6 Headlight, Parking and Turn Signal Lights—Typical 500 through 9000 Series

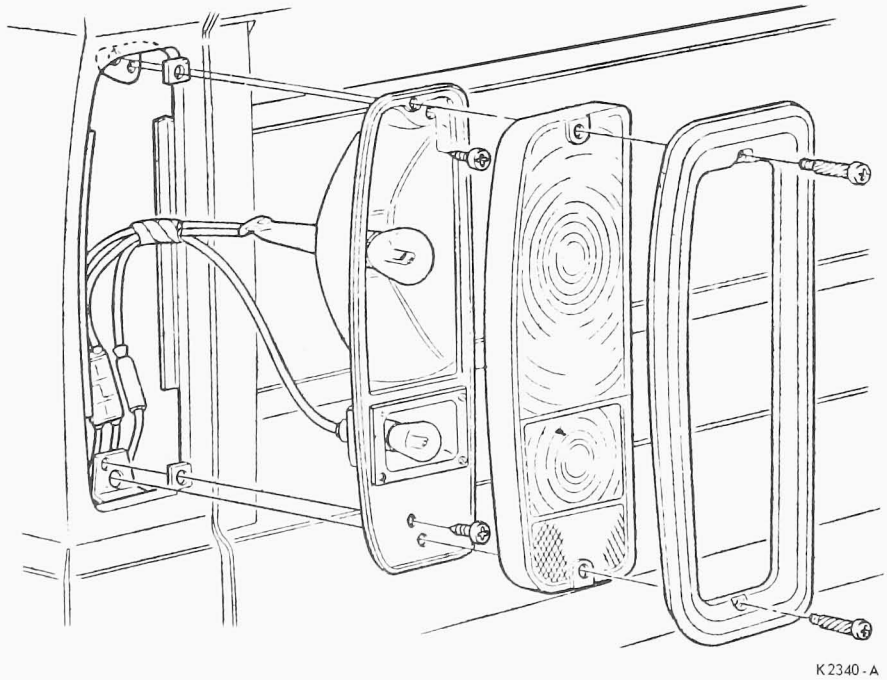

FIG. 7 Rear Light—Bronco and Econoline

the rear of the light assembly by turning counterclockwise. With the socket removed from the light assembly, the bulb can be replaced. If the socket and wiring assembly is to be replaced disconnect the brown wire at the connector inside the frame side rail (Fig. 9). Unhook the wire from the retaining clip and pull it out through the grommets. Disconnect the ground wire from the rear light stud (1 nut).

When routing the replacement wire through the grommets, set the split line of the grommets in vertical position.

CAB AND PLATFORM

Depending upon the particular vehicle, marker lights vary in number and location, but are all of the same basic design.

To replace the bulb, remove the lens (two retaining screws), press in on the bulb and turn it counterclockwise.

To remove the light body, remove the retaining nuts from the two mounting studs, disconnect the lead wire from the connector and withdraw the light body and wire assembly from the vehicle.

When installing the light body, be sure that the mounting pad is properly positioned between the light body and the vehicle sheet metal.

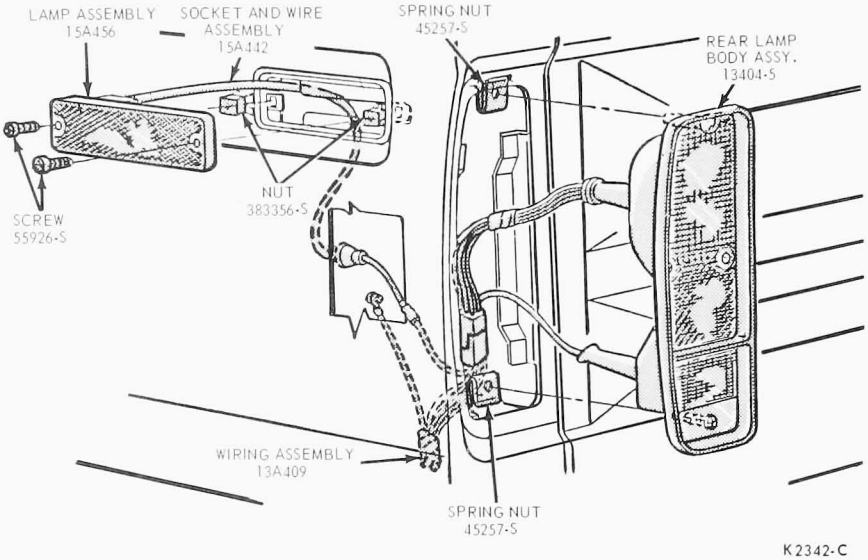

FIG. 8 Rear Light & Side Marker Styleside Pick-up

STOP LIGHT SWITCH

ECONOLINE

The Econoline stop light switch (Fig. 1) is mounted at the bottom of the brake pedal support bracket, just to the left of the brake pedal arm. Remove the switch by disconnecting the plug connector and unscrewing the switch from the retainer in the bracket. Install the switch by screwing it all the way into the retainer and connecting the plug connector.

F-100 THROUGH F-350

The F-100 through F-350 truck stop light switches are screwed into a threaded retainer on the brake pedal arm. To remove the switch, spread the plastic connector tabs and pull the electrical connector from the end of the switch body. Then unscrew the switch assembly from the retainer. To install, screw the switch assembly into the retainer fingertight, and install the electrical connector.

F-AND B-500 THROUGH 7000 SERIES AND BRONCO

To remove the stop light switch of an F-500 through F-750 truck, school bus, or Bronco with hydraulic brakes,

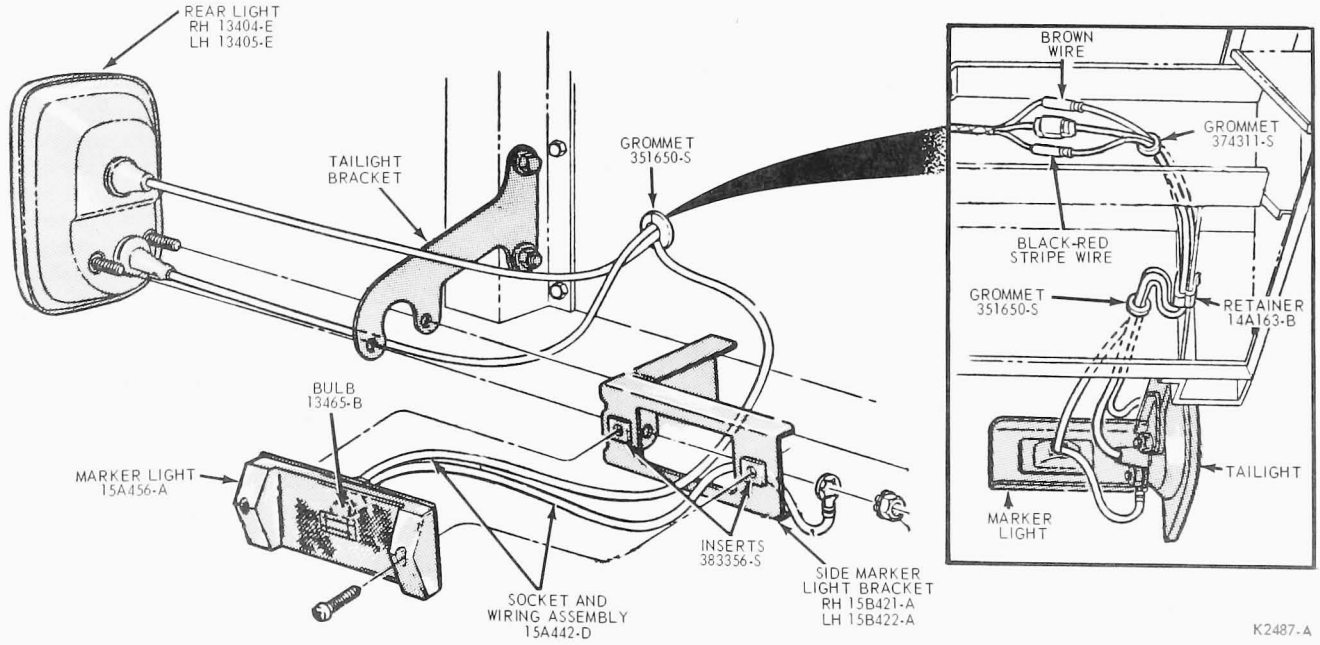

FIG. 9 Rear Lights—F-100 through F-350, Flare Side Pick-Up

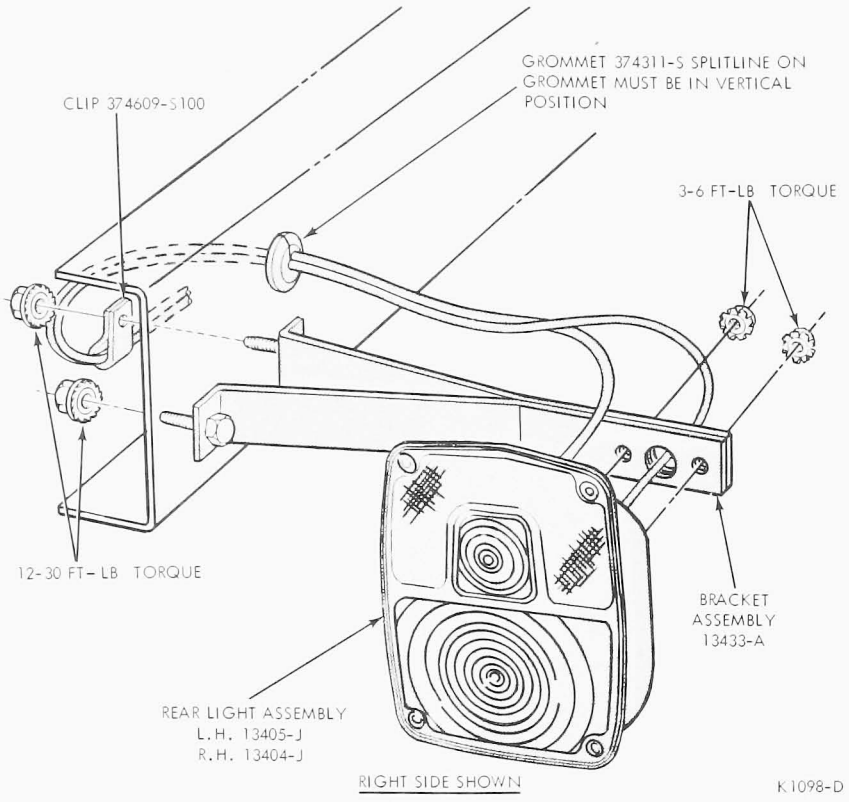

FIG. 10 Typical Rear Light Installation

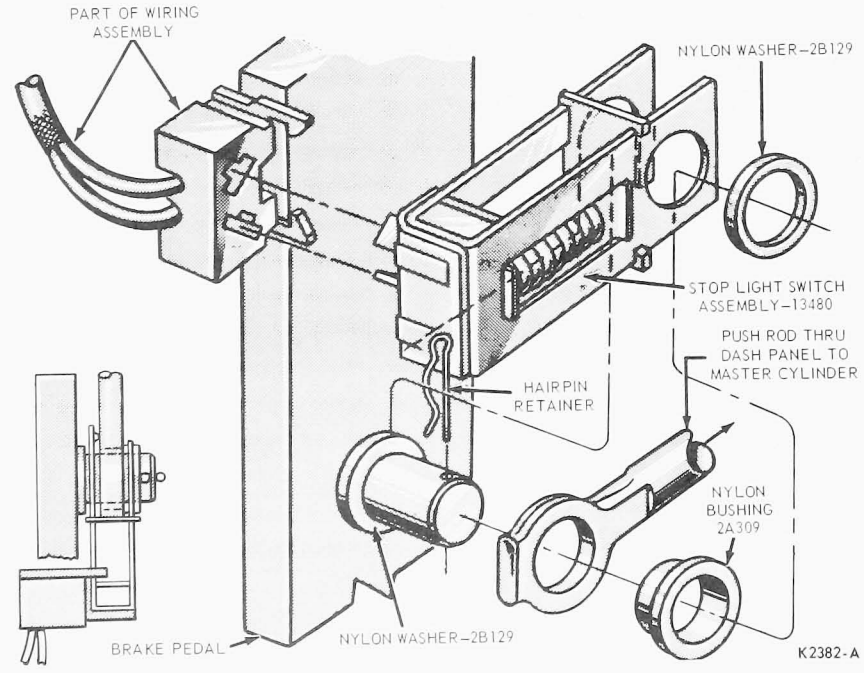

FIG. 11 Stop Light Switch—F-and B-500 through 750 Series and Bronco

disconnect the switch wiring connector under the instrument panel. Remove the push rod eccentric bolt and nut from the brake pedal arm, and remove the switch (Fig. 11). Remove the two nylon bushings from the push rod eye. To install the switch, coat the two bushings with lubriplate and position them in the push rod eye. Position the switch over the end of the push rod, and install the eccentric bolt and nut. Adjust the brake pedal free travel (Group 12).

PRESSURE SENSING STOP LIGHT SWITCH

To remove any pressure sensing stop light switch, disconnect the wire connectors at the switch and unscrew the switch body from the pressure port. If replacing a hydraulic pressure sensing switch, have the replacement switch ready for immediate installation to minimize fluid loss. After installing the wire connectors, coat the entire switch and connectors with ESB-M4G32-A or ESB-M4G31-A sealer. Fill and bleed the brake system (Group 12). To install an air pressure sensing switch, screw the switch body into the threaded pressure port and connect the wire connectors.

LICENSE PLATE LIGHT

ECONOLINE

To replace the bulb of the Econoline license plate light assembly (Fig. 12) pull the light socket out of the assembly from inside the left rear door. Remove the bulb, install a new bulb and press the socket into the light assembly.

To replace the lens of the light assembly, remove the two screws accessible from behind the rear door that retain the assembly to the door. Pull the light socket out of the light assembly and remove the assembly from the door. To remove the lens, straighten the tabs that retain the lens to the light body. Position a new lens to the light body and bend the tabs down to retain the lens. Position the light assembly to the door and install the two retaining screws. Install the light socket.

BRONCO

1. Raise the license plate bracket and remove the screw retaining the lamp assembly to the tailgate (Fig. 13). Pull the lamp assembly down and out of the tailgate.
2. Remove the lens and bulb. If

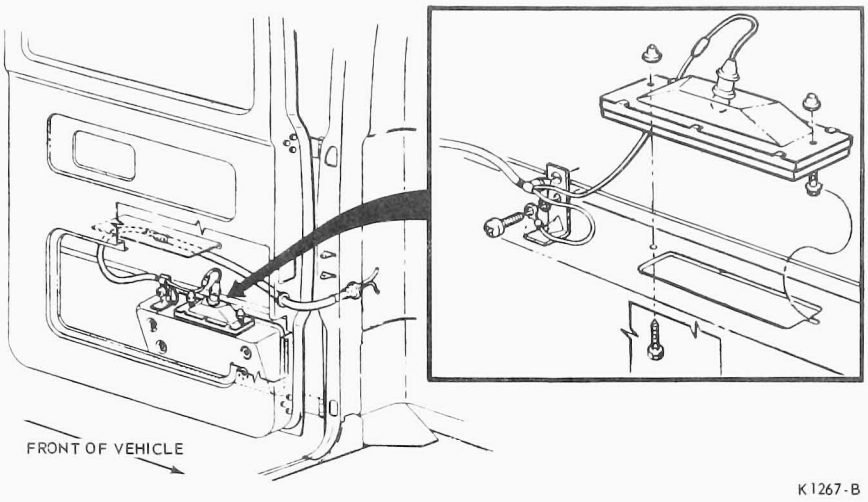

FIG. 12 License Plate Light—Econoline

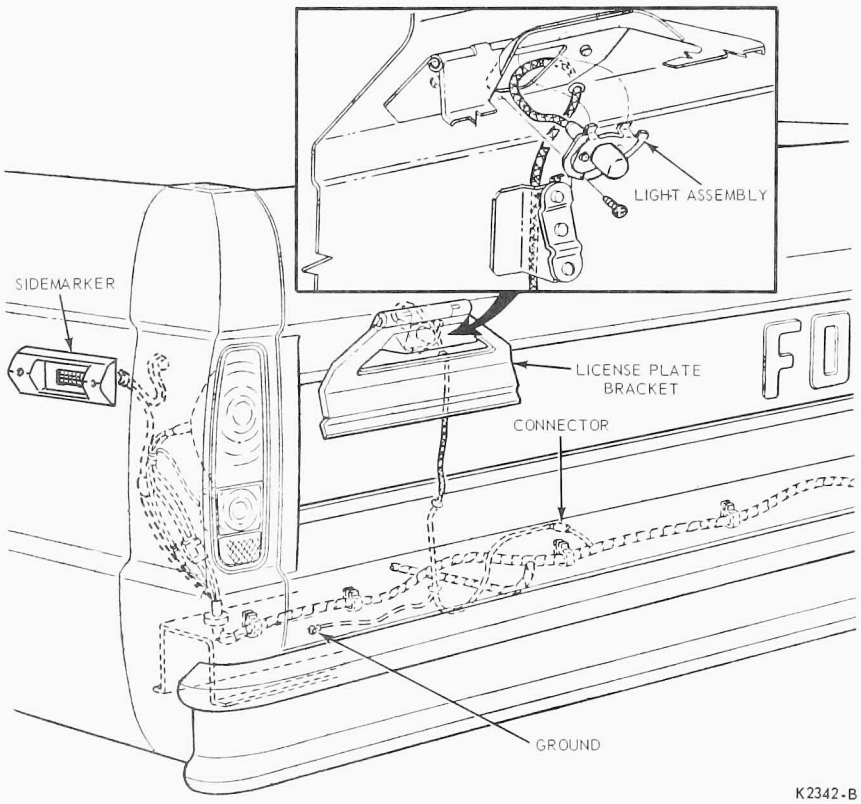

FIG. 13 Rear Lights—Bronco, Typical Econoline

replacing the light assembly, lower the tailgate for access and disconnect the light wires at the connector and the ground. Tape a pull-through wire or cord to the wires, remove the wire grommets from the holes in the tailgate, and remove the wire and light assembly.

3. If replacing the lamp assembly, transfer the weather seal to the new assembly and tape the new wires to the pull-through wire or cord. Pull the new wires and lamp assembly into position. Remove the pull-through wire or cord and connect both wires. Fit the grommets into the holes in the tailgate.
4. Install the lens and bulb. Install the screw retaining the lamp assembly to the tailgate and lower license plate bracket.

BACK-UP LIGHT SWITCH

ECONOLINE

The Econoline back-up light switch (Fig. 14) is accessible from the driver's seat. It is mounted under the steering column support plate at the lower edge of the instrument panel, adjacent to the shift tube. To remove the switch, disconnect the two wire connectors from the switch terminals, and remove the two screws fastening the switch and bracket assembly to the instrument panel. To install the switch, position the switch and bracket assembly under the steering column support plate and install the two retaining screws. Then connect the two wire connectors to the switch terminals, double wire connector at the top of the switch and single wire connector at the bottom.

If adjustment is needed, loosen the clamp screw of the switch actuator assembly on the shift tube. Shift the selector lever into Reverse and move the actuator assembly so that it depresses the switch plunger. Holding the actuator assembly in this position, tighten the clamp screw. Check the operation of the switch.

BRONCO AND F-100-350 WITH FORD 3-SPEED TRANSMISSION

The back-up light switch is mounted in the engine compartment, in a bracket secured to the forward end of the

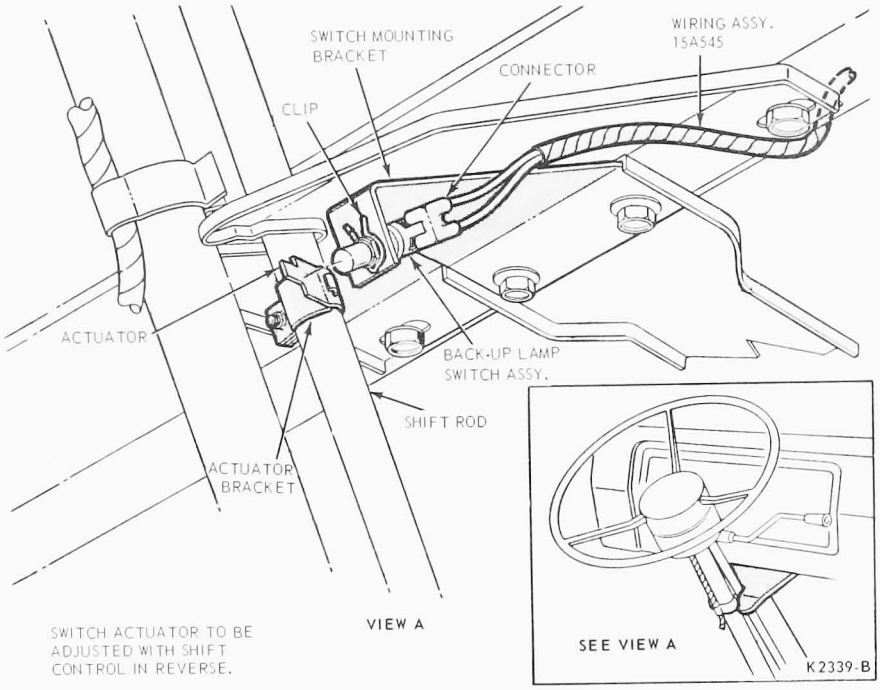

FIG. 14 Back-Up Light Switch—Econoline

steering column tube by a clamp (Fig. 15). To remove the switch, place the transmission selector lever in some position other than reverse, and disconnect the two connectors from the switch terminals. Remove the switch retaining clip. To install the switch, set it in position and install the retaining clip. Connect the wire connectors to the switch terminals.

If adjustment is needed, loosen the screw on the bracket clamp and move the bracket and switch so that the steering column shift lever will actuate the switch in reverse, but not in neutral. Tighten the clamp screw.

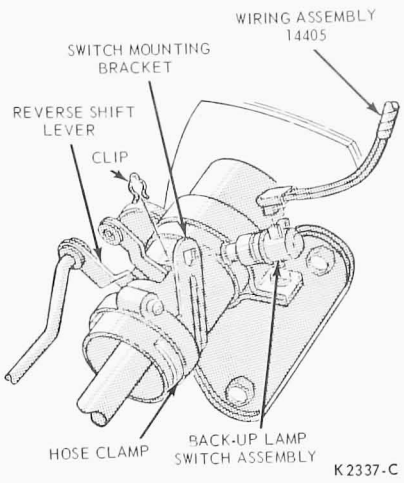

FIG. 15 Back-Up Light Switch—Bronco, Typical of F-100, F-350

ALL TRUCKS OTHER THAN BRONCO, ECONOLINE AND F-100-350 WITH FORD 3-SPEED TRANSMISSION

The back up light switch on all of these vehicles is a part of the transmission assembly. Refer to Group 16.

PART 32-41 Turn Signals and Hazard Flashers

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION		REMOVAL AND INSTALLATION – Cont.	
Turn Signal and Hazard Flasher System	41-01	Flasher Units	41-03
REMOVAL AND INSTALLATION		Turn Signal Switch	41-01
Hazard Flasher Switch	41-02		

DESCRIPTION AND OPERATION

TURN SIGNAL AND HAZARD FLASHER SYSTEM

ALL EXCEPT BRONCO AND ECONOLINE

On F-100 through F-350 trucks, the turn signal/hazard flasher switch is located in the upper steering column hub. The turn signal switch is operated by a lever on the left side of the hub. The turn signal flasher unit is clipped to the top left of the instrument cluster housing back. The hazard flasher switch is mounted on the right side of the steering column hub.

A single transistorized flasher unit which serves both the turn signal and hazard flasher circuits is used on all trucks above the F-100 through F-350 models. The flasher unit is mounted on the brake pedal support.

Two types of turn indicators are used. One type has the front indicator lights mounted on the front fenders. The other unit uses the dual filament parking lights for the indicator lights.

To operate the turn signals, the ignition switch must be in either the ACC or ON positions. The hazard flasher system is operated independently of the ignition switch by activating the hazard flasher switch. Two flasher units are used, one for the turn signal circuit and the other for the hazard flasher signal circuit.

BRONCO

The Bronco turn signal switch is located in the steering column hub and is operated by the turn signal switch lever at the left side of the steering column. The turn signal flasher unit is mounted in a clip on the left side of the instrument panel brace, between the top of the instrument cluster and the steering column.

The Bronco hazard flasher switch is a push button in the instrument panel, just below the headlight switch. The hazard flasher signal flasher unit is clipped to the rear of the hazard switch.

ECONOLINE

The Econoline turn signal and hazard flasher signal switches are integral parts of the same switch assembly in the steering wheel hub. The turn signal switch lever is at the left side of the steering column hub. The hazard flasher switch knob is a push button mounted in the right side of the hub. The turn signal flasher unit is mounted in a clip attached to the top left side of the back of the instrument cluster. The hazard signal flasher unit is clipped to the right side of the brake pedal support.

REMOVAL AND INSTALLATION

TURN SIGNAL SWITCH

BRONCO

Removal

1. Disconnect the horn and turn signal wires at the connectors located behind the instrument panel. Remove the steering column wires and terminals from the connectors with Tool No. C4AZ-17018-B, as shown in Fig. 1. **Record the color code and location of each wire before removing it from the connector plug.** Tape a pull-through wire or cord to one of the wire ends.
2. Depress the horn button or horn ring and rotate it counterclockwise to remove it. Remove the horn spring.
3. Mark the steering wheel position on the steering column. Remove the steering wheel attaching nut. Remove the steering wheel with Tool No. 3600-AA. Remove the spring from around the end of the steering shaft.
4. Turn the turn signal switch lever counterclockwise to remove it. Remove the screws and retainer that hold the turn signal switch and wire assembly to the steering column, and pull the assembly from the column. Disconnect the pull-through wire or cord from the end of the switch wire.

Installation

1. Tape the loose ends of the new turn signal switch wires to the pull-through wire or cord. Carefully pull the wires through the steering

column while guiding the turn signal switch into position. Install the switch retainer and screws.

2. Install the turn signal lever. Apply lubricant (COAZ-19584-A) to the horn brush contact plate. Position the steering wheel over the shaft spline and install so that the center spoke is as close to vertical position as the splines permit. The center spoke is located vertically below the centerline of the steering shaft. Use a new retaining nut (No. 382702-S100) and start by hand. The nut faces are symmetrical and the nut may be started with either face downward on the shaft.

Hand-torque the nut to 45-55 ft-lbs and stake the nut to the steering shaft at one point only.

3. Install the spring and the horn button or ring on the steering wheel hub.
4. Remove the tape holding the pull-through wire or cord to the switch wires. Press the switch wires into the connector blocks in their correct locations as recorded during removal. Connect the connectors. Check the operation of the switch.

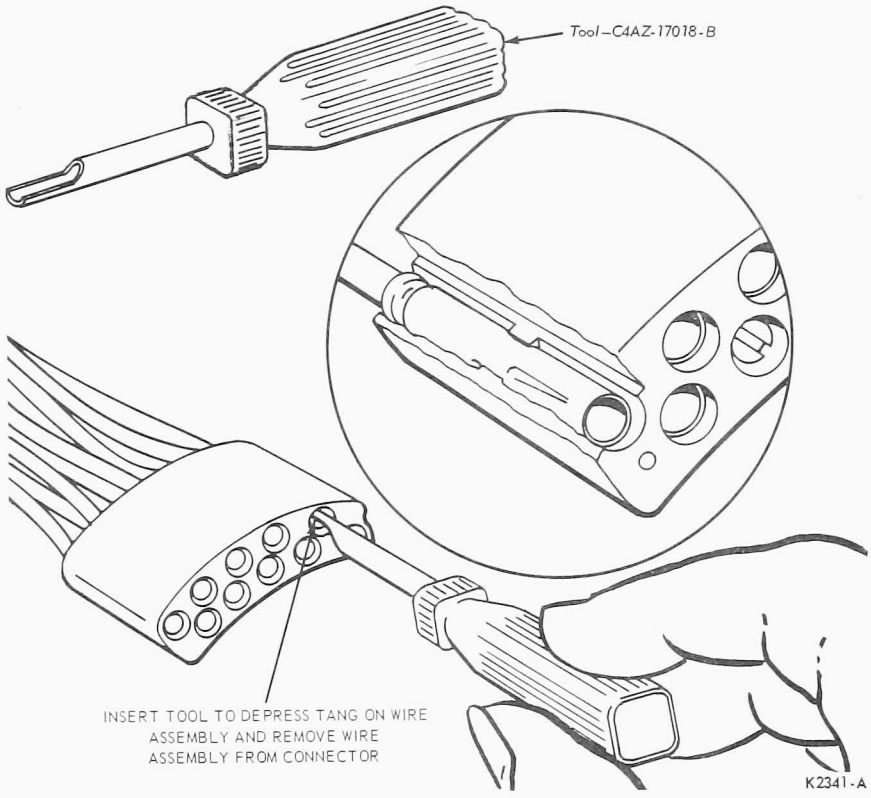

FIG. 1 Wire Terminal Removal

HAZARD FLASHER SWITCH

BRONCO

1. Loosen the set screw in the switch knob and remove the knob. Remove the nut and bezel, and remove the switch and bracket assembly from behind the instrument panel.
2. Pull the hazard flasher unit from the clip on the switch bracket. Disconnect the wire connector to the switch.
3. Connect the wire connector to the hazard flasher switch. Insert the flasher unit in the clip on the switch bracket.
4. Place the switch and bracket assembly in position, aligning the small hole in the face of the bracket with the corresponding hole in the instrument panel. Set the bezel in position and install the retaining nut. Slip the switch knob on the switch shaft and tighten the screw.

TURN SIGNAL/HAZARD FLASHER SWITCH

ECONOLINE

Removal

1. Disconnect the horn and turn indicator switch wires under the instrument panel from the connectors with Tool number C4AZ-

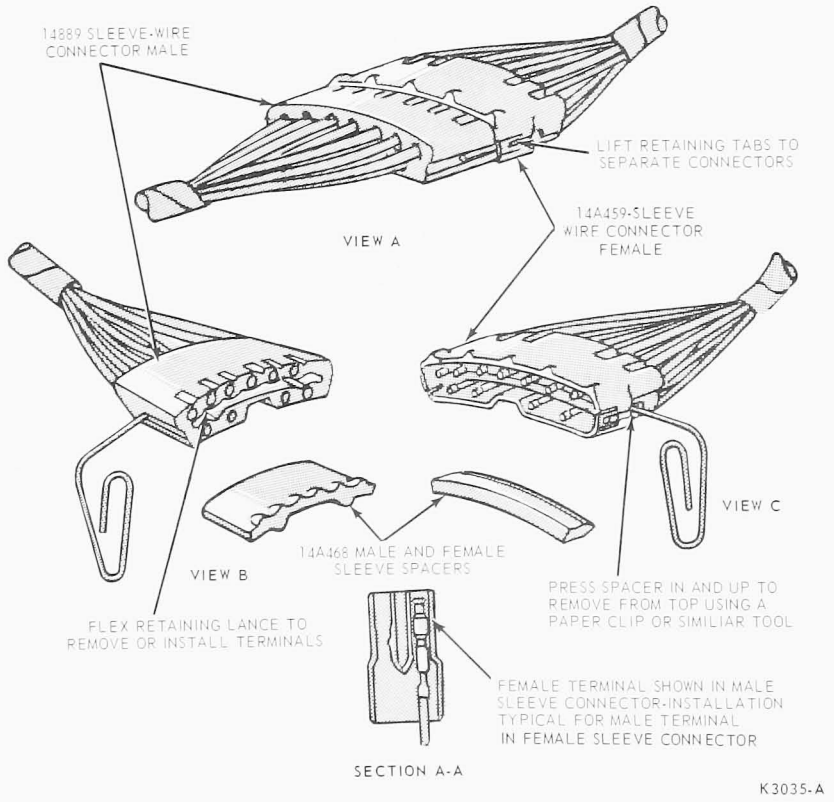

FIG. 2 Ignition Switch Wire Connector—F-100-250-350, F-100-250 4 x 4

17018-B (Fig. 1). Disconnect above wires at the clips on the steering column support.
2. Press down evenly on the horn button and turn counterclockwise until it lifts out from the steering wheel. Remove the horn button and spring.
3. Mark the steering wheel position on the steering column. Remove the steering wheel retaining nut and the steering wheel.
4. Turn the turn signal switch level counterclockwise to remove. Remove the cover that retains the turn indicator wires to the steering column.
5. Remove the two retaining screws under the steering column cup, and lift the horn contact plate and turn indicator assembly from the steering column cup.

Installation

1. Position the new horn contact plate and turn indicator switch assembly into the steering column cup, and install the retaining screws.
2. Apply lubricant (COAZ-19584-A) to the horn brush contact plate. Position the steering wheel over the shaft spline and install so that the center spoke is as close to vertical position as the splines permit. The center spoke is located vertically below the centerline of the steering shaft. Use a new retaining nut (No. 382702-S100) and start by hand. The nut faces are symmetrical and the nut may be started with either face downward on the shaft.

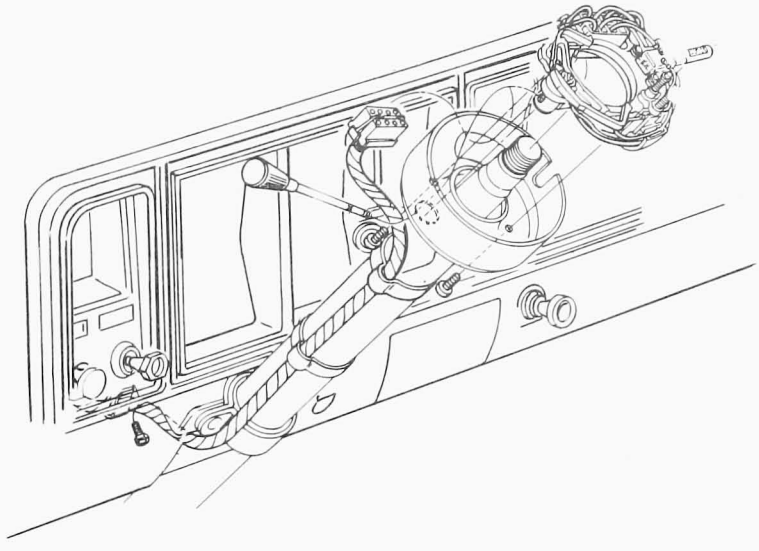
Hand-torque the nut to 45-55 ft-lbs and stake the nut to steering shaft at one point only. Position the spring over the steering shaft, and install the horn button.

3. Secure the turn indicator handle to the steering column flange, tape the horn wire to the turn indicator wires and secure the cover over the wires and to the steering column.
4. Route the wires through the retaining clips and connect them under the instrument panel.
5. Check the operation of the two signals and the horn.

F-100-350, F-100-250 4 X 4

Removal

1. Disconnect the battery ground cable.
2. Remove the horn switch.
3. Remove the steering wheel retaining nut and using Tool 3600AA, remove the steering wheel from the shaft.
4. Remove the turn signal switch lever by unscrewing it from the steering column.
5. Disconnect the steering column wiring connector plug by lifting up on the tabs and separating (Fig. 2) and remove the screws that secure the switch assembly to the column.
6. Remove the wires and terminals from the steering column wiring connector plug (Fig. 2). Record the color code and location of each wire before removing it from the connector plug.
7. Remove the protective wire cover from the wiring harness and remove the switch and wires through the top of the column (Fig. 3).



K1487-C

FIG. 3 Hub Mounted Turn Signal/Hazard Flasher Switch Removal

Installation

1. Feed turn signal/hazard flasher switch wires through area provided in column.
2. Install screws retaining switch assembly to column.
3. Install protective wire cover over wires and slide 3.25-3.75 inches into column (column lower end).
4. Install wires into steering column wire connector terminal and connect terminals.
5. Install turn signal lever and test turn signal operation, hazard signal operation and PRND12 diallight (if so equipped).
6. Install steering wheel.
7. Install horn switch.
8. Connect battery ground cable.

TURN SIGNAL/HAZARD FLASHER SWITCH (SIDE MOUNTED TO STEERING COLUMN)

1. Disconnect the multiple connector immediately below the turn signal/hazard flasher switch assembly atthe side of the steering column.
2. Disconnect the horn switch multiple connector at the top rear of the steering column hub.
3. Remove one screw and clip from the turn signal housing to release the strap retaining the assembly to the steering column, and remove the turn signal/hazard flasher switch assembly.
4. Position the switch assembly to the steering column and install the screw and clip retaining the strap to the assembly.
5. Connect the multiple connectors to the wiring at the steering column and to the horn switch, and test the operation of the switch.

FLASHER UNITS

To remove a conventional flasher unit from F-100-350 trucks, pull the flasher unit from its retaining clip and disconnect the wiring connector. Install by connecting the connector and pressing the flasher unit into the retaining clip.

To remove a transistorized flasher unit, disconnect the battery ground cable. Then remove the two screws retaining the flasher unit, disconnect the push-on terminals and remove the flasher unit. To install, position the flasher unit to the brake pedal support and install the two retaining screws. Connect the push-on connections. Connect the battery ground cable.

The Econoline instrument cluster must be removed for access to the turn signal flasher. To replace a flasher unit, disconnect the wire connector from the terminals and pull the flasher from the

mounting clip or bracket. **When replacing a turn signal flasher unit, be sure to install a new flasher unit having the same color code and number as the one removed.**

PART 32-61 Interior Lights

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION		REMOVAL AND INSTALLATION – Cont.	
Interior Lights	61-01	Courtesy Light	61-02
REMOVAL AND INSTALLATION		Courtesy Light Switch	61-02
Cargo Light	61-02		

DESCRIPTION AND OPERATION

INTERIOR LIGHTS

Bronco's courtesy light is centrally located at the bottom edge of the instrument panel. The bulb is energized when the headlight switch knob is turned fully counterclockwise.

ECONOLINE

The overhead courtesy light and cargo light for Econoline is controlled by the headlight switch and switches located in the door jams.

The bulbs are energized when the headlight switch knob is turned fully counterclockwise and also when the door is opened.

F-100 THROUGH F-350, F-100-250 4 X 4 AND BRONCO

The courtesy light is located above the rear window and is energized when the headlight switch knob is turned fully counterclockwise.

All models of the F-100 through F-600 series are equipped with door jam switches which also control the courtesy light.

The cargo light on F-100 through F-350 series is located outside above the rear window and is controlled by a switch mounted behind the drivers door on the upper inner finish panel (Fig. 1).

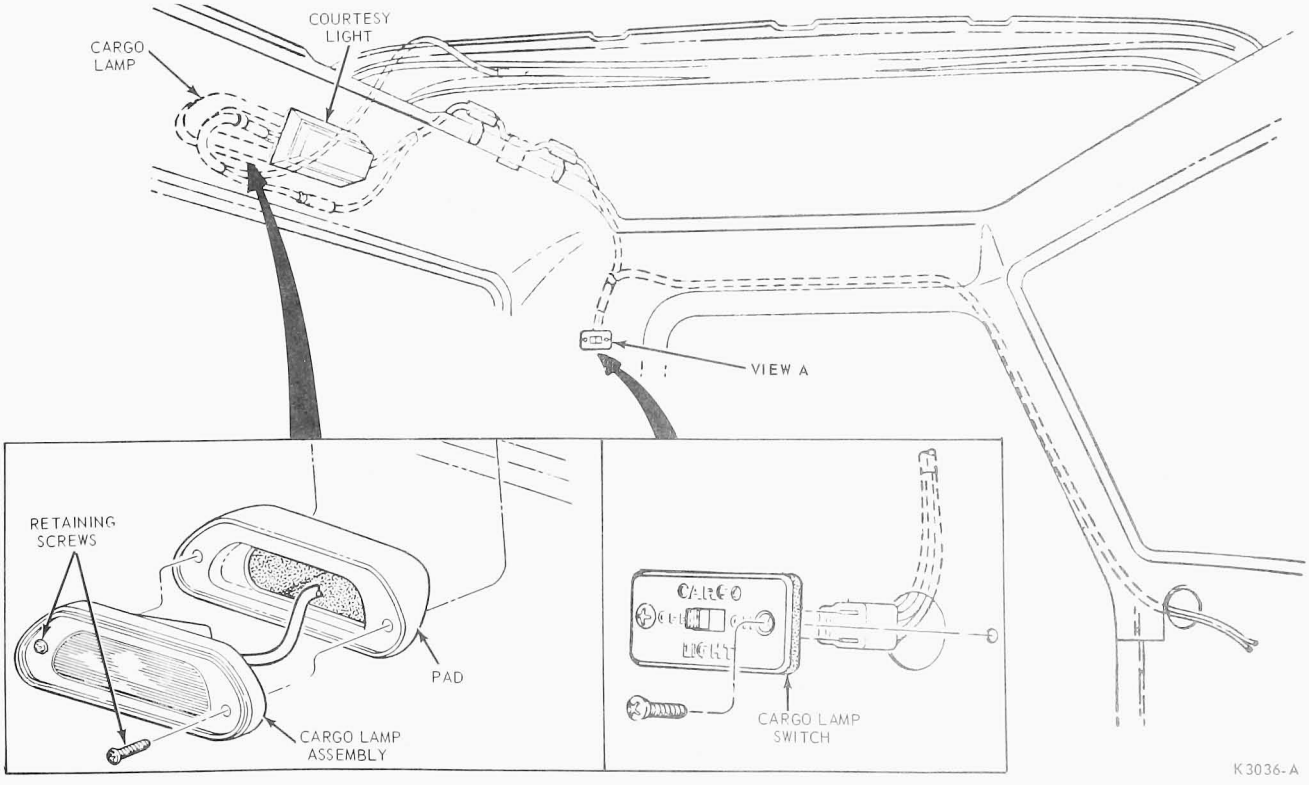


FIG. 1 Cargo Lamp and Switch—F-100-350

REMOVAL AND INSTALLATION

COURTESY LIGHT

BRONCO

Bulb replacement requires only removal of the bulb and installation of the new bulb. No lens or door is used on the Bronco courtesy light. To remove the light assembly, remove the retaining screw and disconnect the lead.

F-100-350

Remove the two lens and door retaining screws and remove the bulb (Fig. 2). To install, position the lens and door and install the two lens and door retaining screws.

CARGO LIGHT

Remove the two lens and door retaining screws and remove the bulb. To install, position the lens and door and install the two retaining screws.

CARGO LIGHT SWITCH

Remove the two screws retaining the switch assembly. Disconnect the wire connector and remove the switch.

COURTESY LIGHT SWITCH—DOOR JAM

Use a thin bladed screwdriver and carefully pry the switch from the door jam. Disconnect the wire connector and remove the switch.

N/A indicates that the item is not applicable to the vehicle(s) listed.

DESCRIPTION AND OPERATION

SPEEDOMETER SYSTEM

The speedometer is connected to the output shaft of the transmission by means of a flexible shaft (core), and a drive gear located inside the transmission. The core drives the speedometer which registers speed in miles per hour and also drives an odometer which records distance traveled in miles and tenths of a mile.

The core or flexible shaft is housed in a flexible casing. The core and casing assembly is referred to as the speedometer cable.

TESTING

SPEEDOMETER

To test the odometer accuracy, drive the truck over a measured mile. Speedometer accuracy can be checked by comparing the speedometer in question against one known to be accurate, while two trucks are moving at the same speed, or by timing the truck on a measured mile. Refer to Speedometer Calibration Tolerance Specifications, in this Part. The Ford Truck Master Parts Catalog shows the proper speedometer gears to use for various rear axle and tire size combinations.

REMOVAL AND INSTALLATION

SPEEDOMETER HEAD

BRONCO

Removal

1. Disconnect the battery ground cable and remove the instrument cluster, following instructions under Instrument Cluster Removal, Group 33, Part 50.
2. Remove the instrument cluster plate, lens and mask from the cluster.
3. Remove the speedometer retaining screws and pull the speedometer from the cluster assembly.

Installation

1. Position the speedometer assembly in the cluster housing and install the retaining screws.
2. Install the instrument cluster plate, lens and mask.
3. Install the instrument cluster and connect the battery ground cable, following instructions under Instrument Cluster Installation, Group 33, Part 50. Check the operation of the speedometer.

ECONOLINE

To remove the speedometer, remove the retaining screws at the back side of the cluster and remove the speedometer retaining screws from the front side. Pull the speedometer out from the front.

Position the speedometer to the front side of the cluster housing and install the retaining screws from the front. Install two retaining screws from the back side of the housing.

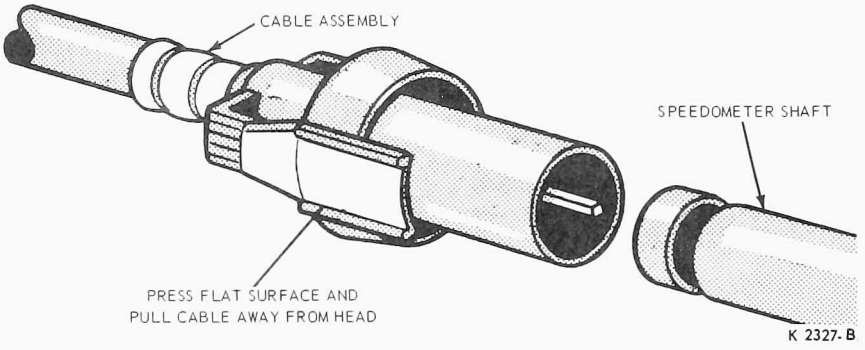

FIG. 1 Speedometer Cable Quick-Connect

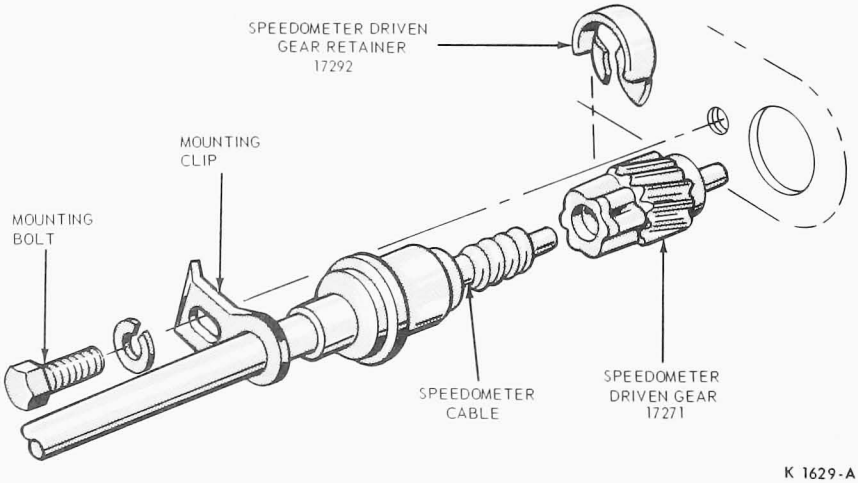

FIG. 2 Speedometer Driven Gear Mounting at Transmission

F-100 THROUGH F-350

Remove the instrument cluster as outlined in this Group. Remove the lens and mask from the cluster. Remove 2 speedometer attaching screws and remove speedometer and seal. To install, place the seal on back of speedometer, and install the attaching screws. Install the mask and lens, then the instrument cluster.

ALL TRUCK LINES EXCEPT BRONCO, ECONOLINE AND F-100 THROUGH F-350

1. Disconnect the battery ground cable.
2. Remove the instrument cluster assembly from the instrument panel.
3. Remove the retaining screws and remove the speedometer mounting plate and gauges from the cluster bezel.
4. Remove the screws retaining the speedometer to the mounting plate and remove the speedometer.
5. Position the new speedometer on the mounting plate and install the retaining screws.
6. Position the speedometer mounting plate and gauges on the cluster bezel and install the retaining screws.
7. Install the instrument cluster assembly to the instrument panel.
8. Connect the battery ground cable.

SPEEDOMETER CORE

Removal

1. Disconnect the speedometer cable (core and casing assembly) from the speedometer head (Fig. 1).
2. Pull the speedometer core out of the upper end of the casing.
3. If the core is broken, raise the vehicle on a hoist and remove the bolt retaining the speedometer cable mounting clip to the transmission.
4. Remove the shaft and driven gear from the transmission (Fig. 2). Remove the driven gear retainer, and remove the driven gear and shaft from the cable.
5. Remove the lower part of the core (if it is broken) from the lower end of the casing.

Installation

1. Position the driven gear to the casing and install the gear retainer. Install the driven gear and casing in the transmission, and install tthe retaining bolt. Lower the vehicle.
2. Determine the exact length of the old core and cut the new core so that it is 13/16 of an inch shorter than the old core. (Do not cut from the squared end of the core). Remove any burrs or frayed edges.
3. Install the tip on the core, making certain to seat the core in the bottom of the tip.
4. Place the core and tip in a crimping die, and place the die on a solid surface and strike it squarely with a hammer to crimp it.
5. Remove the crimping die.
6. Lubricate the core with cable lubricant D2AZ-19581-A (do not over lubricate). Install the core (square end first) into the upper end of the casing and push it all the way through to the transmission (Fig. 3). When the cable is nearly seated, twist it slightly to make sure that the squared end is engaged in the speedometer driven gear at the transmission.
7. Connect the cable assembly to the speedometer, being sure to eliminate any kinks in the housing and shaft. Check the operation of the speedometer.

SPEEDOMETER CORE AND CASING

BRONCO

Disconnect the speedometer cable from the speedometer head and push the cable and grommet through the opening in the floor pan or dash panel. Raise the vehicle on a hoist and disengage the cable from all retaining clips. Disconnect the cable from the transmission and connect the new cable to the transmission. Engage the new cable in the retaining clips at the marker tapes on the cable housing and route it through the opening in the floor pan or dash panel. Push the grommet in place. Lower the vehicle and connect the cable to the speedometer head.

ECONOLINE

Removal

1. Disconnect the speedometer cable and housing from the speedometer. Work the cable grommet out of the hole in the dash panel and carefully pull the cable and housing out through the front of the dash panel.
2. Raise the vehicle on a hoist and remove the bolt and lock washer retaining the speedometer cable housing clamp to the transmission (Fig. 4). Remove the cable and driven gear from the transmission. Note relationship of the cable to the body crossmember for reference during installation.
3. Disengage the cable assembly from the three clips along the flange of the underbody structural member. Work the cable grommet out of the hole in the crossmember and remove the cable assembly from the vehicle by guiding it rearward and out of the crossmember.

Installation

1. Transfer the speedometer cable driven gear and O-ring to the new cable.
2. Lubricate the cable core sparingly with B5A-19581-A lubricant and insert the cable core into the housing. Lubricate the O-ring with COAZ-19584-A lubricant. Lubricate the driven gear with graphite grease.
3. Feed the speedometer cable assembly forward through the grommet hole in the underbody crossmember, then route the cable assembly to the trasnmission (ahead of the transmission support crossmember with manual transmission; through the hole in the center of the crossmember with six-cylinder automatic transmission, or behind the crossmember with eight-cylinder automatic transmission).
4. Insert the driven gear into the transmission, rotating the cable core slightly to mesh the gears. Attach the cable housing clamp to the transmission with the bolt and lock washer to secure the cable assembly.
5. Press the cable assembly into the three flange clips at the tape bands on the cable housing. Work the cable grommet about two inches into the hole in the underbody crossmember. Guide the forward end of the cable assembly up into the underhood area where it can be reached when the vehicle is lowered.
6. Lower the vehicle and route the speedometer cable through the underhood area in the following manner (Fig. 4). The front and rear brake lines come out of the left side of the master cylinder and double back under the master cylinder. The speedometer cable assembly should pass to the left of the master cylinder. **Ahead** of both brake lines where they pass under the master cylinder and **between** both brake lines where they come out of the side of the master cylinder. From there, the cable assembly should be routed up and into the hole in the dash panel.
7. Position the cable assembly to the speedometer and install the cable housing hex nut finger tight. Then tighten the nut to the specified torque.
8. Work the cable grommet into the hole in the dash panel about one inch. Make sure that there are no

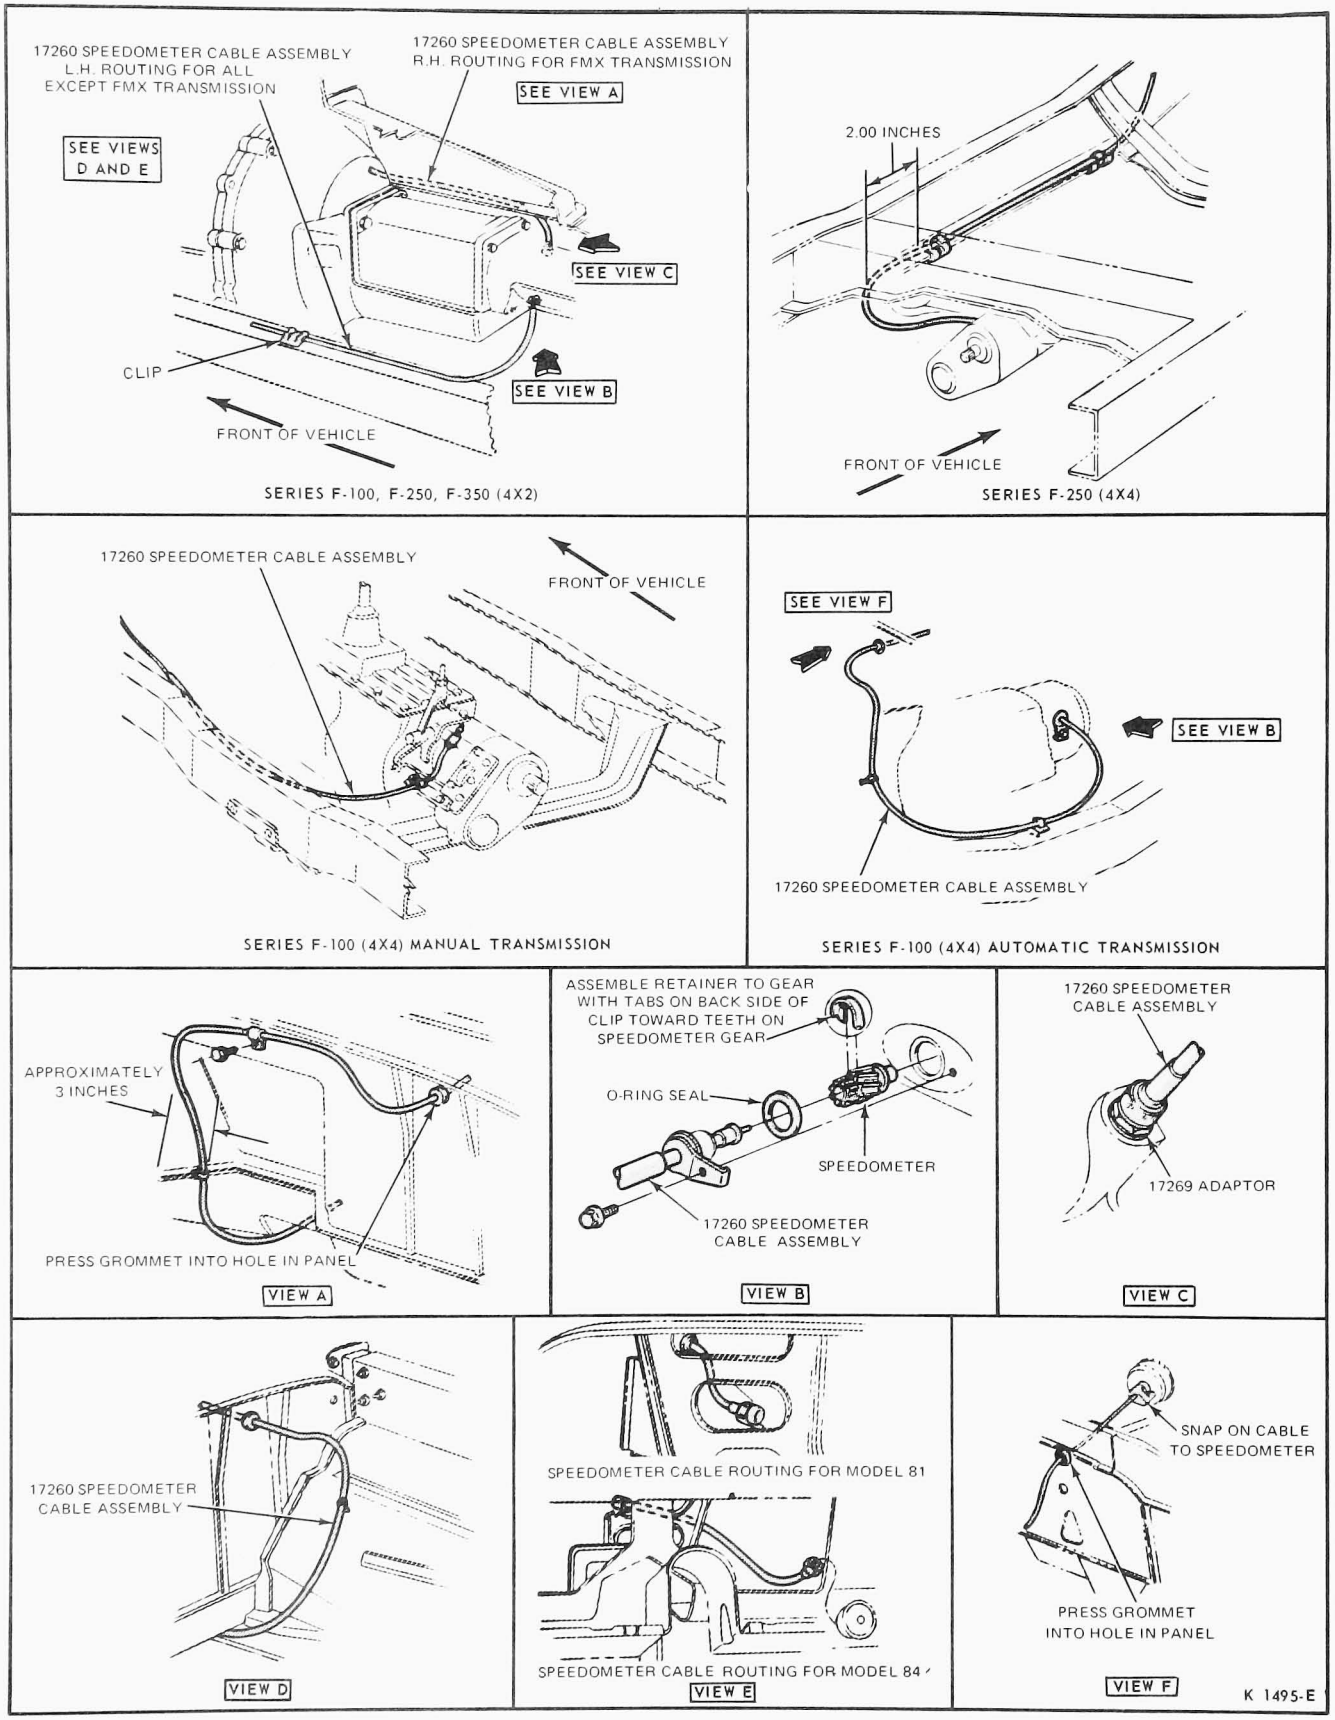

FIG. 3 Speedometer Cable Routing

sharp bends in the cable assembly. Then check the speedometer operation.

F-100 THROUGH F-350

Disconnect the speedometer cable casing from the speedometer head and push the cable and grommet through the opening in the floor pan or dash panel. Raise the vehicle on a hoist and disengage the cable from all retaining clips and/or clamps. On vehicles so equipped, work the cable grommet out of the crossmember. Note the location of the various mounting clips, clamps, bolts and nuts and their relationship to the cable for reference during installation. Disconnect the cable assembly from the transmission (Fig. 3). Remove the assembly from the vehicle.

Lubricate the cable core sparingly with B5A-19581-A lubricant and insert the core into the casing.

On vehicles where the cable is retained to the transmission by a mounting clip and bolt, transfer the driven gear and O-ring with COAZ-19584-A lubricant and the driven gear with graphite grease. Tighten the mounting clip bolt to the specified torque.

MAJOR REPAIR OPERATIONS

DRAGGING CABLE CORE AND HEAD

Before removing a speedometer head, disconnect the cable at the head and insert a short section of cable core in the head. Rotate the section of core to check for any dragging or noise. The shaft in the speedometer head should turn freely and evenly.

If a new speedometer head is being installed, examine the square drive hole for sufficient lubricant. If lubricant is needed, apply a 3/16-inch diameter ball of C5AZ-19581-A lubricant in the drive hole.

DAMAGED CABLE CORE AND CASING

1. To check for a kinked cable core remove and wipe dry. Lay the core out straight on a flat surface and roll it back and forth. Any kinks or damage will be seen. Then take an end in each hand, allowing core to hang in approximately a 9 to 12 inch loop. Rotate both ends to be sure core turns evenly.
2. Routing of the cable casing is particularly important where the cable leaves the speedometer head. The optimum routing would provide that the cable and housing take virtually no change of direction for at least a length of 8 inches from the speedometer head.
3. When installing a new cable (core and casing) it is necessary that extra care be taken to see that the new assembly is guided and routed properly to eliminate any kinks.
4. Proper lubrication of the cable core is accomplished by a light application of B5AZ-19581-A lubricant after the cable has been wiped clean. A light film is all that is required.

DAMAGED DRIVE AND DRIVEN GEARS

1. A scored, nicked or gouged driven gear is usually indicative of a damaged drive gear on those vehicles that have the drive gear integral with the transmission output shaft. The output shaft should be carefully inspected for imperfections and replaced if necessary.
2. A driven gear with two or three adjoining teeth badly scored is indicative of improper assembly procedure. The gear should be inserted in the transmission while simultaneously turning the drive shaft. This will insure initial gear engagement and prevent gear damage. **Force should never be used.**
3. Whenever a drive gear is replaced, a new driven gear should also be installed, regardless of its apparent condition.

CABLE CORE

On trucks without fittings or drive adaptors connected to the cable between the speedometer and driving end, disconnect the speedometer cable at the speedometer head.

Jack up the rear wheels, start the engine and check for speedometer core rotation at the disconnect point. If the core does not rotate, disconnect the cable from the transmission or right wheel (driving end) and check for damaged gears or drive tip. Replace as required. If the gears and drive tip are in good condition, the core is broken.

Pull the upper portion of the broken core from the driven end of the casing (at the speedometer head, fitting or drive adaptor). Measure the length of this removed part of the core in order to locate the trouble. The most likely trouble spot will be a point on the cable casing whose distance from the driven end is equal to the length of the removed core piece. Check for a crushed or broken cable or for a sharp bend at this point. Replace the cable or increase the cable radius as required.

SPECIFICATIONS

CK2492-A

PART 33-04 Tachometer

DESCRIPTION AND OPERATION

TACHOMETER SYSTEM

The tachometer used in Ford trucks is a cable driven instrument which records engine speed in Revolutions Per Minute (RPM).

Trucks equipped with the super-duty engines incorporate a mechanical governor from which the tachometer cable is driven. In trucks equipped with the heavy duty gasoline engines, the tachometer is driven from a tachometer drive gear located in the distributor assembly.

The tachometer cable is driven off of various engine components on trucks equipped with diesel engines.

REMOVAL AND INSTALLATION

TACHOMETER HEAD

From behind the instrument cluster, disconnect the cable by turning the attaching nut counterclockwise, snap the tachometer light socket out of the tachometer head and remove the two retaining nuts and bracket (Fig. 1).

TACHOMETER CABLE DRIVE

Refer to Group 23 for Tachometer Cable Drive Removal and Installation procedures.

TACHOMETER CORE

Disconnect the cable and core assembly from the tachometer and pull the tachometer core out of the casing. If the core is broken, disconnect the core and casing at the drive end and remove the lower part of the core.

To install, lubricate the core with lubricant C5AZ-19581-A (do not over lubricate). Install the core in the casing and attach the core and casing assembly.

Prior to installing the new core, check the casing for any sharp bends or kinks.

CABLE AND CORE ASSEMBLY

Disconnect the cable and core assembly from the tachometer head and from the cable drive end. Remove the retaining clips and remove the cable and core assembly.

To install, connect the tachometer cable and core assembly at the drive end and carefully route it to the tachometer head. **Be careful not to kink the cable during routing.** Install the retaining clips and check the operation of the tachometer.

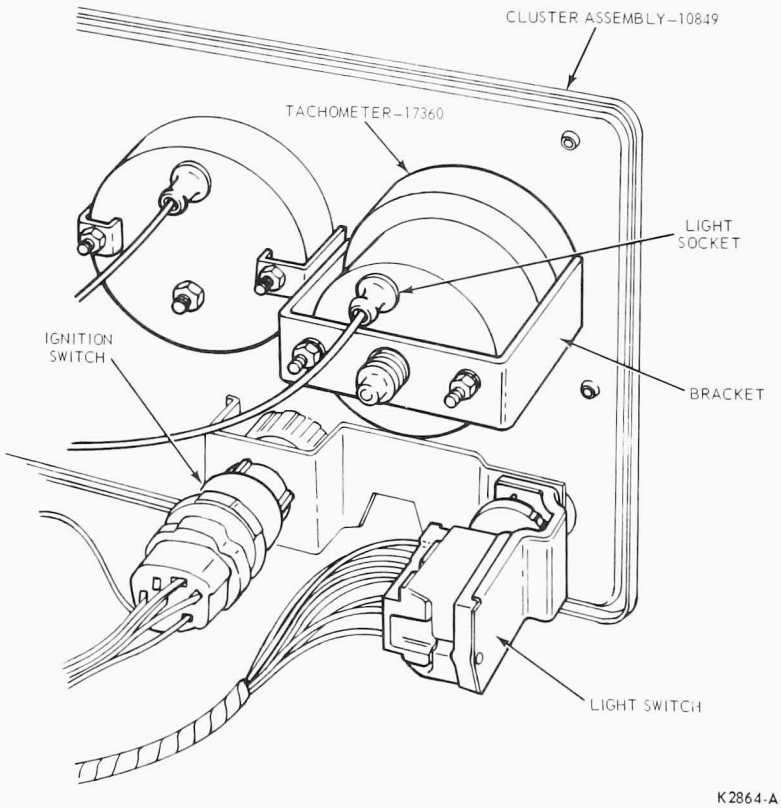

FIG. 1 Typical Tachometer Installation

PART 33-10 Charge Indicator—Light

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION		TESTING	
Charge Indicator Light System	10-01	Charge Indicator Light System	10-01
REMOVAL AND INSTALLATION			
Indicator Bulb	10-01		

DESCRIPTION AND OPERATION

CHARGE INDICATOR LIGHT SYSTEM

A red alternator charge indicator light is used on vehicles not equipped with an ammeter. This light glows when the battery is not receiving current from the charging system.

When the ignition switch contacts are closed (switch turned on) battery current flows through the charge indicator light and 15-ohm parallel resistor, and through the regulator voltage limiter contacts to the field, and the light comes on.

When the alternator builds up enough voltage to close the field relay contacts, full voltage is applied to the field and the charge indicator light goes out.

TESTING

CHARGE INDICATOR LIGHT SYSTEM

To test the charge indicator light, turn the ignition switch on with the engine stopped. The light should come on. If it does not, the bulb is burned out, or the wiring to the light is broken.

An open resistor wire in the alternator charging system wiring harness will usually cause the charge indicator light to stay on until the engine speed is increased to several thousand rpm. This effect will be noticed each time the engine is started. In some cases the light will not go out at all.

The charge indicator light may be tested with the use of a test light containing a trade number 67 or 1155 bulb.

Disconnect the regulator plug from the regulator. Turn the ignition switch to ACC position. Touch one test probe from the test light to the ignition terminal and the other to the regulator base. The test light will come on if the circuit is in proper working order. If the 15 ohm resistor or circuit is open, the indicator light will operate at full brightness and the test light will be out.

REMOVAL AND INSTALLATION

INDICATOR LIGHT

To remove the indicator bulb, reach up behind the instrument cluster, turn the bulb and socket assembly 1/4 turn counterclockwise and remove. To install, position the new bulb and socket assembly to the printed circuit and turn it clockwise 1/4 turn.

PART 33-12 Charge Indicator—Ammeter

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	12-01	TESTING	
REMOVAL AND INSTALLATION	12-01	Loop Type	12-01
		Shunt Type	12-01

DESCRIPTION AND OPERATION

AMMETER

The ammeter is a gauge which senses the direction and rate of flow of electrical current to or from the battery to indicate whether the battery is being charged or discharged. A Shunt-type ammeter is used in F-100 through F-350 cowl-chassis units, and in F-and B-500 through 750 units. Other trucks have loop-type ammeters. The ammeter is not adjustable and should be replaced if proved to be inoperative.

TESTING

AMMETER

To test the ammeter, turn the headlights on with engine stopped. The meter pointer should move toward the D or discharge scale. If no movement of the needle is observed, check the battery to circuit breaker wire connections (C-Series only). If the connections are tight, and the meter does not indicate either a charge or a discharge, the meter is inoperative. Replace the meter.

LOOP TYPE

If the meter pointer moves toward the C or charge scale when the headlights are turned ON, **the wire passes through the loop in the wrong direction, or the battery is reversed.** Feed the wire through the loop in the right direction to correct this condition, after checking first to make sure that the battery is not reversed.

SHUNT TYPE

If the meter pointer moves toward the C or charge scale when the headlights are turned ON, **the wire connections at the meter are reversed. Connect the wires to the ammeter correctly after checking first to make sure that the battery is not reversed.**

REMOVAL AND INSTALLATION

AMMETER

F-100 THROUGH F-350

Removal

1. Remove the trim cover from the instrument cluster assembly.
2. Remove the instrument cluster (four screws) and disconnect the speedometer cable from the speedometer head.
3. Remove the 14401 printed circuit plug from the cluster and remove the insulator from the alternator gauge terminal.
4. Disassemble the mask and lense assembly.
5. Remove the charge indicator ammeter (two nuts)

Installation

1. Install the charge indicator ammeter

(two nuts).
2. Assemble the mask and lens assembly.
3. Install the insulator to the alternator gauge terminal and the 14401 printed circuit plug to the cluster assembly.
4. Position the instrument cluster to the instrument panel, connect the speedometer cable and install the instrument cluster screws.
5. Install the trim cover.

BRONCO AND ECONOLINE

Remove the instrument cluster as outlined in Group 33, Part 50. Then, remove the trim cover, lens and mask from the front of the cluster by removing the retaining screws. Remove the ammeter retaining screws and remove the ammeter. To install, position the ammeter and install the retaining screws. Install the mask, the lens and trim cover to the front side of the cluster and install the retaining screws.

F-500 THROUGH F-750 AND C-SERIES

1. Remove the instrument cluster assembly from the instrument panel.
2. If equipped with a loop type ammeter, disconnect the lead from the junction block and pull the lead through the gauge loops. If equipped with a shunt type ammeter, disconnect the two wires at the gauge terminals.
3. Remove the retaining screws and remove the charge indicator gauge from the instrument cluster.
4. Position the charge indicator gauge to the instrument cluster and install the retaining screws.
5. If equipped with a loop type ammeter, feed the wire through the loops at the junction block. Be sure that the wire is not reversed in direction as it passes through the loops. If equipped with a shunt type ammeter, connect the two instrument cluster wires to the gauge terminals.
6. Install the instrument cluster assembly to the instrument panel.

W-SERIES AND L-SERIES LINE HAUL

Removal
1. Remove the battery cover and disconnect the batteries.
2. Remove the moulding from the top of the gauge panel secured by three screws.
3. Open the gauge panel. Disconnect leads, nuts and the bulb.
4. Remove the ammeter secured by clamps and nuts.

Installation
1. Position the ammeter in the panel and secure it with clamps and nuts.
2. Connect the leads. Install nuts and bulb.
3. Close the panel. Position the top moulding and secure it with retaining screws.
4. Connect the batteries and install the cover.
5. Check the operation of the ammeter.

PART 33-21 Fuel Indicating System

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	21-01	TESTING	
REMOVAL AND INSTALLATION		Fuel Gauge	21-02
Fuel Gauge	21-02	Fuel Sending Unit	21-02
Fuel Sending Unit	21-03		

DESCRIPTION AND OPERATION

FUEL GAUGE SYSTEM

The fuel indicating system consists of a sender unit located in the fuel tank and a fuel gauge mounted in the instrument cluster (Fig. 1).

The fuel gauge pointer is attached to a wire wound bi-metal strip and when heated by the flow of current controlled by the sender, produces the appropriate indication. When the current is low, there is little heating effect and the pointer moves a short distance. As the current increases, it produces a greater heating effect causing the pointer to move a proportionately greater distance.

The fuel level sending unit consists of a variable resistor, that is controlled by the action of an attached float in the fuel tank. When the fuel level is low, the sending unit resistance is high and restricts the flow of current to the fuel gauge. A high fuel level causes a low resistance in the sending unit and allows a higher current to flow to the fuel gauge.

Thus, if the fuel level is low, resistance in the sender is high and allows only a low current to flow through the gauge windings causing the pointer to move a short distance. If the fuel level is high, the resistance in the sender is low and allows a higher current to flow causing the pointer to move a greater distance.

The L-Series Line Haul model system does not have an instrument voltage regulator. It operates directly from battery voltage.

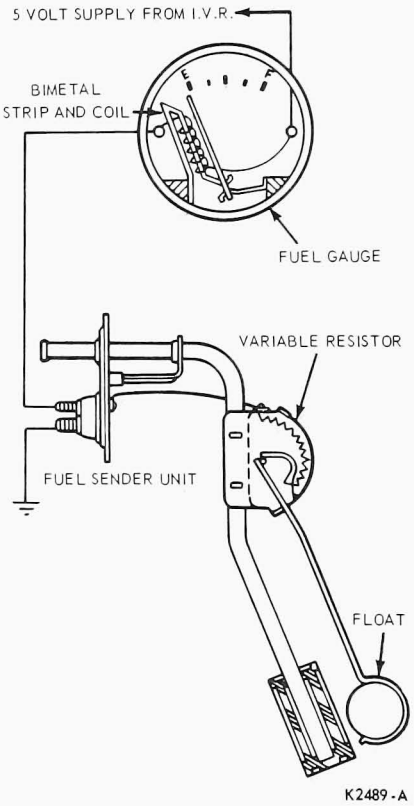

FIG. 1 Fuel Level Indicating System

TESTING

FUEL GAUGE

ALL EXCEPT L-SERIES LINE HAUL MODELS

Follow the instructions printed on the case of the Rotunda Fuel Gauge System Tester No. WRE 500-70. If a Rotunda Tester is not available, use the following procedure.

Disconnect the fuel gauge lead from the terminal at the sender unit and connect the lead of a 12-volt test light or the positive lead of a volt meter (20 volt scale) to the gauge lead that was disconnected from the sender unit. Connect the other test lead to a suitable ground. With the ignition switch in the ON position, a flashing light or fluctuating voltage will indicate that the instrument voltage regulator is good and that the gauge circuit is not interrupted.

If a pulsating voltage is shown but the gauge is not accurate, perform the calibration test.

If the light stays on or the voltage reading is steady, replace the I.V.R.

If no voltage is indicated by the voltmeter or test light, check the I.V.R. for proper ground and check for an open circuit in the I.V.R., the gauge windings, the printed circuit on Econoline and F-100-350, or the feed wire from the I.V.R. to the gauge on all other models.

Do not ground or spark either terminal of the instrument voltage regulator. This will burn out the dash wiring harness or the instrument voltage regulator or both.

L-SERIES LINE HAUL MODELS

Since L-Series Line Haul models do not have an instrument voltage regulator, the fuel gauge works directly off the 12-volt battery system and is tested in a different manner than fuel gauges on other vehicles.

The required test equipment consists of: a 33 ohm, 5 watt resistor to check gauge calibration for high readings; a 100 ohm, 2 watt resistor to check the calibration for mid-scale readings; and a 270, 1 watt resistor to check the calibration for low readings.

Disconnect the lead from the fuel gauge at the sender unit, connect the resistor between the gauge lead and ground, and turn on the ignition switch. With the 33 ohms, 5 watt resistor the gauge should read approximately **FULL**. With the 100 ohm, 2 watt resistor, the gauge pointer should approximate the mid-point on the scale. With the 270 ohm, 1 watt resistor, the reading should be approximately **EMPTY**.

If the gauge does not perform as indicated in this test, either the gauge or the wires connected to the gauge are damaged. If the gauge shows correct calibration, replace the sending unit.

SENDING UNIT

Drain or pump the fuel from the fuel tank. Disconnect the gauge lead at the sending unit and remove the sending unit from the tank. Using an ohmmeter, connect one lead to the metal housing of the sending unit and the other lead to the variable resistor terminal of the sending unit. The ohmmeter should read 8-12 ohms of resistance with the fuel sending unit float rod at the full end (up) of its travel and 60-86 ohms of resistance at the empty end (down). If the resistance is not within limits, replace the sending unit.

REMOVAL AND INSTALLATION

FUEL GAUGE

BRONCO AND ECONOLINE

Remove the instrument cluster as outlined in Group 33, Part 50. Then remove the trim cover, lens and mask from the front of the cluster by removing the retaining screws.

Remove the fuel gauge retaining screws and remove the fuel gauge.

To install, position the fuel gauge and install the retaining screws. Install the mask, the lens and trim cover to the front side of the cluster and install the retaining screws.

F-100 Through F-350

Remove the instrument cluster as outlined in this Group. Then, remove the lens and mask from the cluster. Remove the 2 nuts attaching the gauge to the cluster, and remove gauge. To install, reverse the removal procedure.

ALL OTHERS EXCEPT F-100 THROUGH F-350 AND W-SERIES

1. If necessary, disconnect the speedometer cable, remove the instrument cluster retaining screws and tilt the cluster toward the steering column. On a truck with air brakes, the line must be disconnected from the air pressure gauge. On a truck with a tachometer, the connections to the tachometer must be disconnected.
2. Disconnect the fuel gauge wires from the fuel gauge housing.
3. Remove the fuel gauge retaining screws and remove the fuel gauge assembly from the instrument cluster.
4. Position the fuel gauge assembly to the instrument cluster and install and tighten the retaining screws.
5. Connect the wires to the fuel gauge housing.
6. If removed, install the instrument cluster assembly to the instrument panel and connect the speedometer cable. Connect the tachometer and the air pressure gauge, if so equipped.

W-SERIES—ON INSTRUMENT PANEL

Removal

1. Remove the battery cover and disconnect the batteries.
2. Remove the moulding from the top of the gauge panel secured by two screws.
3. Open the gauge panel. Disconnect the two leads, two nuts and a bulb.
4. Remove two nuts and brackets retaining the fuel gauge to the panel and remove the gauge.

Installation

1. Position the new fuel gauge to the panel and secure with two brackets and nuts.
2. Install the bulb socket and bulb and connect the electrical leads.
3. Close the panel. Position the top moulding and secure it with two retaining screws.
4. Connect the batteries and install the cover.
5. Check the operation of the gauge.

SENDING UNIT

1. Remove the fuel from the fuel tank.
2. Disconnect the fuel gauge sending unit wire from the sending unit.
3. Loosen the hose clamp and disconnect the tank line at the sending unit.
4. Remove any dirt that has accumulated around the sending unit so that it will not enter the tank.
5. Turn the sending unit retaining ring counterclockwise and remove the unit, retaining ring, and mounting gasket.
6. Clean the fuel gauge sending unit mounting surface at the fuel tank.
7. Position the sending unit and a new mounting gasket on the fuel tank and secure it with the retaining ring.
8. Connect the sending unit wire and the fuel tank line.
9. Fill the tank with the fuel removed.
10. Check the fuel gauge operation and check for leaks.

PART 33-30 Oil Pressure Indicator—Light

DESCRIPTION AND OPERATION

SYSTEM OPERATION

A red indicator light glows when the oil pressure is below a safe value. The light should come on when the ignition switch is first turned to the R or run position. The indicator light should go out after the engine is started, indicating that the oil pressure has reached a safe value.

The light is connected between the oil pressure switch unit (mounted on the engine) and the coil terminal of the ignition switch (Fig. 1).

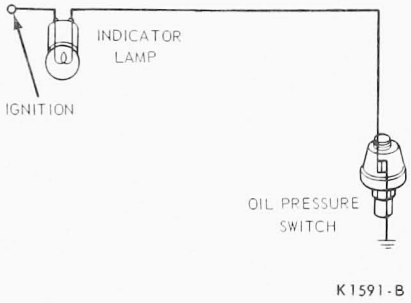

FIG. 1 Oil Pressure Indicator—Light System

TESTING

SYSTEM TESTING

To test the indicator light, turn on the ignition switch. Do not start the engine. The light should come on. Start the engine. The light should go out, indicating that the oil pressure has built up to a safe value.

To test the oil pressure switch on the engine, turn the ignition switch on with the engine not running. The indicator light should come on. If the indicator light does not come on, short the terminal of the oil pressure switch unit to ground. If the light now comes on, the oil pressure switch is inoperative, or not properly sealed to the engine. **Be sure to use electrically conductive sealer C3AZ-19554-B or Teflon tape (DOAZ-19554-C) on the mounting threads. If the light still does not come on, the bulb is burned out or the wires from the bulb to the ignition switch and oil pressure switch are worn or broken.**

REMOVAL AND INSTALLATION

SENDING UNIT SWITCH

The oil pressure sending units are mounted in different ways and locations. Figs. 2 and 3 are typical examples.

To remove the sending unit, disconnect the wire at the unit terminal and unscrew the unit from its mounting. Install the new sending unit, connect the wire to the unit terminal, and check the operation of the unit. **Be sure to use Teflon tape (DOAZ-19554-C), or electrically conductive water resistant sealer C3AZ-19554-B on the threads of the unit. The pressure switch type unit used with the indicator light system is not interchangeable with the variable resistance type unit used with gauge system. Refer to the Ford Truck Master Parts Catalog for proper parts usage. Installation of the wrong sending unit will result in an inoperative oil pressure indicating system and a damaged sending unit or gauge.**

INDICATOR LIGHT

To remove the indicator bulb, turn the bulb and socket assembly 1/4 turn counterclockwise and remove. To install, position the new bulb and socket assembly to the printed circuit and turn it clockwise 1/4 turn.

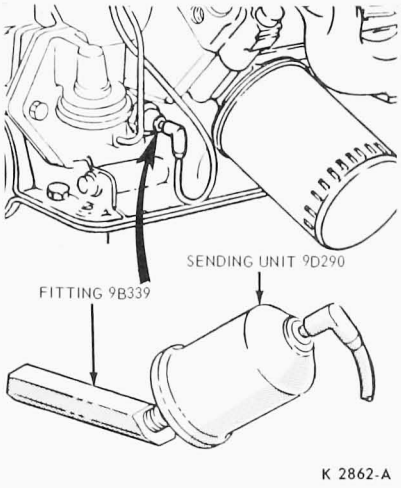

FIG. 2 Oil Pressure Sending Switch—8-Cylinder Typical

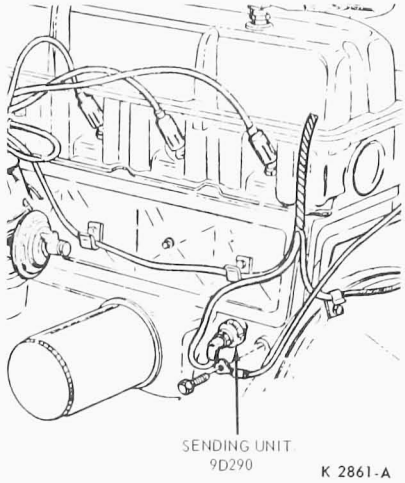

FIG. 3 Oil Pressure Sending Switch—6-cylinder Typical

PART 33-32 Oil Pressure Indicator Gauge

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION		TESTING	
Electrical Gauge System	32-01	Calibration Test	32-01
Pressure Gauge System	32-01	Gauge Bench Test	32-02
REMOVAL AND INSTALLATION		Sending Unit and Gauge	32-01
Gauge	32-03		
Sending Unit	32-02		

DESCRIPTION AND OPERATION

SYSTEM OPERATION

ELECTRICAL GAUGE SYSTEM

The oil pressure gauge indicating system consists of the instrument voltage regulator, an oil pressure indicating gauge and an oil pressure sending unit, all connected in series. The sending unit consists of a diaphragm, a contact and a variable resistor. The oil pressure causes the diaphragm to move the contact on the variable resistor thus controlling the flow of current through the gauge.

When the oil pressure is low, the resistance of the sending unit is high, thus restricting the flow of current through the gauge which moves the pointer only a short distance. As the oil pressure increases, the resistance of the sending unit decreases causing a proportionately increased flow of current and movement of the pointer.

PRESSURE GAUGE SYSTEM

The direct oil pressure indicating system consists of a oil pressure gauge mounted in the instrument cluster and a pressure tube connected at the pressure pick-up point on the engine. As the engine oil pressure increases, a Bourdon tube in the gauge deflects causing the pointer to move.

TESTING

ELECTRICAL GAUGE SYSTEM

SENDING UNIT AND GAUGE

Remove the oil pressure sender unit and temporarily attach a mechanical oil pressure gauge in its place. Operate the engine to determine the oil pressure. If the oil pressure indicated on the mechanical gauge is normal, the instrument panel gauge should also indicate within the normal band.

If the gauge does not indicate, make sure that the sender unit is properly sealed to the engine. **Apply electrically conductive sealer C3AZ-19554-B.** If the gauge still does not indicate, proceed as follows. Follow the instructions printed on the case of the Rotunda Tester No. WRE 500-70.

If a Tester is not available, use the following procedure.

Disconnect the oil gauge lead from the terminal at the sender unit and connect the lead of a 12-volt test light or the positive lead of a volt meter (20 volt scale) to the gauge lead that was disconnected from the sender unit (Fig. 1). Connect the other test lead to a suitable ground. With the ignition switch in the ON or ACC position, a flashing light or fluctuating voltage will indicate that the instrument voltage regulator is good and that the gauge circuit is not interrupted.

If a pulsating voltage is shown but the gauge is not accurate, perform the calibration test.

If the light stays on or the voltage reading is steady, replace the I.V.R.

If no voltage is indicated by the voltmeter or test light, check the I.V.R. for proper ground and check for an open circuit in the I.V.R., the gauge windings, the printed circuit on Econoline and F-100-350, or the feed wire from the IV.R. to the gauge on all other models.

Do not ground or spark either terminal of the instrument voltage regulator. This will damage the dash wiring harness or the instrument voltage regulator or both.

CALIBRATION TEST

When the instrument voltage regulator or one of the gauges (oil, temperature, fuel) is suspected of being out of calibration, having a fluctuating movement or a high or low reading, both the gauge and the instrument

voltage regulator must be tested simultaneously. This test is done in the vehicle.

The required test equipment consists of a 10 ohm, 5 watt resistor to check the gauge calibration for correct high readings, and a 75 ohm, 1 watt resistor to check the calibration for low readings.

Disconnect the lead from the gauge to be tested at the appropriate sender unit, connect the resistor between the gauge lead and gound (Fig. 1), and turn on the ignition switch. With the 10 ohm resistor, the gauge should show a high reading. With the 75 ohm resistor, the gauge should show a low reading.

If the gauge does not perform as indicated, replace the instrument voltage regulator and retest to determine if the gauge is causing the trouble. If the gauge now reads correctly, the trouble has been eliminated. If the gauge is still out of calibration, it must be replaced.

GAUGE BENCH TEST FOR OPEN WINDINGS

To test a fuel, oil, or temperature gauge for open windings, remove the gauge from the vehicle as outlined in the appropriate car line Removal and Installation Section in this Part. Connect the gauge to an ohmmeter and read the resistance. An upward movement of the needle from 10 toward 14 ohms is normal because the current increases the temperature of the gauge coil (windings). If the ohmmeter reads below 10 ohms or above 14 ohms, replace the gauge.

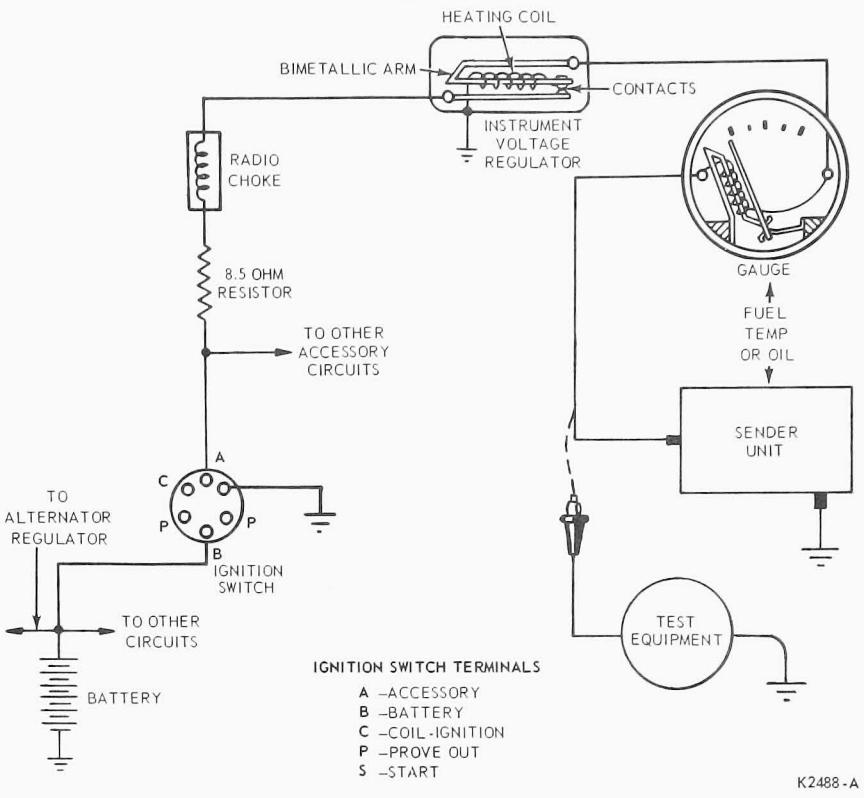

FIG. 1 Instrument Voltage Regulator and Gauge System Test

REMOVAL AND INSTALLATION

SENDING UNIT

The oil pressure sending units are mounted in different ways and locations. Figs. 2 and 3 are typical examples.

To remove the sending unit, disconnect the wire at the unit terminal and unscrew the unit from its mounting. Install the new sending unit, connect the wire to the unit terminal, and check the operation of the unit. **Be sure to use electrically conductive water resistant sealer C3AZ-19554-B on the threads of the unit. The pressure switch type unit used with the indicator light system is not interchangeable with the variable resistance type unit used with gauge system. Refer to the Ford Truck Master Parts Catalog for proper parts usage. Installation of the wrong sending unit will result in an inoperative oil pressure indicating system and a damaged sending unit or gauge.**

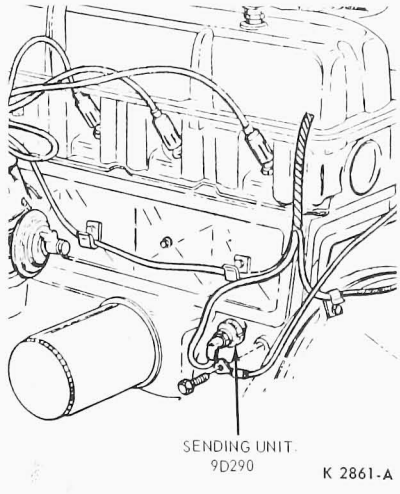

FIG. 2 Oil Pressure Sending Unit—6-Cylinder Typical

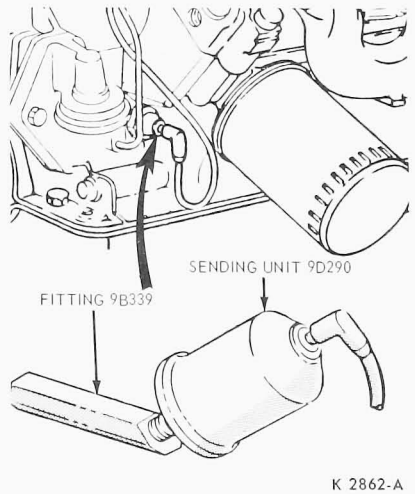

FIG. 3 Oil Pressure Sending Unit—8-Cylinder Typical

OIL PRESSURE GAUGE

BRONCO, F-100 THROUGH F-350 AND ECONOLINE

Remove the instrument cluster as outlined in Group 33, Part 50. Then remove the trim cover, mask and lens from the front of the cluster by removing the retaining screws. Remove the oil pressure retaining screws and remove the gauge. To install, position the oil pressure gauge and install the retaining screws. Install the mask, lens and trim cover to the front side of the cluster and install the retaining screws.

F-100 THROUGH F-350

Remove the instrument cluster as outlined in Part 33-12. Then, remove the lens and mask from the cluster. Then, remove the 2 nuts attaching the gauge to the cluster, and remove gauge. To install, reverse the the removal procedure.

ALL OTHERS EXCEPT W-SERIES, L-SERIES F-100 THROUGH F-350 AND CITY DELIVERY MODELS

Remove the instrument cluster as outlined in Group 33, Part 51. Disconnect the leads from the oil pressure gauge. Remove the retaining screws and remove the gauge. To install, position the gauge to the cluster and install the retaining screws. Connect the leads to the gauge and install the cluster.

W-SERIES AND L-SERIES LINE HAUL

Removal

1. Remove the battery cover and disconnect the batteries.
2. Remove the moulding from the top of the gauge panel secured by two screws.
3. Open the gauge panel. Disconnect the lead and bulb.
4. Remove the gauge secured by two nuts and a bracket.

Installation

1. Position the gauge in the panel and secure it with a bracket and nuts.
2. Install the bulb and connect the lead.
3. Close the panel. Position the top moulding and secure it with two retaining screws.
4. Connect the batteries and install the cover.
5. Check the operation of the gauge.

DESCRIPTION AND OPERATION

TEMPERATURE GAUGE SYSTEM

ALL EXCEPT W-SERIES AND L-SERIES, LINE HAUL TRUCKS

The temperature indicating system consists of a sending unit mounted in the cylinder head, and a temperature gauge mounted on the instrument panel. When the engine temperature is low, the resistance of the sending unit is high, thus restricting the flow of current through the gauge which moves the pointer only a short distance. As the temperature of the engine increases, the resistance of the sending unit decreases causing a proportionately increased flow of current and movement of the pointer.

W-SERIES AND L-SERIES, LINE HAUL TRUCKS

These trucks use a combination temperature sending unit and gauge assembly which operates on the capillary tube, direct action gauge principle rather than electrically. A temperature bulb (sending unit) filled with ether is threaded into the engine block. A capillary tube (cable) connects the temperature bulb in the engine to a curved (Bourdon) tube in the gauge at the instrument cluster. The Bourdon tube is connected to the gauge pointer. As engine temperature rises, the ether expands causing the curved Bourdon tube to straighten out and thus move the pointer to a higher reading. As the engine cools, the ether contracts causing the Bourdon tube to resume its curved position and thus move the pointer to a lower reading.

TESTING

GAUGE SYSTEM

ALL EXCEPT W-SERIES AND L-SERIES, LINE HAUL TRUCKS

Start the engine and allow it to run until a thermometer placed in the coolant at the radiator filler cap reads a minimum of 180 degrees F. The gauge in the instrument panel should indicate within the normal band.

If the gauge does not indicate, use of the Gauge System Tester No. WRE 500-70. If a Tester is not available, use the following procedure.

Disconnect the gauge lead from the terminal at the sender unit. Connect the lead of a 12 volt test light or the positive lead of a voltmeter (20 volt scale) to the gauge lead that was disconnected from the sender unit (Fig. 1). Connect the other test lead to a suitable ground. With the ignition switch in the ON or ACC position, a flashing light or fluctuating voltage will indicate that the instrument voltage regulator is good and that the gauge circuit is not interrupted.

If a pulsating voltage is shown but the gauge is not accurate, perform the calibration test.

If the light stays on or the voltage reading is steady, replace the I.V.R.

If no voltage is indicated by the voltmeter or test light, check the I.V.R. for proper ground and check for an open circuit in the I.V.R., the gauge windings or the printed circuit.

Do not ground or spark either terminal of the instrument voltage regulator. This will damage the dash wiring harness or the instrument voltage regulator or both.

CALIBRATION TEST

When the instrument voltage regulator or one of the gauges (oil, temperature, fuel) is suspected of being out of calibration, having a fluctuating movement or a high or low reading, both the gauge and the instrument voltage regulator must be tested simultaneously. This test is done on the vehicle.

The required test equipment consists of a Rotunda Tester No. WRE 500-70 or a 10 ohm resistor to check the gauge calibration for correct high readings, and a 73 ohm resistor to check the calibration for low readings.

Disconnect the lead from the gauge at the sender unit, connect the resistor between the gauge lead and ground (Fig. 1), and turn on the ignition switch. With the 10 ohm registor, the gauge should show a high reading. With the 73 ohm resistor, the gauge should show a low reading.

If the gauge does not perform as indicated, replace the instrument voltage regulator and retest to determine if the gauge is causing the

trouble. If the gauge now reads correctly, the trouble has been eliminated. If the gauge is still out of calibration, the gauge is damaged and must be replaced.

GAUGE BENCH TEST FOR OPEN WINDINGS

To test the gauge for open windings, remove the gauge from the vehicle. Connect the gauge to an ohmmeter and read the resistance. An upward movement of the needle from 10 toward 14 ohms is normal because the current increases, the temperature of the gauge coil (windings). If the ohmmeter reads below 10 ohms or above 14 ohms, replace the gauge.

W-SERIES AND L-SERIES, LINE HAUL TRUCKS

Start the engine and allow it to run until it has reached normal operating temperature. Place a thermometer in the coolant at the radiator filler cap. The thermometer should read close to the temperature range of the coolant thermostat that is being used. The gauge in the instrument panel should indicate within the normal band.

If the gauge does not indicate, the ether has escaped through a leak in the temperature bulb, in the capillary tube, or in the Bourdon tube at the gauge. Replace the bulb, tube and gauge as an assembly.

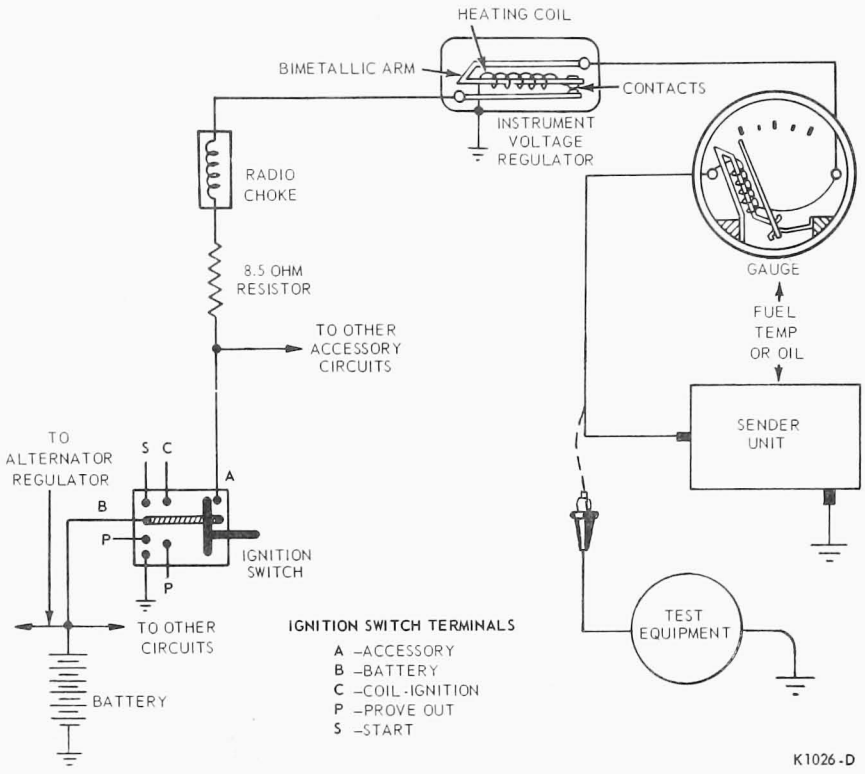

FIG. 1 Instrument Voltage Regulator and Temperature Gauge Test

REMOVAL AND INSTALLATION

TEMPERATURE SENDING UNIT

ALL EXCEPT W-SERIES AND L-SERIES, LINE HAUL TRUCKS

1. Disconnect the temperature sending unit wire at the sending unit.
2. Prepare the new temperature sending unit for installation by applying a small amount of electrically conductive sealer C3AZ-19554-B to the threads.
3. Remove the temperature sending unit from the cylinder head and immediately install the new temperature sending unit.
4. Connect the wire to the temperature sending unit.
5. Start the engine and check the sending unit operation.

TEMPERATURE GAUGE

ECONOLINE

1. If necessary, disconnect the speedometer cable, remove the instrument cluster retaining screws and tilt the cluster toward the steering column. On a truck with air brakes, the line must be disconnected from the air pressure gauge. On a truck with a tachometer, the connections to the tachometer must be disconnected.
2. Disconnect the temperature gauge wiring from the temperature gauge housing.
3. Remove the temperature gauge retaining screws and remove the temperature gauge assembly from the instrument cluster.
4. Position the temperature gauge assembly to the instrument cluster and install and tighten the retaining screws.
5. Connect the wires to the temperature gauge housing.
6. If removed, install the instrument cluster to the instrument panel and connect the speedometer cable. Connect the tachometer and the air pressure gauge if so equipped.

F-100 Through F-350

Remove the instrument cluster as outlined in this Group. Then, remove the lens and mask from the cluster. Then, remove the 2 nuts attaching the gauge to the cluster, and remove gauge.

To install, reverse the removal procedure.

W-SERIES

Removal

1. Remove the battery cover and disconnect the batteries.
2. Remove the moulding from the top of the gauge panel secured by two screws.
3. Open the gauge panel. Disconnect the tube assembly and a bulb.
4. Remove two nuts and brackets retaining the temperature gauge to the panel and remove the gauge.

Installation

1. Position the new temperature gauge to the panel and secure with two brackets and nuts.
2. Install the bulb socket and bulb and connect the tube assembly.
3. Close the panel. Position the top moulding and secure it with two retaining screws.
4. Connect the batteries and install the cover.
5. Check the operation of the gauge.

BRONCO

Disconnect the battery ground cable and pull the instrument cluster away from the panel far enough to gain access to the cluster back. Disconnect the wires from the gauge. Then, remove the instrument cluster plate, lens and mask. Remove the gauge retaining screws, and remove the gauge.

To install, fit the replacement gauge in position in the cluster and install the retaining screws. Install the instrument cluster plate, lens and mask. Connect the wires to the gauge terminals. Install the cluster and connect the battery ground cable. Test the gauge for proper operation.

TEMPERATURE SENDING UNIT AND GAUGE COMBINATION

W-SERIES AND L-SERIES, LINE HAUL TRUCKS

Removal

1. Disconnect the battery.
2. Drain the cooling system.
3. Tilt the cab.
4. Disconnect the temperature cable and bulb from the engine.
5. Remove the bolt and clip retaining the temperature cable through the grille opening.
6. Remove the bolt and clip retaining the cable to the block and feed the cable back to the floor pan.
7. Lower the cab.
8. Remove the grommet and retainer from the floor pan by removing two screws and pull the cable and bulb through the floor pan and into the cab.
9. Remove the moulding at the top of the gauge panel by removing two screws.
10. Open the gauge panel and disconnect the light. Remove two nuts retaining the gauge and bracket to the panel. Remove the gauge, cable and bulb assembly by feeding the bulb and cable up through the instrument panel and out through the gauge panel.

Installation

1. Route the cable and bulb through the gauge panel, instrument panel and down the side of the steering column. Position the gauge and bracket to the panel and install the two retaining screws.
2. Close the gauge panel. Position the top moulding and secure with two retaining screws.
3. Route the cable and bulb through the floor pan and to the engine.
4. Raise the cab.
5. Install the bolt and clip retaining the cable in front of the cab through the grille opening. Install the clip retaining the cable near the engine.
6. Apply sealer to the new assembly and install it into the block.
7. Lower the cab.
8. Install the grommet and retainer in the floor pan and secure it with two screws.
9. Fill the cooling system.
10. Connect the battery and install the battery cover.
11. Start the engine and check the new gauge operation.

PART 33-51 Instrument Cluster and Printed Circuit

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION		REMOVAL AND INSTALLATION - Cont.	
Instrument Cluster	51-01	Printed Circuit	51-03
Instrument Voltage Regulator	51-03		

REMOVAL AND INSTALLATION

CLUSTER ASSEMBLY

BRONCO

Removal

1. Disconnect the battery ground cable and disconnect the speedometer cable from the speedometer head.
2. Remove the screws retaining the instrument cluster assembly to the instrument panel.
3. Remove the cluster from behind the instrument panel. Disconnect the speedometer cable at the speedometer head.
4. Disconnect the feed wires to the instruments and the instrument voltage regulator and remove the light sockets from the cluster back, noting the positions of each. Remove the two clips that retain the wiring harness to the cluster back (1 screw each) and pull the harness away from the cluster. Remove the instrument cluster assembly (Fig. 1).

Installation

1. Mount the wiring harness to the lower edge of the cluster back by installing the two retaining clips (1 screw each).
2. Connect the instrument voltage regulator and the instrument wires to the cluster assembly and install the light sockets. **Be sure that the black-yellow stripe wire is routed correctly through the ammeter loop of the charge indicator to prevent reversed gauge indications.**
3. Connect the speedometer cable and tighten the nut.
4. Carefully move the instrument cluster into position from behind the instrument panel, guiding all wiring and cables into position to prevent damage. **Be careful not to kink the speedometer cable.**
5. Install the screws retaining the instrument cluster to the instrument panel.
6. Connect the battery ground cable and check the operation of all gauges, lights and signals.

ECONOLINE

Disconnect the battery ground cable. From the front of the cluster, remove the screws that retain the cluster to the instrument panel, and position the cluster part way out of the panel for access to the back of the cluster. At the back of the cluster, disconnect the speedometer cable from the head and disconnect the multiple (feed) plug from the printed circuit. Disconnect the wire from the flasher unit at the upper left hand corner of the cluster and remove the cluster assembly from the vehicle (Fig. 2).

To install, hold the cluster near its opening in the instrument panel and

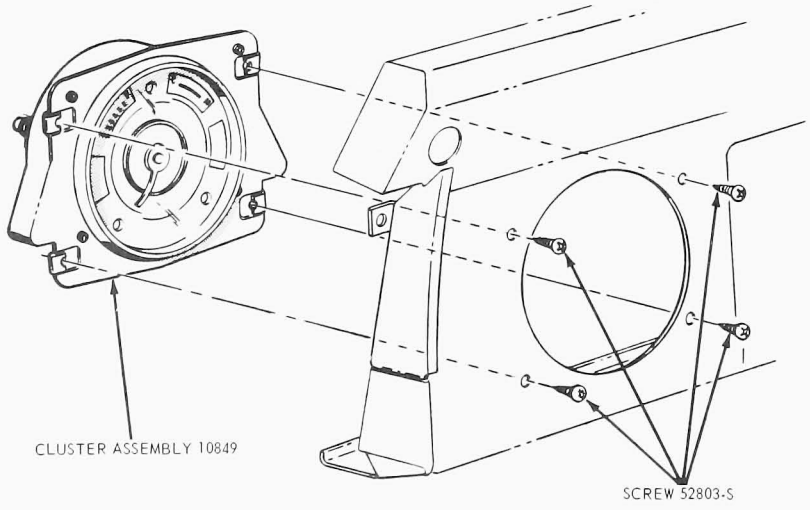

FIG. 1 Instrument Cluster—Bronco

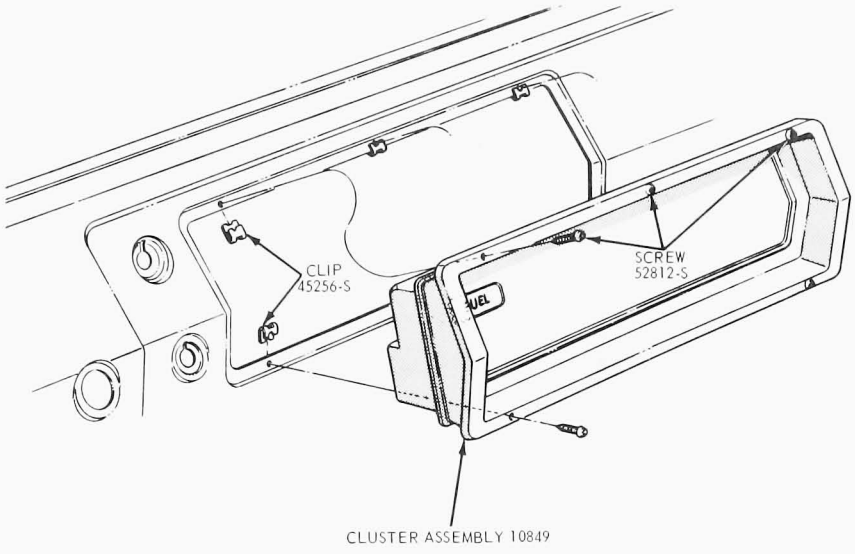

FIG. 2 Instrument Cluster—Econoline

connect: the wire to the flasher unit at the upper left hand corner of the cluster; the multiple feed plug to the printed circuit; and the speedometer cable to the head. Position the cluster to the instrument panel and install the retaining screws.

F-100 THROUGH F-350

Removal

1. Disconnect the battery ground cable.
2. Pull the radio knobs off the radio shafts (if so equipped).
3. Remove the fuel gauge switch knob (if so equipped), heater control knobs and wiper-washer knob. Use a hook tool to release each knob lock tab.
4. Remove the knob and shaft from the lights switch.
5. Remove one nut and washer from each radio control shaft, and remove the radio bezel.
6. Remove the cluster bezel (Fig. 4). The attaching screws are located as follows: 4 screws along top of bezel; one screw between the lights and wiper-washer switch; and 2 screws below the radio. Then, disconnect the A/C duct (if so equipped), and illumination light from the bezel. The illumination light is located

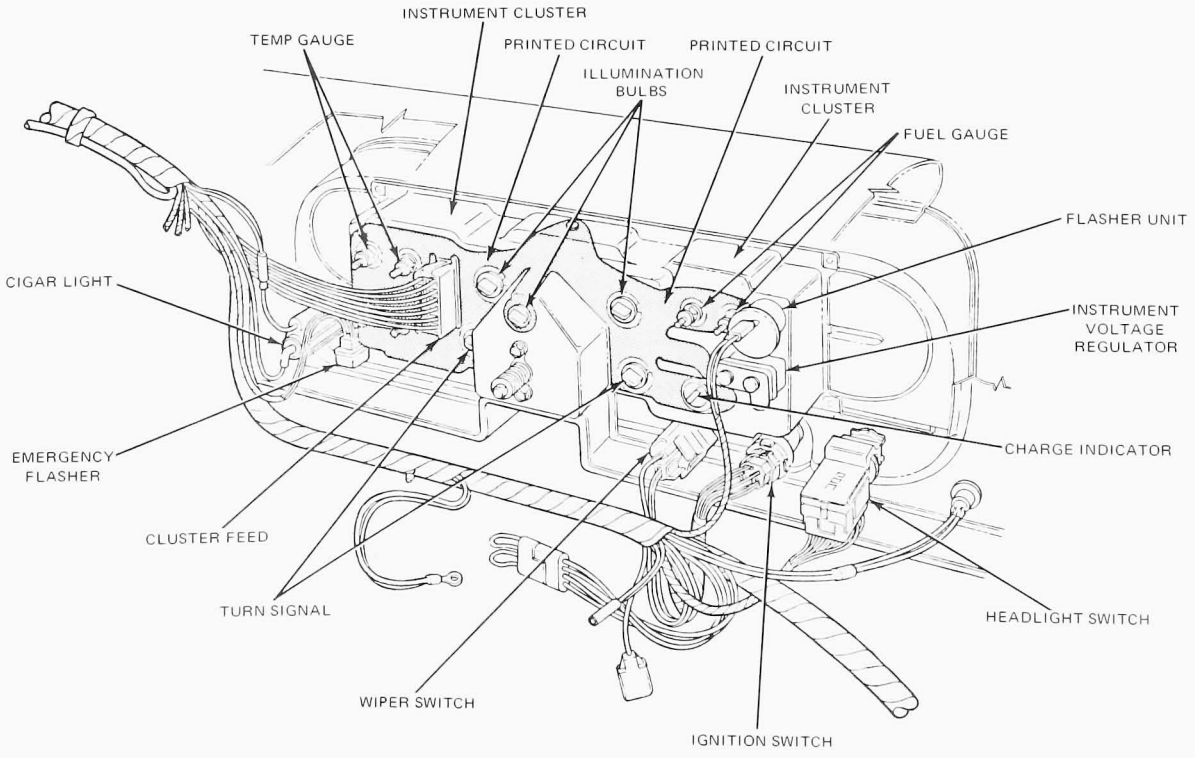

FIG. 3 Instrument Cluster-Back View—Econoline

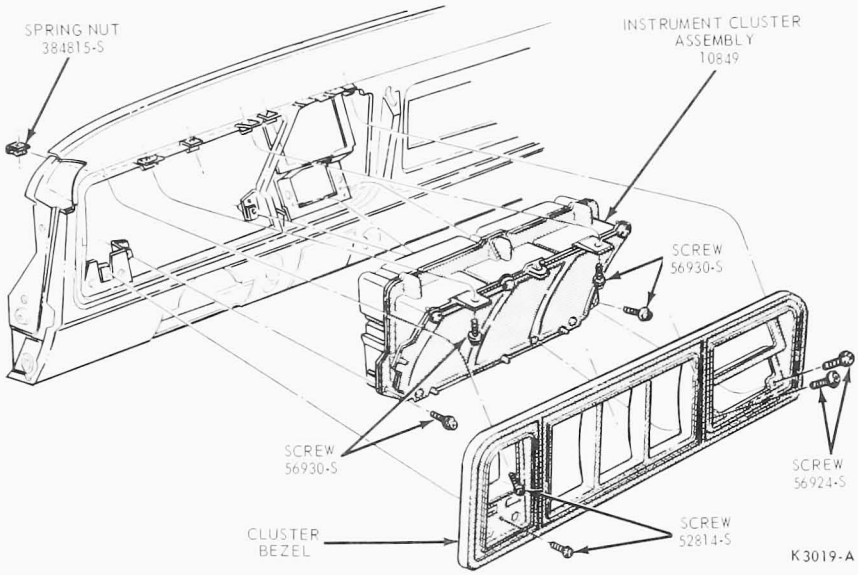

FIG. 4 Instrument Cluster—F-100-F-350

between the lights and wiper-washer switches.

7. Remove four cluster attaching screws, disconnect the speedometer cable and wire connector from the printed circuit, and remove the cluster (Figs. 5 and 6).

Installation

1. Position cluster to opening and connect the multiple connector and the speedometer cable. Connect the A/C illumination light (if so equipped) and install the four cluster retaining screws.
2. Install the cluster bezel.
3. Install the radio bezel (if so equipped).
4. Install the light switch knob and shaft.
5. Install the heater control knobs and the wiper-washer control knobs.
6. Install the radio knobs, (if so equipped).
7. Connect the battery cable.

ALL EXCEPT BRONCO, ECONOLINE AND F-100 THROUGH F-350

Removal

1. Disconnect the battery ground cable.
2. Disconnect the speedometer cable at the speedometer head.
3. Remove the screws retaining the instrument cluster assembly to the instrument panel and lift the cluster out at the front of the panel.
4. Disconnect the instrument wires, remove the light sockets and remove the cluster assembly. On a truck with air brakes, the line must be disconnected from the air pressure gauge. On a truck with a tachometer, the connections to the tachometer must be disconnected.

Installation

1. Position the instrument cluster assembly to the instrument panel, connect the instrument wires, and install the light sockets. Connect the tachometer and the air pressure line if so equipped.
2. Make certain that all wiring is moved away from the instrument panel opening. Install the instrument cluster assembly to the instrument panel with the retaining screws.
3. Connect the speedometer cable and the battery ground cable. **Be careful not to kink the speedometer cable.**
4. Check the operation of all gauges, lights and signals.

In some vehicles, removal may be made easier by first disconnecting the speedometer cable, removing the instrument cluster retaining screws, and tilting the cluster toward the steering column.

INSTRUMENT VOLTAGE REGULATOR AND PRINTED CIRCUIT

Remove the instrument cluster from the instrument panel as described in this Section. Disconnect (snap off) the printed circuit connector buttons from the voltage regulator. Remove the voltage regulator. Remove the voltage regulator from the cluster (1 retaining screw).

After removing the voltage regulator, remove the four gauge retaining nuts and the seven light bulbs, all of which hold the printed circuit to the back of the cluster. Remove the printed circuit from the cluster.

When installing the printed circuit, carefully position it to the back of the cluster and engage it to the plastic locating dowel.

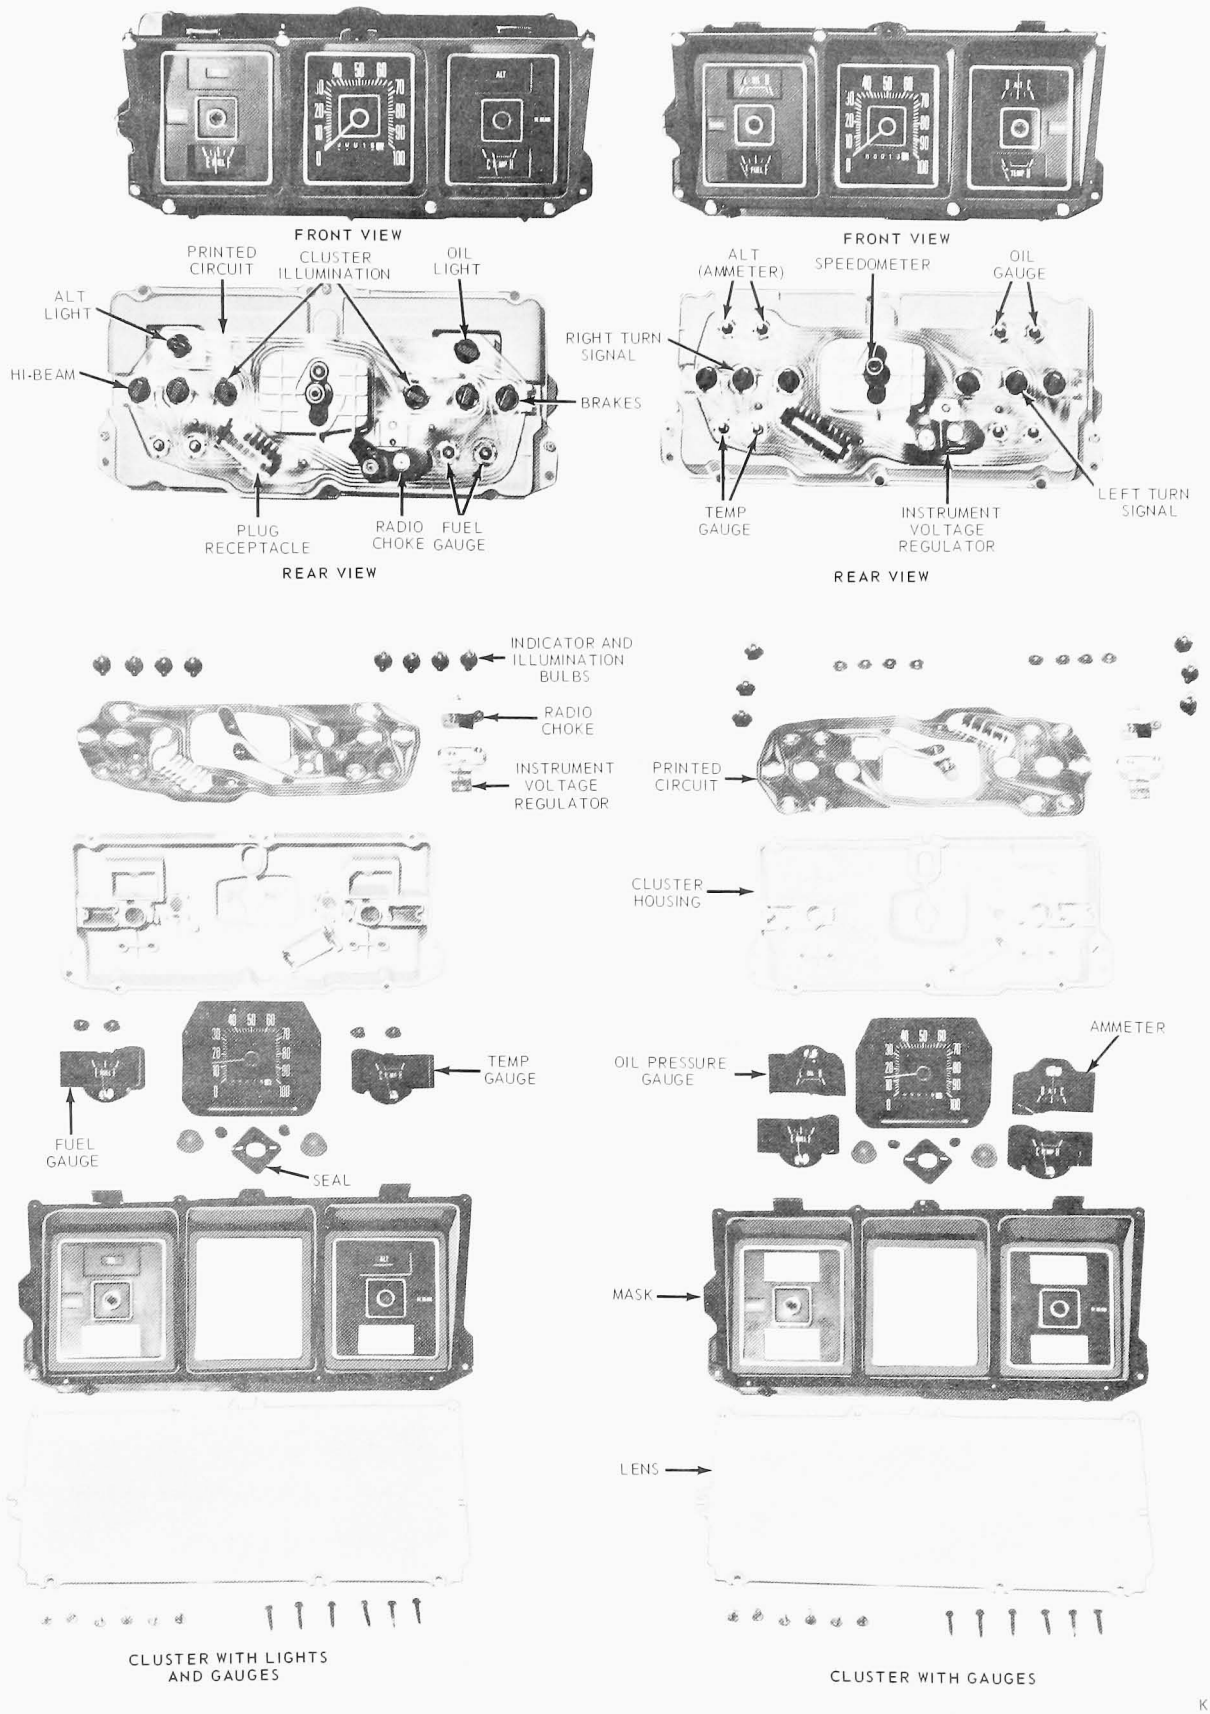

FIG. 5 Instrument Cluster Disassembled—F-100-F-350

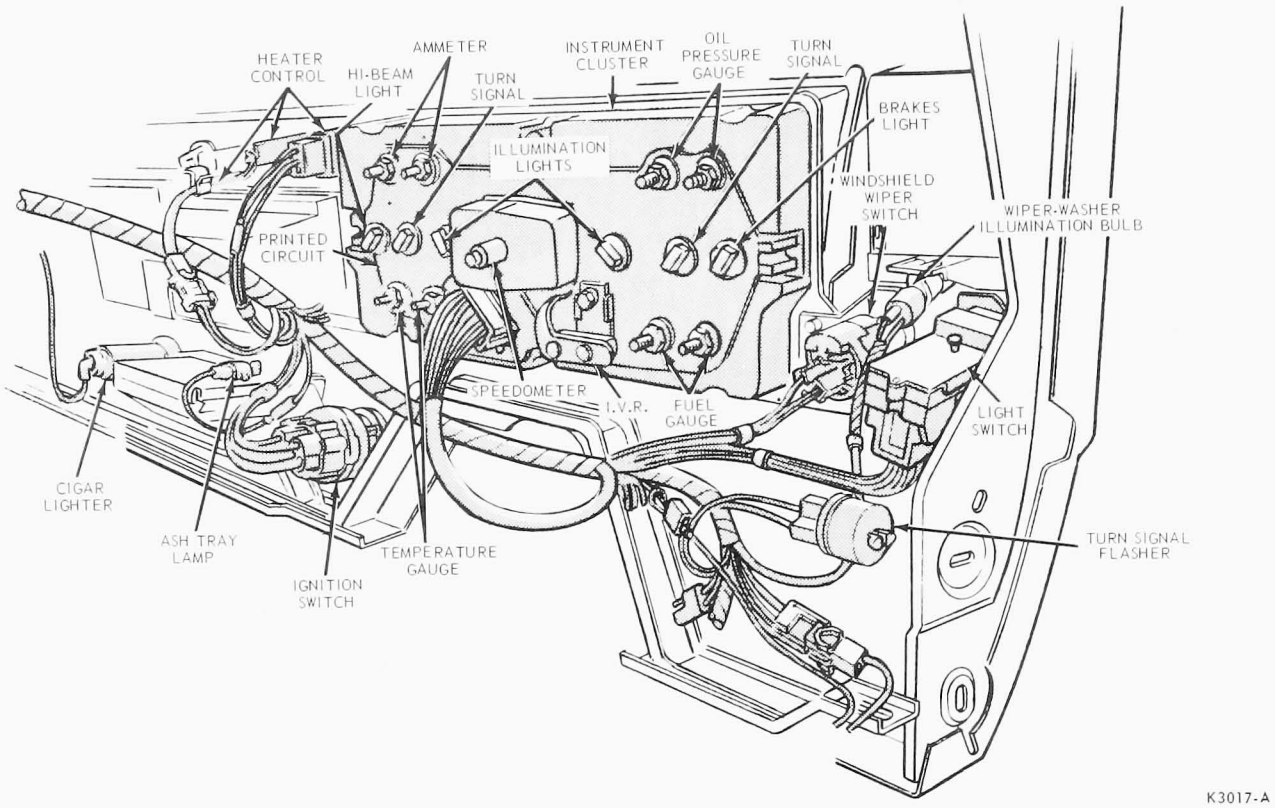

FIG. 6 Instrument Cluster Rear View—F-100-F-350

PART 33-71 Ignition Switch

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION	71-02	TESTING	71-01

TESTING

IGNITION SWITCH

To test the continuity of the ignition switch, remove the switch from the vehicle. Insert the ignition key in the switch. **Do not use anything but the key to actuate the switch to the various positions because of possible damage to the switch.** Using a self-powered test light or ohmmeter, check the continuity through the switch as illustrated in Fig. 1. If the switch **does not meet all** of the continuity tests, the switch should be replaced.

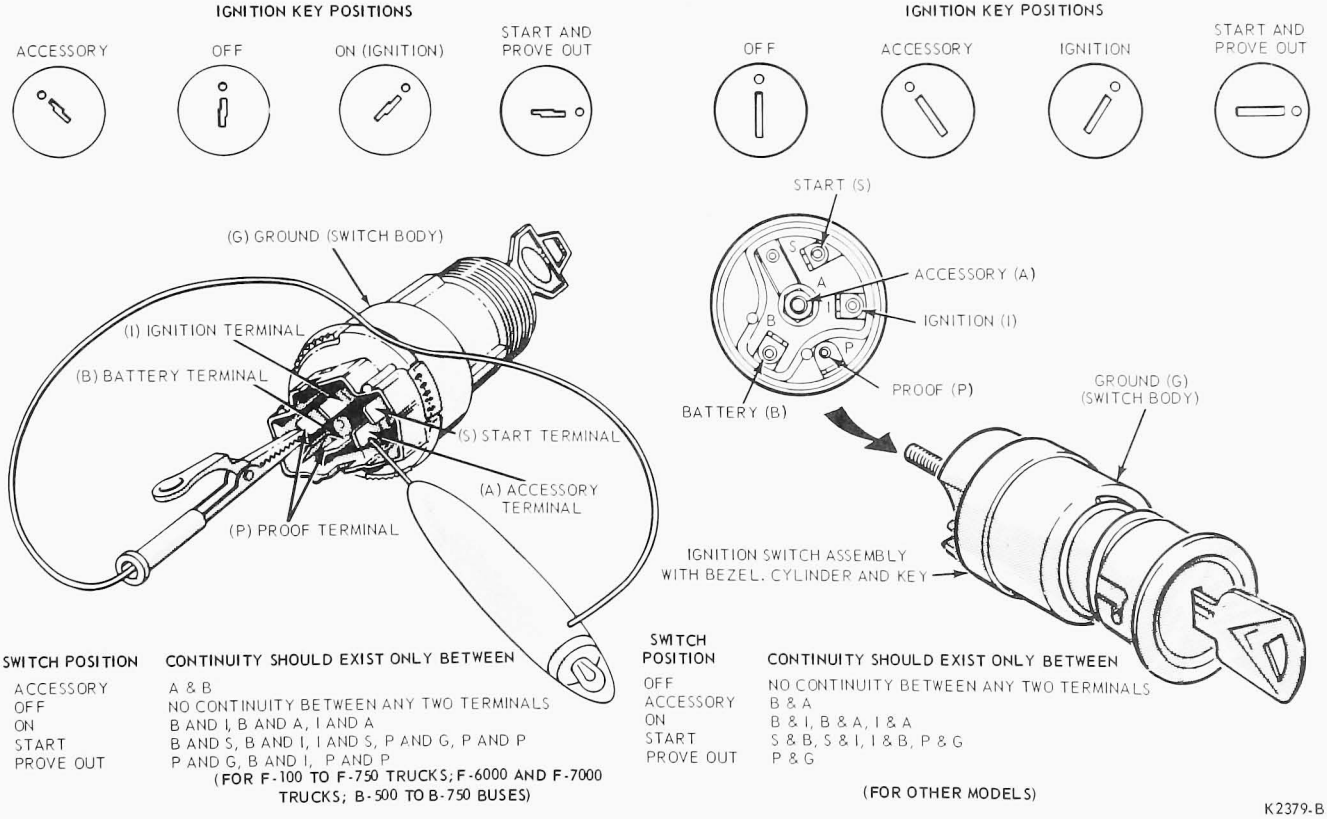

FIG. 1 Ignition Switch Continuity Test

REMOVAL AND INSTALLATION

IGNITION SWITCH

BRONCO, P-350-500

Removal

1. Disconnect the battery ground cable from the battery.
2. Turn the ignition key to the accessory position. Slightly depress the release pin in the face of the lock cylinder (Fig. 2), turn the key counterclockwise, and pull the key and lock cylinder out of the switch assembly. If only the lock cylinder is to be replaced, proceed to step 4 under Installation.
3. From under the instrument panel press in on the rear of the switch 1/8 turn counterclockwise (as viewed from the terminal end). Remove the bezel and switch. On Bronco and P-Series trucks also remove the retainer and spring.
4. Remove the nut from the back of the ignition switch. Remove the accessory and gauge feed wires from the accessory terminal of the switch. Pull off the insulated plug from the rear of the switch.

Installation

1. If a new ignition switch as well as the lock cylinder is to be installed, insert a screwdriver into the lock opening of the ignition switch and turn the slot in the switch to a full counterclockwise position.
2. Connect the insulated plug with wires to the back of the ignition switch. Position the accessory and gauge wires onto the ignition switch stud and install the retaining nut.
3. Place the bezel and switch in the switch opening, press the switch toward the instrument panel, and rotate it 1/8 turn to lock it in position.

Position the spring and retainer on the switch with open face of the retainer away from the switch. Place the switch to the switch opening. Press the switch toward the instrument panel and install the bezel.

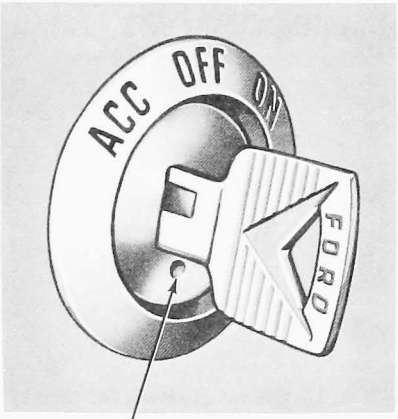

FIG. 2 Ignition Switch Removal

4. If a new lock cylinder is to be installed, insert the key in the cylinder and turn the key to the accessory position. Place the lock and key in the ignition switch, depress and release pin slight (Fig. 2), and turn the key counterclockwise. Push the new lock cylinder into the switch. Turn the key to check the lock cylinder operation.
5. Connect the battery cable and check the ignition switch operation.

ECONOLINE, F-100-350 SERIES AND BUSES

Removal

1. Disconnect the battery ground cable.
2. Insert the ignition key in the switch. Turn the key to the accessory position and insert a wire pin in the hole on the ignition switch. Slightly depress the pin while turning the key counterclockwise past the accessory position; this will release the lock cylinder from the switch assembly. Pull the lock cylinder from the switch with the key. If only the lock cylinder is to be replaced proceed to step 3 of the installation procedure.
3. Remove the bezel nut retaining the switch to the instrument panel and lower the switch.
4. Depress the tabs securing the multiple connector to the rear of the ignition switch with a modified tool 18918-A (Fig. 3). The modification of the tool consists of grinding the inside of the tool jaws to allow clearance around the rear of the switch. Pull the multiple connector from the switch and remove the switch.

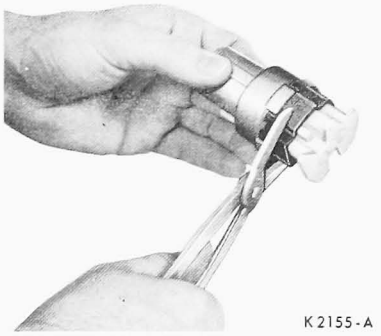

FIG. 3 Ignition Switch Connector Removal

Installation

1. Depress the tabs on the multiple connector and plug the connector into the switch assembly, being sure that the tabs lock in place.
2. Position the switch to the instrument panel and install the bezel nut.
3. Insert the key in the lock cylinder and turn the key to the accessory position. Place the cylinder and key in the switch. Push the cylinder into the switch until it is fully seated, then turn the key to the lock position. Turn the key to check the operation of the lock cylinder.
4. Connect the battery ground cable to the battery and check the operation of the switch assembly.

REMOVAL AND INSTALLATION

BRONCO

Starting at the left headlight, the 14401 harness runs back along the left fender apron and through a grommet at the left side of the dash panel into the passenger compartment. From the left grommet, the harness runs along the lower edge of the instrument panel to a similar grommet on the right side of the dash. Through the right grommet, the harness returns to the engine compartment, runs along the right fender apron and terminates at the right headlight and the 14305 harness connector. Thus the 14401 wiring harness combines three main wiring harnesses in one (instrument panel-to-dash, left side dash-to-headlight junction, and right side dash-to-headlight junction).

Removal

1. Disconnect the battery ground cable.
2. Starting at the left side forward end of the engine compartment, disconnect the harness connectors to the left headlight, parking light, and side marker light. Disconnect the harness wire at the horn.
3. Working from front to rear, remove the harness from the retaining straps along the left fender apron.
4. Disconnect the two harness multiple connectors and one bullet connector at the rear of the left wheel housing.
5. Disengage the harness grommet from the hole in the left side of the dash; and pull the harness through the grommet hole into the passenger compartment.
6. Disconnect the harness multiple plugs at the dimmer switch and at the steering column connector. Disconnect the harness push-on connectors at the stop light switch and the harness connectors to the radio, heater and map light wires.
7. The harness branch loom that goes through the grommet at the center of the dash panel has to be disconnected from the engine side of the dash. Disconnect the multiple plug and (with 8-cylinder engine) the bullet connector. Disengage the grommet from the dash and push these wires and connectors through the grommet hole into the passenger compartment.
8. From inside the glove box, remove the two screws that attach the fuse panel cover and the fuse panel itself to the left end of the glove box.
9. Disengage the harness from the two clips at the instrument cluster assembly and from the four clips along the lower edge of the instrument panel.
10. Starting at the right side forward end of the engine compartment, disconnect the harness connectors to the right headlight, parking light

and side marker light.
11. Disconnect the three harness wires at the starter relay assembly, and disengage the three wire loom from the retaining strap. Note the wire color codes and relay terminals for proper installation.
12. Disconnect the harness multiple connector to the regulator.
13. Working from front to rear, remove the harness from the retaining straps along the right fender apron.
14. Disengage the harness grommet from the hole at the right side of the dash, and pull the harness through the grommet hole into the passenger compartment.
15. The harness can now be removed from the vehicle.

Installation

1. From inside the vehicle, push the left section of the harness through the grommet hole at the left side of the dash panel as far as the grommet, and then engage the grommet to the dash. The left section of the harness is the section where a loom with two multiple connectors and one bullet connector comes out of the harness just forward of the grommet.
2. Engage the harness to the two clips at the instrument cluster assembly and the four clips along the lower edge of the instrument panel.
3. Push the right section of the harness through the grommet hole at the right side of the dash panel as far as the grommet, and then engage the grommet to the dash.
4. Push the center loom (with connectors) through the grommet hole at the center of the dash as far as the grommet, and then engage the grommet to the dash.
5. Position the fuse panel to the outer left side of the glove box, and the panel cover to the inner side. Then secure both panel and cover to the glove box with two retaining screws.
6. Make the harness connections to the dimmer switch, stop light switch, radio, heater and map light.
7. Working in the engine compartment, route the left and right sections of the harness along the left and right fender aprons respectively, and secure them in place with the retaining straps. Connect all the harness connectors to the same points from which they were disconnected during the removal procedure. Connect the multiple connector and bullet connector from the loom at the center grommet.

ECONOLINE

Removal

1. Disconnect the battery ground cable.
2. Working up from underneath the left corner of the instrument panel, disconnect the five connectors joining the instrument panel wiring harness to the dash-to-headlight junction wiring harness and to the rear wiring harness. Disengage the wiring harness locator from the tab at the side panel adjacent to the connectors.
3. Disconnect the dimmer switch connector. Remove the two dimmer switch wire locators from the dash panel.
4. At the brake pedal support, disconnect the stop light switch connector, the hazard flasher unit connnector, and the ground wire. Disengage the harness locator from the support.
5. Remove the screws retaining the instrument cluster assembly to the instrument panel. Pull the cluster rearward and allow it to rest against the steering column. Disconnect the cluster wiring loom multiple connector.
6. Disconnect the six-wire multiple connector to the steering column wiring. If the vehicle has a manual transmission, disconnect the back-up light switch connector under the steering column support, and pull the wires through the clip on the lower edge of the instrument panel.
7. Open the two clips at the upper edge of the instrument cluster opening in the panel by turning out the screws normally concealed by the top rim of the cluster. Disengage the harness from the clips. If the vehicle has an automatic transmission, disconnect the back-up light connectors above the upper right corner of the cluster opening.
8. Remove the ignition switch (Part 33-71). If the harness is to be replaced, remove the multiple connector from the switch.
9. Remove the brake warning light socket from the panel. Disconnect the connector at the horn relay. Disconnect the multiple connectors at the headlight switch and the windshield wiper switch.
10. Disconnect the connectors at the cigar lighter and its light. Disconnect the heater wiring multiple connector.
11. Remove the fuse panel from the engine housing side panel. Remove the glove compartment for access, and remove the harness locators from the side panel and the right side of the dash panel.
12. If the vehicle is equipped with an automatic transmission and/or auxiliary heater, remove the five straps holding the harness to the back-up light and/or heater thermostat wires.
13. Disconnect the three multiple connectors from the wiring harnesses to the engine and right headlight at the upper right corner of the dash panel. Disconnect the heater terminal connector at the end of the harness, and remove the instrument panel-to-dash wiring harness from the vehicle.

Installation

1. If a new harness is to be installed, transfer the fuses to the new fuse panel and transfer the brake warning light bulb to the new socket.
2. Set the wiring harness in place, along the right side of the dash panel through the glove compartment opening. Attach the three harness locators to the dash panel ahead of the glove compartment. Install the three straps holding the harness together with the back-up light wires and/or auxiliary heater wires, if so equipped.
3. Connect the three multiple connectors at the right of the harness. Connect the right end of the harness to the heater terminals. Install the glove compartment.
4. Install the fuse panel to the engine housing side panel. Install the harness locator to the side panel and install the two remaining straps holding the back-up light and/or heater wires to the harness, if so equipped.
5. If the vehicle has an automatic transmission, connect the two connectors to the back-up light switch wires which are strapped to the right portion of the harness. Connect the connector to the heater switch wiring.
6. Engage the harness to the two clips at the top of the instrument cluster opening in the instrument panel. Connect the connectors to the cigar lighter and its light, if so equipped.
7. Connect the multiple connector to the ignition switch, if disconnected, and install the switch. Connect the multiple connectors to the windshield wiper switch and the headlight switch. Install the brake

indicator light socket and connect the connector to the horn relay. Connect the courtesy light and accessory feed plugs which emerge from the harness at the same point as the wiper wires.

8. Connect the multiple connector to the steering column wiring. If the vehicle has a manual transmission, engage the back-up light wires in the clip at the bottom of the panel and connect the connector to the back-up light switch.
9. Connect the ground wire and the stop light switch and hazard flasher connections at the brake pedal support.
10. Connect the multiple connector to the instrument cluster wiring loom. Move the instrument cluster into position and secure it with the cluster retaining screws. **Do not kink the speedometer cable.**
11. Route the dimmer switch wires down the dash panel, install the two locators and connect the connector to the dimmer switch. Fit the floor mat over the switch.
12. Press the harness locator into position in the tab in the side panel adjacent to the upper left corner of the instrument panel. Connect the five wiring connectors at the end of the harness. **Observe the color coding to insure correct installation.**
13. Connect the battery ground cable and check the operation of the instrument panel gauges, lights and controls.

F-100-350 TRUCKS

The 14401 wiring harness starts at the front of the left fender apron where it plugs into another harness that goes to the left headlight. From this point, it runs back through a grommet in the left side of the dash panel into the passenger compartment. From the left grommet, the harness continues across the instrument panel to a similar grommet at the right of center of the dash panel where it returns to the engine compartment and terminates in several connections on the right fender apron.

Removal

1. Disconnect the battery ground cable.
2. Starting at the front of the left fender apron disconnect the harness plug from the left headlight wiring harness.
3. Disconnect the harness plug from the windshield washer motor and remove the loom from the motor and reservoir assembly (clip and screw).
4. Disconnect the harness multiple plug from the 14405 harness at the engine side of the dash panel.
5. Disengage the harness grommet from the hole at the left side of the dash, and push the grommet through the hole so that the left section of the harness can later be pulled into the passenger compartment.
6. Starting at the front of the right fender apron, disconnect the three harness multiple plugs from their connectors (to the relay assembly, to the right headlight wiring harness, and to the engine and regulator wiring harness).
7. Disconnect the harness wires from the starting motor relay. Note the color code and terminals for correct installation.
8. Pull the harness locator from the hole in the right fender apron, and disengage the harness from the straps and clips. Disconnect the harness from the engine harness at the rear of the engine. Disengage the harness grommet from the hole in the right center side of the dash panel and push the grommet through the hole so that the right section of the harness can later be pulled into the passenger compartment.
9. Remove the instrument cluster (Part 33-51) and the glove compartment liner.
10. Disconnect the harness wiring from the right door jam (courtesy light) switch and pull the wire up through the hole in the right cowl panel.
11. Pull the right section of the harness (that was disconnected at the right fender apron in steps 6 through 8) through the grommet hole at the right center side of the dash.
12. Remove the wiring harness from the hook-shaped clip under the right side of the instrument panel pad (not used on cowl-chassis models). Open the harness retainer along center of the dash panel, and remove the harness from the retainer (Fig. 1).
13. Disconnect the harness connectors at the hazard flasher and, the stop light switch connector.
14. Disconnect the dimmer switch connector.
15. Remove the screws retaining the fuse panel to the dash panel.
16. Disconnect the harness connectors to the steering column wiring, ignition switch, headlight switch, windshield wiper switch and cigar lighter and ash tray light, if installed. Remove the wiper switch illumination bulb from the rear side of the instrument panel (Fig. 2). Remove the screw retaining the grounded black wire terminal to the body structure. Disengage the harness from the retaining clips. (Fig. 2)
17. Disconnect the harness from the turn signal flasher, fuel sender wire(s), dome lightwire and the heater control assembly.
18. Disconnect the harness wiring from the left door jam (courtesy light) switch, and pull the wire up through the hole in the left cowl panel.
19. Pull the left section of the harness from the engine compartment through the grommet hole at the left side of the dash into the passenger compartment. Remove the harness from the vehicle.

Installation

1. If installing a new wiring harness, transfer fuses, clips and wiper switch illumination bulb components to the new assembly as required.
2. Position the harness under the instrument panel. Push the right section of the harness (the end with three multiple connectors and three push-on connectors) through the grommet hole (at the right center side of the dash panel) into the engine compartment as far as the grommet. Engage the grommet in the hole.
3. Route the other right branch of the harness through the opening in the right cowl panel and connect it to the right door jam (courtesy light) switch.
4. Install the wiring harness in the retainers at the right side of the instrument panel. On all except cowl-chassis models, engage the wiring assembly in the hook-shaped clip at the extreme right of the panel. On cowl-chassis models, attach the harness clips to the upper lip of the instrument panel with two bolts and nuts and torque to 25-35 in-lbs.
5. Install the glove compartment liner.
6. Continuing from right to left, install the remainder of the wiring harness clips. On all except cowl-chassis models, engage the wiring harness in the clips on the steering column support.
7. Push the left section of the harness (with connectors) through the hole at the left side of the dash panel and into the engine compartment as far as the grommet. Engage the grommet in the hole.
8. Connect the harness connectors to the steering column wiring, ignition switch, headlight switch, windshield wiper switch, cigar lighter and ash tray light as applicable. Install the wiper switch illumination light to the instrument panel. Install the

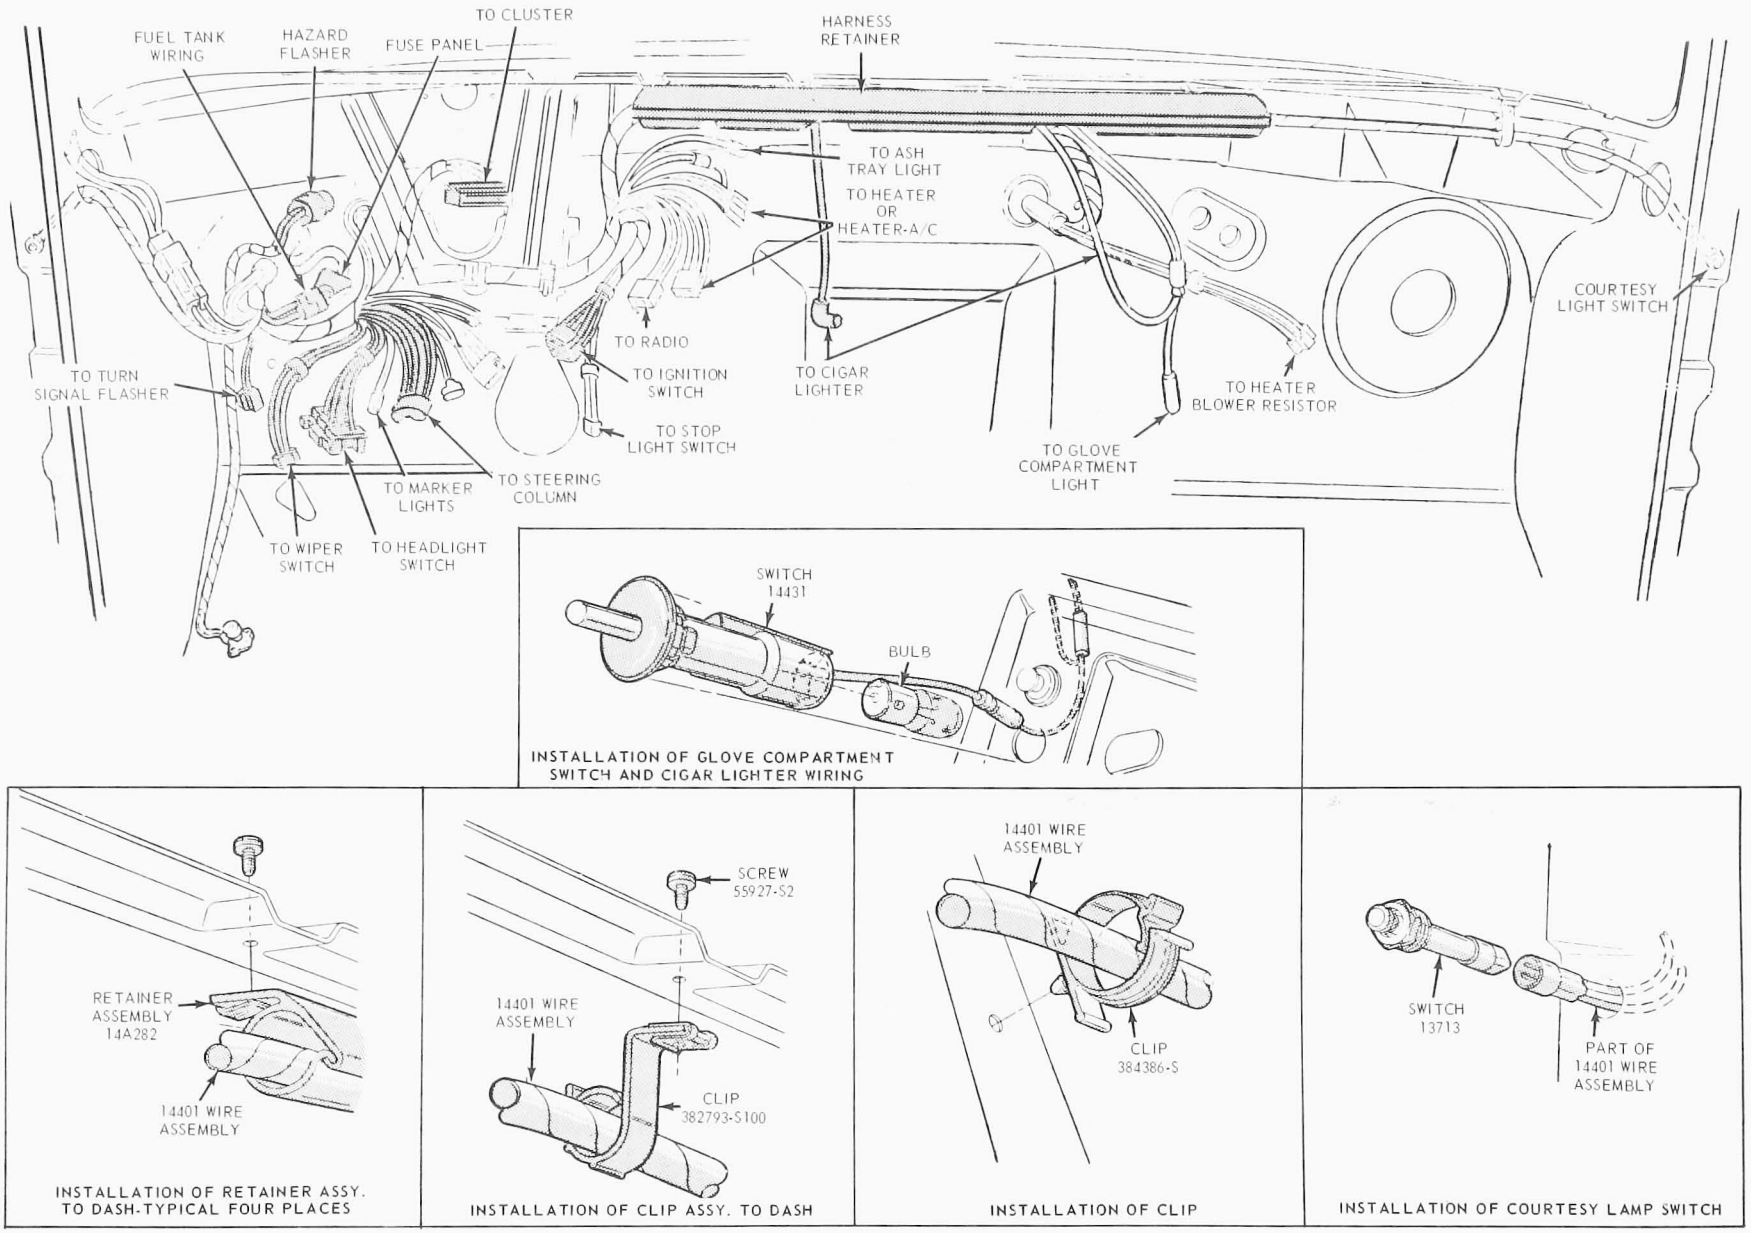

FIG. 1 F-100 through F-350 Truck 14401 Harness Routing.

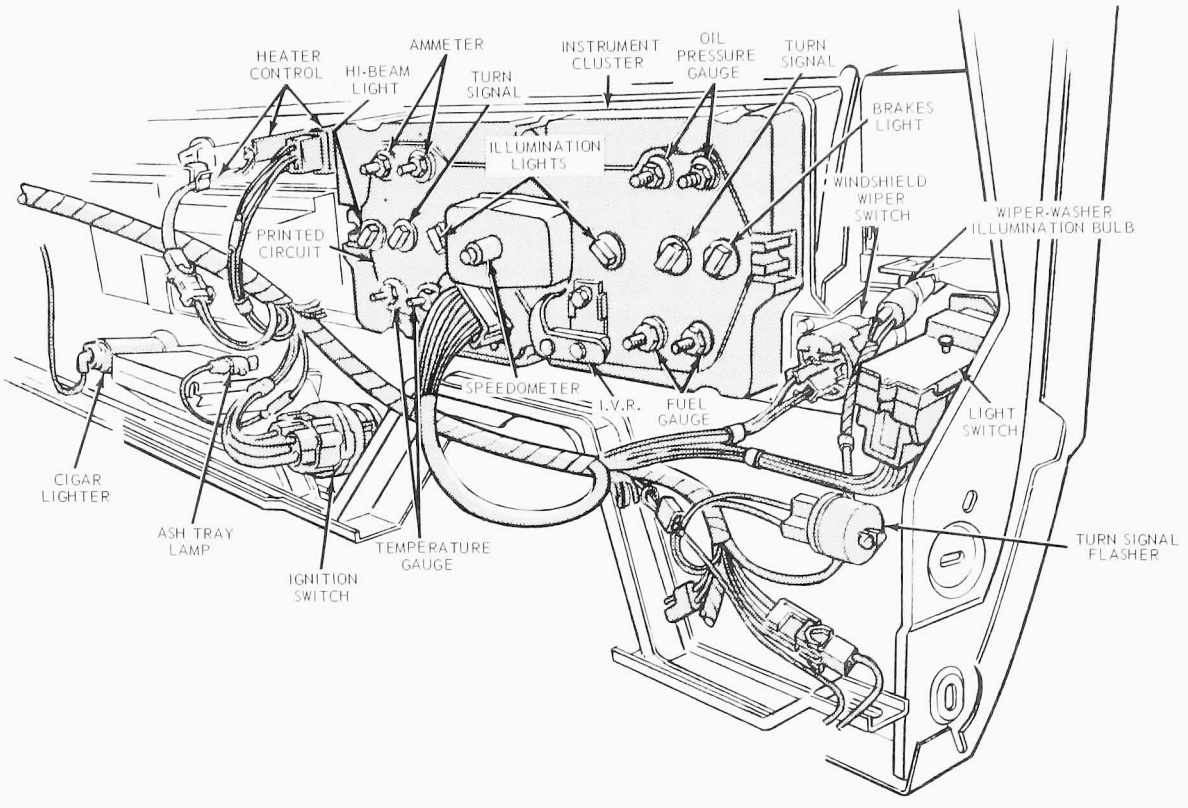

FIG. 2 F-100 Through F-350 Instrument Panel Wiring

black grounded wire terminal to the instrument panel structure with the screw.

9. Connect the harness to the turn signal flasher, fuel sender wire(s), dome light wire and the heater control assembly.
10. Install the fuse panel to the dash panel with two retaining screws.
11. Connect the harness connector to the dimmer switch.
12. Connect the harness connectors to the hazard flasher and, the stop light switch connector.
13. Route the left branch of the wiring harness through the opening in the left cowl panel, and connect it to the left door jam (courtesy light) switch.
14. Install the instrument cluster (Part 33-51).
15. Now working in the engine compartment, route the left section of the harness along the left fender apron, and connect the harness multiple plug to the 14405 harness near the dash panel.
16. Connect the harness plug to the windshield washer motor and route wiring under windshield washer reservoir. Install locators in holes in fender apron.
17. Connect the harness plug to the left headlight harness connector at the center of the left fender apron.
18. Connect the two harness looms coming out of the grommets at the left center area of the dash (multiple plug and bullet connectors).
19. Engage the locators of the harness right section in the holes in the right fender apron.
20. Connect the three harness wires to the starting motor relay terminals. Follow the color code and terminal connections as noted during the removal procedure.
21. At the center of the right fender apron, connect the three harness multiple plugs to their respective connectors (from the relay assembly, from the right headlight wiring harness, and from the engine and regulator wiring harness).
22. Connect the battery ground cable and check the operation of all switches, gauges and other electrical equipment connected to the dash panel-to-instrument panel wiring harness.

F-AND B-500-750 SERIES TRUCKS

Removal

1. Disconnect the battery ground cable.
2. Disconnect the socket from the right headlight. Then, remove the ground wire screw from the right side of the radiator support.
3. Disconnect the horn wire and right turn signal light from the harness at the radiator support. Then, disengage the wire locator and pull the harness into the engine compartment through the opening in the radiator support.
4. Disconnect the multiple connector from the charging system harness and the harness wires from the starter solenoid. Then, remove the harness from the strap clamps and push the dash panel grommet into the cab from the engine compartment.
5. Disconnect the harness from the left headlight and the left turn signal light. Remove the ground wire screw from the radiator support.
6. Disconnect the harness from the junction block on the left fender splash shield.
7. Disconnect the connectors at the left side of the dash panel. Then, push the grommet from the dash panel into the cab.
8. Disconnect the harness connectors at the center of the dash panel behind the engine. Push the harness grommet out of the dash panel into the cab.
9. Working inside the cab, disconnect the harness wires from the right door jamb switch, if so equipped.

10. Remove the glove box liner and instrument cluster from the instrument panel.
11. On Conventional truck models, remove the screws retaining the fuse panel to the side cowl panel. Disconnect the wiring harness from the right door jam (courtesy light) switch and pull the wire up through the grommet in the right cowl panel.

On cowl-chassis trucks and buses, remove the nut from the junction block post on the right cowl side panel and disconnect the single-wire connectors for both black wires of the harness. Also disconnect the two black-white stripe wires from the terminal posts on the adjacent circuit breaker.

12. Remove the screws or stud nuts retaining the harness clips to the instrument panel and work the harness toward the left side of the cab. On conventional truck models, two clips must be removed from the steering column support.
13. Disconnect the connectors to all instrument panel switches connected to the wiring harness. Remove the dual brake indicator light assembly from the instrument panel.
14. Disconnect the turn signal switch connector at the bottom of the steering wheel hub. Carefully remove the two steering column clips that retain the switch wires and (on conventional trucks only) disengage the wires from the clips on the left side of the steering column support bracket.
15. Disconnect the wires from the transistorized flasher unit. Disconnect the black ground wire terminal retained to the instrument panel structure by a screw.
16. Disconnect the headlight dimmer switch wiring connector (it may be necessary to remove the switch first), and (on cowl-chassis trucks and buses only) disconnect the black wire from the junction block post at the left cowl side panel.
17. Disconnect all connectors of the harness at the upper left corner of the dash panel. Disconnect the harness wiring from the left door jam (courtesy light) switch, and pull the wire up through the grommet in the left cowl panel. Remove the wiring harness.

Installation

1. If installing a new wiring harness, transfer fuses, clips and dual brake indicator light components to the new harness as required.
2. Position the wiring harness under the instrument panel.
3. Route the engine compartment ends of the harness through the openings in the dash panel, and seat the grommet in the hole at each location.

On conventional model trucks, install the fuse panel to the right cowl side panel and connect the multiple connector to the relay. Route the right end of the harness through the opening in the right cowl panel and connect it to the right door jam (courtesy light) switch. Position the grommet in the opening.

On cowl-chassis trucks and buses, install the two single black wires to the post of the separate junction block on the cowl side panel. Install the two black-white stripe wires to the terminal posts on the adjacent circuit breaker, with the shorter wire going to the top post.

4. Install the screws or stud nuts retaining the wiring harness clips to the right and center areas of the instrument panel. On conventional trucks, also install two retaining clips on the steering column support.
5. Install the glove compartment.
6. Connect the connector to the stop light switch wiring.
7. Connect the harness connectors to all instrument panel electrical switches. Install the dual brake indicator light.
8. Plug the turn signal switch wiring connector into the socket at the bottom of the steering columm hub. Route the wires along the top left of the steering column and install the two retaining clips to the column. On conventional trucks, engage the wires in the clips on the left side of the steering column support bracket and tighten the screws retaining the clips.
9. Connect the wires to the flasher unit terminals. Attach the terminal of the black ground wire to the instrument panel structure with the screw.
10. Connect the headlight dimmer switch wiring connector. On cowl-chassis trucks and buses, connect the black wire terminal to the junction block post at the left cowl side panel.
11. Connect all harness connectors at the upper left corner of the dash panel.

Route the left end of the wiring assembly (with grommet) through the opening in the left cowl panel, and connect it to the left door jam (courtesy light) switch. Position the grommet in the opening.

12. Install the instrument cluster and wiring assembly (Part 33-51).
13. Connect the harness connectors at the center of the dash panel behind the engine.
14. Route the harness along the left fender apron, and connect the connector to the left headlight. Connect the harness to the left turn signal and the ground wire to the radiator support.
15. Connect the harness to the junction block on the left fender splash shield. Connect the connectors at the left side of the dash panel.
16. Route the harness along the right fender apron and position the harness in the strap clamps. Push the harness locators into the locator holes.
17. Connect the harness to the horns, turn signal light and headlight bulb. Connect the ground wire to the radiator support with one screw.
18. Connect the harness wires to the starter solenoid and the harness connector to the charging system wire harness.
19. Connect the battery ground cable and check the operation of all switches, gauges and other electrical equipment connected to the 14401 wiring harness.

L-SERIES TRUCKS

The rear terminals of this harness start at a junction block which is mounted on the right inner side of the cab rear panel behind the passenger seat. From the junction block, the harness is routed forward under the right door sill.

On city delivery models, the harness continues from under the right door sill up to the right side of the dash panel where the fuse panel (which is part of the harness assembly) is mounted.

On Line Haul models, the harness is routed from under the door sill up along the right door front pillar to the fuse panel at the right side of the instrument panel.

On all models, the harness continues from the fuse panel to the left behind the instrument panel, where its branch wires connect to the various instruments and controls, and then it comes out into the engine compartment through an opening at the upper left side of the dash panel. The forward terminals of the harness connect to the junction block that is mounted to the upper engine side of the dash panel.

1. Disconnect the battery ground cable. Remove the cover from the junction block at the cab rear panel. Remove the retaining nuts and disconnect the harness wires from the junction block terminal posts. The color codes of the wires relative to the terminal posts should be

carefully noted for correct installation.

2. Remove the harness retaining clip from the floor pan in back of the door opening (1 screw) and the cover from the side of the right door sill.
3. **On City Delivery models,** remove the harness cover from the floor pan forward of the door opening (2 retaining screws). Remove the clips that retain the harness to the inner side of the dash panel. At the fuse panel, disconnect the wires coming from another wiring harness, and remove the fuse panel from the dash panel (2 retaining screws).

On Line Haul models, remove the metal retainer that carries the harness up along the right door front pillar (3 retaining screws). Remove the fuse panel cover from the right side of the instrument panel, remove the retaining nuts, and disconnect the harness wires from the fuse panel terminal posts. The color codes of the wires relative to the terminal posts should be carefully noted for correct installation.

4. Remove the retaining screws and swing the instrument cluster sections away from the instrument panel for access. Disconnect the harness connectors to the turn signal/hazard flasher switch, the cigar lighter, the light switch, the ignition switch, the dimmer switch and the roof marker lights.
5. Disconnect all other harness connections to the instrument cluster and panel. These connections will vary with the individual vehicle according to model and equipment used. Carefully note these connections for correct installation.
6. Open the cover of the junction box on the engine side of the dash panel. Remove the retaining nuts and disconnect the harness wires from the junction block terminal posts. The color codes of the wires relative to the terminal posts (Figs. 3, 4 and 5) should be carefully noted for correct installation.
7. Disengage the harness from the retaining clips on the engine side of the dash panel and pull the forward end of the harness back through the dash panel opening into the drivers compartment. Work the harness to the right behind the instrument panel and out of the vehicle.
8. If the harness is being replaced, transfer all retaining clips to the new assembly. On City Delivery models, also transfer the fuses to the new fuse panel which is part of the harness assembly.
9. Work the forward end of the new harness in behind the instrument panel from right to left and then up through the opening at the upper left side of the dash panel. Work the rearward end of the harness under the right door sill and back to the junction block at the cab rear panel.
10. Make all the harness wiring connections according to the correct color code-to-terminal and connector relationship as noted during removal. Attach all the retaining clips to their proper location.

C-SERIES TRUCKS

Removal

1. Remove the battery cover and disconnect the battery ground cable(s).
2. Disconnect the two connectors to the right front turn signal light and remove the wiring harness from the two clips at the right side of the dash panel.
3. Disconnect the multiple connector to the relay wiring and the two single connectors to the buzzer mounted at the center of the dash panel. Disconnect the red and red-black stripe wire connectors to the stop light switch above the relay and buzzer on tractor units. Disconnect the multiple connectors of the branch leading down to the under-cab wiring assembly which extends upward from the center of the floor. Lift the wiring harness from the two clips at the center of the dash panel.
4. Disconnect the speedometer and tachometer cables at the instrument cluster. Remove the screws retaining the cluster to the instrument cluster housing, and tilt the cluster rearward enough to gain access to the wiring.
5. Disconnect the three multiple connectors to the instrument cluster wiring assembly. Disconnect the wires for the tachometer light, air gauge or vacuum gauge light, and cigar lighter light from the connector at the two blue-red stripe wires of the wiring harness.
6. Remove the nut from the terminal block post on the dash panel above the fuse panel. Remove the three wire terminals from the post, disengage the long black wire from the clip and remove the wire from the ammeter loops at the back left of the instrument cluster.
7. Disconnect the harness connectors at the ignition switch, marker light switch, headlight switch and cigar lighter. Disconnect the black wire connector to the roof marker lights. Adjacent to the ignition switch connector, also disconnect the red-blue stripe wire from one two-wire connector and disconnect the red-yellow stripe wire and the red-green stripe wire from the other two-wire connector, if so equipped. Disconnect the connector for the two orange wires from the fuel tank sending unit wire.
8. Disconnect the brown wire from the heater switch. Disconnect the connector to the back-up light switch wiring. Disconnect the connectors to the stop light switch. Disconnect the connector to the air pressure switch, if so equipped.
9. Disconnect the turn signal switch multiple connector at the top of the steering column hub or below the separate turn signal switch mounted at the side of the column. Remove the two clips from the steering column and disengage the wiring assembly branch from the clip under the steering column support bracket at the base of the instrument panel.
10. Disconnect the connector at the headlight dimmer switch and disengage the harness branch from the two clips on the dash panel.
11. Disconnect the wires to the two-speed axle circuit breaker at the upper right corner of the fuse panel. Remove the three screws retaining the fuse panel to the dash panel, and remove the fuse panel.
12. Disconnect the harness multiple connectors at the upper left corner of the cab floor. Disconnect the headlight wiring connector above the floor. If equipped with a fuel shut-off circuit breaker on the cowl side panel, disconnect the wires to the circuit breaker terminal posts. Remove the screws retaining the two harness clips to the cowl side panel. Disconnect the harness connectors at the transistorized flasher unit on the cowl side panel and disconnect the black-blue stripe wire connector to the dome light wire. Disconnect the connectors to the left front turn signal light wiring.

Installation

1. If installing a new wiring harness, transfer fuses, clips, etc. to the new assembly, as required.
2. Install the fuse panel to the dash panel with the three retaining screws. Connect the wiring harness multiple connectors at the upper left corner of the cab floor, including the

FIG. 5 Dash Panel Junction Blocks—L-Series with Diesel Engine

connector to the headlight wiring assembly.

3. Work the wiring harness into position under the instrument panel, engaging it in the one hook-shaped clip on the left side of the dash panel and the four hook-shaped clips at the center and right side of the dash panel. Connect the two connectors to the right front turn signal light wiring.
4. Connect the green-yellow stripe wire of the two-speed axle circuit to the top terminal post of the circuit breaker in the top right corner of the fuse panel. Connect the green wire to the bottom terminal post of the circuit breaker.
5. Engage the dash panel-to-instrument panel wiring harness, together with the other wiring harnesses which are routed along the left cowl side panel, in the two clips. Attach the two clips to the left cowl side panel with the clip retaining screws. Connect the red-white stripe wire to the terminal nearest the top corner of the flasher unit on the cowl side panel. Connect the blue wire to the remaining terminal of the flasher unit. Connect the adjacent black-blue stripe wire to the dome light feed wire. If equipped with a fuel shut-off circuit breaker mounted adjacent to the lower wiring assembly clip on the cowl side panel, connect the terminal for the red-green stripe wire and the orange-blue stripe wire to the forward terminal post of the circuit breaker. Connect the green-red stripe wire to the rear terminal post.
6. Connect the connectors for the left front turn signal light wiring. Connect the connector and the terminal for the two black-green stripe wires to the ignition switch. At the harness branch leading to the ignition switch, connect the connector of the two red-blue stripe wires to the separate red-blue stripe wire. To the other two-wire connector, connect the red-yellow stripe wire and the red-green stripe wire, if so equipped. Attach the orange-green stripe wire terminal to the air pressure switch on the air manifold with the screw and washer, if so equipped.
7. Connect the two black wires to the marker light switch terminals, and connect the remaining black wire to the roof marker light wire. Connect the connector for the two orange wires that branch out from the wiring harness trunk at the same point as the marker switch wires connect to the orange wire of the fuel tank sending unit circuit. Connect the adjacent red-brown stripe wire to the two-wire connector for the red and red-brown stripe wires of the wiring assembly from the primer switch.
8. Connect the multiple connector to the headlight switch. Connect the red wire from the same branch to the rear terminal of the adjacent stop light switch, and connect the red-black stripe wire to the forward terminal of the switch, if so equipped.
9. Connect the push-on connector of the blue-white stripe wire to the cigar lighter terminal. Connect the bulb leads from the cigar lighter, tachometer, and air pressure or vacuum gauge to the connector of the two blue-red stripe wires coming out of the harness.
10. Connect the three multiple connectors to the instrument cluster wiring assembly. Route the black wire from the same branch through the ammeter loops from left to right and then to the junction block on the left side of the dash panel. Place the lock washer on the post of the junction block, followed by the terminal for the short length of black-yellow stripe wire and the terminal for the short lengths of black and black-orange stripe wires extending from the adjacent harness trunk. Then place the ammeter wire terminal on the post and install the retaining nut.
11. Connect the connector to the headlight dimmer switch. Install the dimmer switch branch wires in the two clips at the dash panel.
12. Connect the multiple connector to the turn signal switch. Engage the harness branch in the clip under the steering column support bracket at the base of the instrument panel. Install the two clips to retain the wires along the left side of the steering column.
13. Connect the brown wire connector to the heater switch. Connect the two-wire connector to the back-up light switch wiring.
14. Attach the three harness clips to the dash panel with the screws and flat washers. Retain the pink resistance wire within the loop of the left clip which is installed directly ahead of the installed position of the air pressure or vacuum gauge in the instrument cluster.
15. Position the instrument cluster in the housing and install the screws retaining the cluster to the housing. Connect the speedometer and tachometer cables.
16. Connect the multiple connectors of the harness branch for the under-cab wiring assembly which extends from the front center of the floor. Connect the connector to the three relay wires at the center of the dash panel. At the buzzer just to the left of the relay, connect the orange-green stripe wire to the left terminal and connect the orange-blue stripe wire to the right terminal. On tractor units, connect the red wire to the forward terminal of the stop light switch at the air manifold adapter above and to the right of the relay. Connect the red-black stripe wire to the rear terminal of the switch.
17. Connect the battery ground cable(s) and install the battery cover. Check the operation of all switches, lights, gauges and other electrical equipment connected to the dash panel-to-instrument panel wiring harness.

PART 34-11 Left Side Dash Panel to Headlight Junction Wiring Harness

COMPONENT INDEX Applies to Models as Indicated	MODEL APPLICATION Econoline	L-Series	C-Series
REMOVAL AND INSTALLATION	11-01	11-01	11-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.

REMOVAL AND INSTALLATION

ECONOLINE

Removal

1. Disconnect the battery ground cable.
2. Raise the vehicle and disconnect the brake warning switch shell cap connector at the pressure differential valve mounted on the rear of the underbody crossmember. Work the wire grommet out of the hole in the crossmember, pry the four plastic wiring assembly locators out of the holes in the underbody flanges, and pull the brake warning circuit wires free from the underbody. Two of the locators are in the bottom flange of the lengthwise member, and two are in the top flange of the forward crossmember.
3. Lower the vehicle, raise the hood, and disconnect the connector to the windshield washer pump motor. Disconnect the lead to the horn(s) and the multiple connectors to the left headlight, parking light and side marker light.
4. Disconnect the harness locators from the dash panel, and pull the lower end of the wiring harness up and out of the underhood area.
5. Disconnect the ground wire from the left side panel. Disconnect the harness locators at the top of the dash panel, and disengage the harness from the clips on the dash panel.
6. Working up from underneath the left side of the instrument panel, disconnect the multiple connector. Work the harness grommet out of the hole in the dash panel and guide the harness forward out of the hole.
7. Remove the wiring harness from the underhood area of the vehicle.

Installation

1. Support the wiring harness over the top of the underhood area and feed the end of the harness into the hole in the upper left of the dash panel.
2. Connect the multiple connector under the instrument panel. **To avoid improper connections, be sure that the two blue colored connectors are mated.** Engage the harness grommet in the hole in the dash panel.
3. Route the harness down the dash panel into position. Attach the harness locators to the dash panel and engage the harness in the clips.
4. Install the ground wire to the left side panel. Connect the wiper motor multiple connector.
5. Connect the multiple connectors to the left headlight, parking light and side marker light wires. Connect the lead to the horn(s). Connect the connector to the windshield washer pump motor.
6. Raise the vehicle. Install the harness locators to the top flange of the forward underbody crossmember and the lower flange of the lengthwise member.
7. Route the end of the harness (brake indicator light circuit) rearward through the hole in the crossmember and connect the shell cap connector to the brake indicator switch on the pressure differential valve. Install the grommet in the hole in the crossmember.
8. Lower the vehicle and connect the battery ground cable. Check the operation of all components supplied by the wiring harness.

L-SERIES TRUCKS

This wiring harness connects a junction block at the upper center of the dash panel to a junction block at the front end left side of the hood. The wiring harness is strapped to a support rod that runs from the center of the dash panel to the center of the radiator.

To remove the harness, raise the hood, disconnect the battery ground cable, and open the junction block cover at the dash panel. Remove the retaining nuts and disconnect the harness wires from the junction block terminal posts. The color codes of the wires relative to the terminal posts (Figs. 1, 2 and 3) should be carefully noted for correct installation.

Remove the two harness mounting clips at the dash panel, the four retaining straps along the support rod and the four retaining clips along the radiator left support.

The harness continues from the radiator left support through a shield which is mounted to a bracket on the left side of the front crossmember. Remove the shield from the bracket (two retaining screw and washer assemblies and two nuts). Bend the shield retaining tabs out, and separate the wiring harness from the shield.

Remove the retaining nuts and disconnect the harness wires from the terminal posts on the junction block at the front end left side of the hood. The color codes of the wires relative to the terminal posts should be carefully noted for correct installation.

Remove the four harness retaining clips from the left front of the hood

assembly, pull the harness back through the opening in the hood left brace and remove the assembly from the vehicle.

When replacing the harness, transfer all the retaining clips and straps to the new assembly. Before mounting the wiring shield to the bracket on the front crossmember, assemble the harness to the shield and secure the harness in the shield by bending in the retaining tabs. Be sure to make all junction block connections according to the color code-to-terminal relationship as noted during removal.

C-SERIES TRUCKS

The dash panel-to-headlight junction wiring harness is retained by clips to a transverse structural member of the cab front end, slightly below the level of the headlights. From the left light wiring connectors, the harness is routed up through a grommet in the toe board area of the dash panel just forward of the headlight dimmer switch. It terminates in a two-wire connector to the instrument panel wiring harness a short distance beyond the grommet. Access to the wiring harness can be gained by tilting the cab after disconnecting the connector in the driver's compartment.

FIG. 3 Dash Panel Junction Blocks L-Series With Diesel Engine

PART 34-12 Right Side Dash Panel to Headlight Junction Wiring Harness

REMOVAL AND INSTALLATION

ECONOLINE

1. At the upper right side of the dash panel disconnect the two multiple connectors and the one bullet connector if so equipped.
2. Disconnect the multiple connectors to the right headlight, parking light and side marker light.
3. Disengage the harness from the two straps on the right side panel and from three clips on the dash panel. Remove the harness from the vehicle.
4. Install the new harness (end with 3 connectors down, end with 1 connector up) to the side panel and dash panel and secure it in place with the four retaining clips.
5. Connect the multiple connectors to the right headlight, parking light and side marker light.
6. Connect the opposite end of the harness to the two multiple connectors (and one bullet connector if so equipped) at the upper right side of the dash panel.

PART 34-31 Fuses and Circuit Breakers

A page number indicates that the item is for the vehicle(s) listed at the head of the column.

GENERAL INFORMATION

FUSE PANELS

Each vehicle has a fuse panel which contains most of the fuses used in the electrical system. The fuse panels are located in various positions depending upon the vehicle as shown in Figs. 1 through 8 which show the fuse panels for each vehicle line.

The circuit protection charts in Specifications of this Part give the location and values of **all** the circuits containing fuses or circuit breakers for the various vehicle lines.

ELECTRICAL CONSOLE—W-SERIES

An electrical console (Fig. 6) is located to the right of the driver's seat. This console consists of a series of in-line toggle switches and a circuit protection panel, both of which are mounted on a hinged cover. Two types of circuit protection panels are available: one type contains both fuses and circuit breakers (Fig. 7); the other contains circuit breakers only (Fig. 8).

FUSE PANEL ATTACHED TO LEFT END OF GLOVE BOX

1. (20 AMP) HAZARD FLASHER SYSTEM
2. (15 AMP) DOME LIGHT AND CIGAR LIGHTER
3. (2 AMP) INSTRUMENT PANEL AND CLUSTER LIGHTS
4. (14 AMP) TURN SIGNALS, RADIO, BACK-UP LIGHTS, WINDSHIELD WIPER/WASHER
5. (20 AMP) HEATER

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

DESCRIPTION AND OPERATION

RADIO

The radio is optional and is available on all models to receiveAM radio programs. An AM-FM radio is also available on F-100 through F-350 model trucks. It is equipped with a combination ON—OFF switch and volume control, a tone control, and a manual tuning control. All models except the Bronco, C-and W-Series have the five station selecting push buttons. The push buttons, which are located below the radio dial, can be preset to any stations desired.

CHASSIS CONNECTORS

F-100 THROUGH F-350

The antenna lead-in receptacle is located on the back of the radio at the right lower corner (Fig. 1). The antenna trimmer is located just above the antenna receptacle. The power and speaker leads are located on the back side of the radio at the left corner.

A permanent magnet speaker is mounted to the instrument panel above the radio (Fig. 1). It is connected to the radio by two wires and a plug connector.

Do not operate the radio unless the speaker is connected to the radio. To do so may damage the power transistor.

F-AND B-500 THROUGH 750

The antenna connector receptacle is located on the bottom of the radio at the right rear corner. The antenna trimmer is located in a hole on the front of the radio below the tuning control (Fig. 2). The power A lead and speaker leads are located on the left side of the radio.

A permanent magnet speaker is mounted to the instrument panel above the radio (Fig. 2). It is connected to the radio by two wires and a plug connector.

Do not operate the radio unless the speaker is connected to the radio. To do so may damage the power transistor.

ALL MODELS EXCEPT F-SERIES

The antenna connector and the antenna trimmer are located on the right side of the radio. The A lead is attached to the left side of the unit.

A permanent magnet speaker is used with all radio applications. The speaker mounts in the instrument panel, except on the L-and W-Series. On L-and W-Series the speaker is mounted on the roof panel (Figs. 3 and 4) and are connected to the receiver by a plug connector.

Do not operate the radio without the speaker connected, as it may damage the power transistor.

ANTENNA TRIMMING

Each radio assembly has an antenna trimmer located in the body of the assembly. The purpose of the trimmer is to adjust the antenna circuit for variations of length, so that many types of antennas may be matched perfectly to the requirements of each radio assembly.

The antenna trimmer should be readjusted when a new antenna or lead-in cable is installed. To trim the antenna, proceed as follows:

1. Inspect the antenna lead-in plug and socket to be sure that they are clean. Clean them if required.
2. Extend the antenna to its maximum length and position the vehicle in an open area away from steel buildings.
3. Turn the radio on.
4. Tune the radio to a weak station around 1600 KC (16 on the dial). Adjust the volume control so that the station is barely audible.
5. Adjust the antenna trimmer to obtain maximum volume from the station.

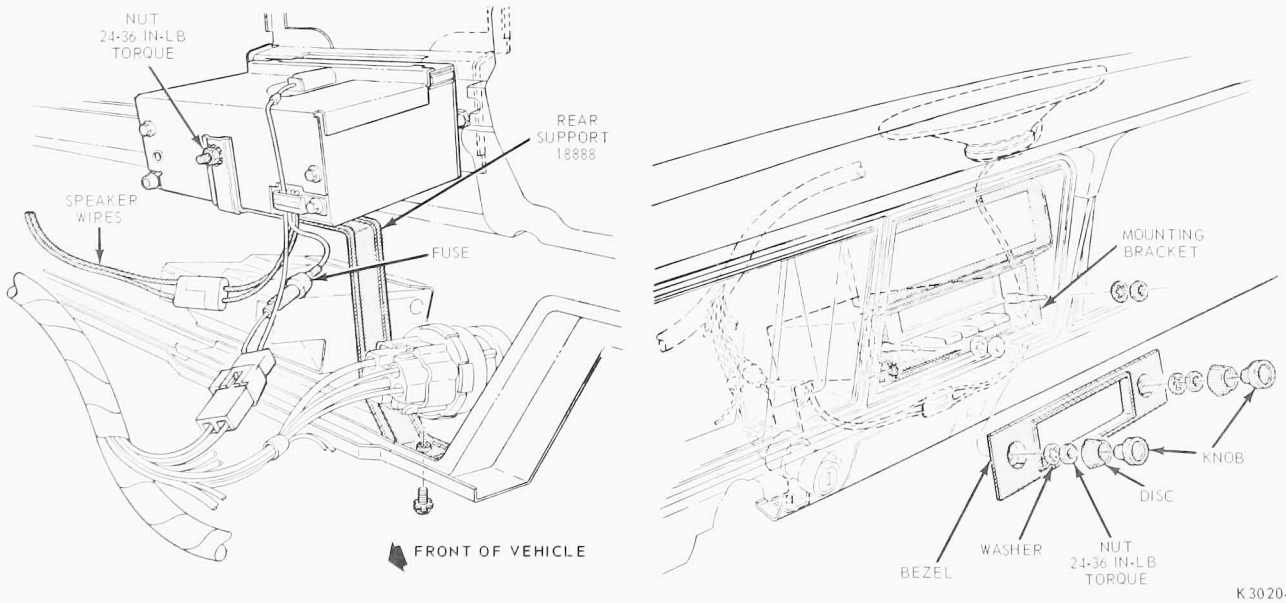

FIG. 1 Radio Installation—F-100 Through F-350

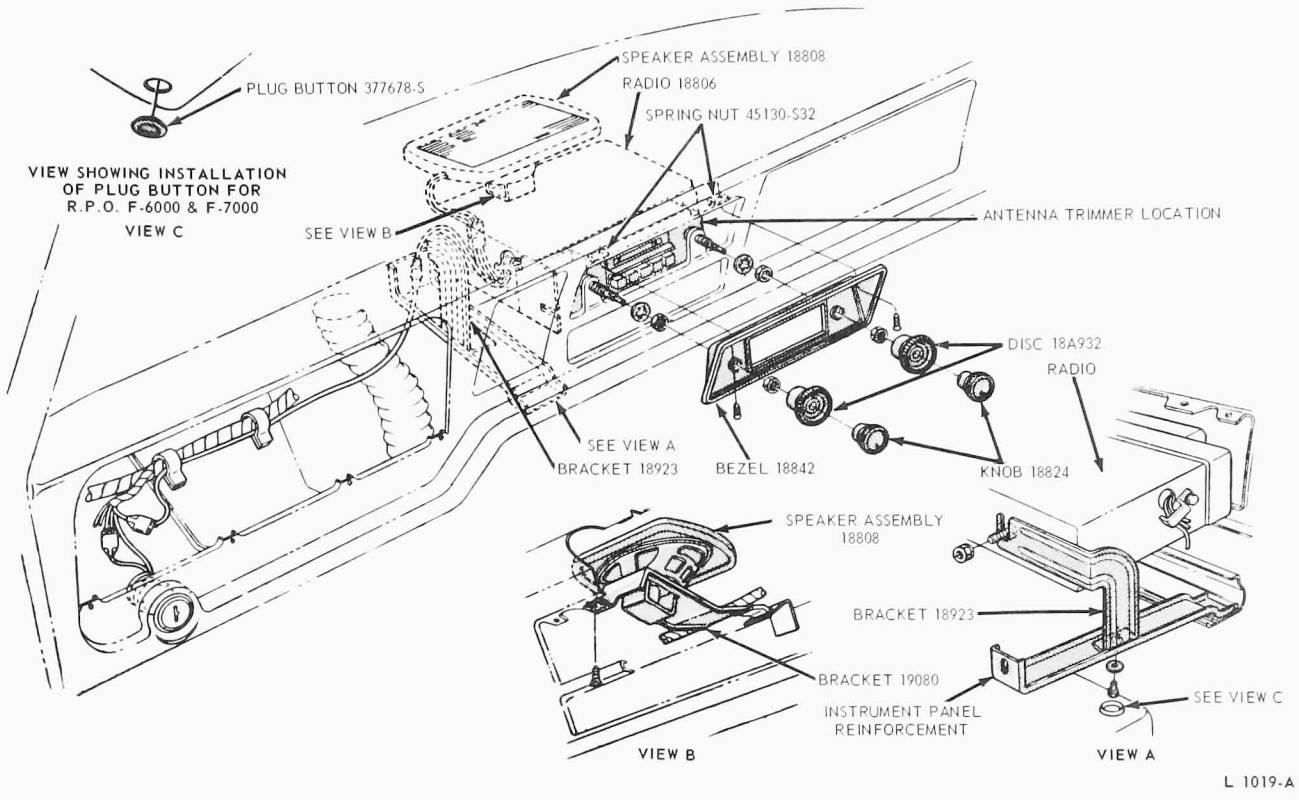

FIG. 2 Radio Installation—F-500-750

TESTING

RADIO

A radio tester, Tool T65P-18805-A, is designed for in vehicle usage to rapidly diagnose radio malfunctions and determine if the problem is in the radio, antenna, or the speaker. Testing instructions are located on the side of the tester housing.

The radio tester can save considerable time in servicing all models and makes of radios. Use of the tester eliminates the need for substituting known quality components.

ADJUSTMENTS

PUSH BUTTONS

Turn the radio on, and allow it to warm up for 15 minutes. Extend the antenna to a height of approximately 33 inches.

Pull out the push button to be set to unlock the push button mechanism. Tune in the desired station with the manual tuning knob. After the station is clearly tuned in, push the button straight in until it stops, then release it.

Repeat this procedure for the remaining buttons.

REMOVAL AND INSTALLATION

RADIO

F-100 THROUGH 350

Removal

1. Disconnect the battery ground cable.
2. Remove the ash tray and bracket.
3. Disconnect the antenna lead-in cable, speaker wires and radio feed (Power) wire.
4. Remove the bolt attaching the radio rear support to the lower edge of the instrument panel (Fig. 1).
5. If equipped with A/C, disconnect the left A/C duct hose from the A/C plenum.
6. Remove the knobs and discs from the radio control shafts.
7. Remove the bezel retaining nuts and washers from the radio control shafts, and remove the bezel.
8. Remove the nuts and washers from the radio control shafts, and remove the radio and bracket from the instrument panel.

Installation

1. Position the radio and bracket to the instrument panel, and install the nuts and washers on the radio control shafts.
2. Position the radio rear support to the lower edge of the instrument panel, and install the attaching bolt.
3. Connect the antenna lead-in cable, speaker wires and feed (Power) wires to the radio.
4. Position the bezel to the radio opening, and install the washers and nuts on the radio control shafts. Install the knobs and discs on the radio control shafts.
5. Check the radio operation and

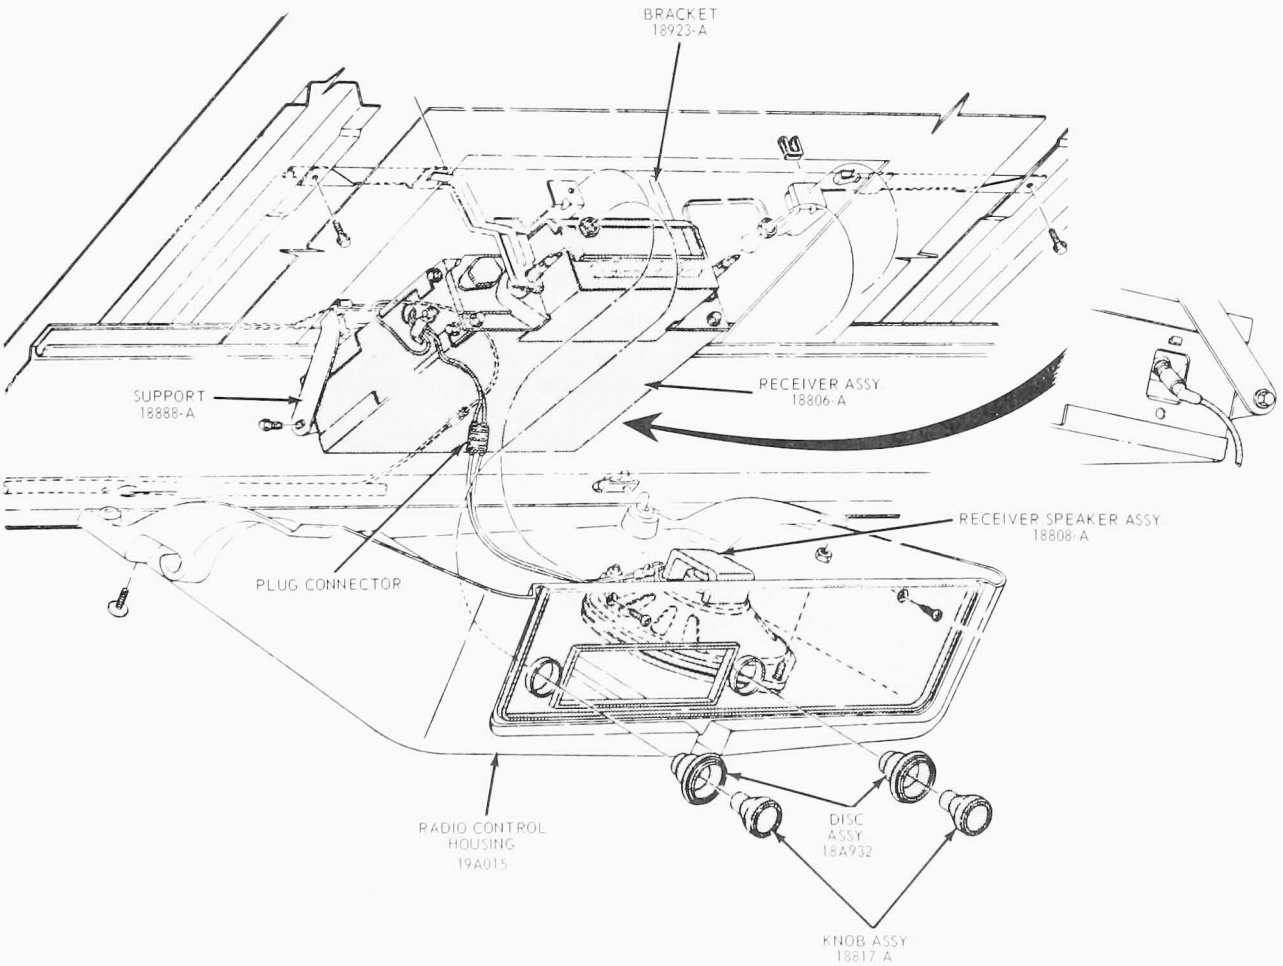

FIG. 3 Radio Installation—L-Series

adjust the antenna trimmer.
6. Connect the left A/C duct hose to the A/C plenum, if equipped with A/C.
7. Install the ash tray bracket and ash tray.

F-AND B-500 THROUGH 750

Removal

1. Disconnect the battery ground cable.
2. Disconnect the radio power lead, antenna lead-in cable and the speaker lead wires at the radio (Fig. 2).
3. Pull off the two control knobs and discs from the radio control shafts.
4. Remove the two bezel retaining nuts from the radio control shafts and two bezel attaching screws, and remove the bezel.
5. Remove the support bracket from the back of the radio.
6. Remove the two radio retaining nuts from the radio control shafts and remove the radio.

Installation

1. Position the radio to the instrument panel and install the two retaining nuts on the radio control shafts.
2. Install the support bracket on the back of the radio.
3. Tighten the retaining nuts on the radio control shafts.
4. Position the bezel to the radio and install the two bezel retaining nuts. Install the two bezel attaching screws.
5. Install the disc knobs and control knobs on the radio control shafts.
6. Connect the radio power lead, radio speaker wires and the antenna lead-in cable to the radio.
7. Connect the battery ground cable.
8. Check the radio operation and adjust the antenna trimmer.

L-SERIES

Removal

1. Remove the control knobs and discs from the radio control shafts (Fig. 3).
2. Disengage the sun visors from the radio housing retaining slots.
3. Remove the four radio housing mounting screws.
4. Move the radio housing rearward to clear the control shafts, lower and disconnect the speaker plug connector and remove the radio housing.
5. Disconnect the radio power lead and the antenna lead-in cable.
6. Remove the control shaft nuts and washers attaching the radio to the radio front support brackets.
7. Support the radio assembly and remove the radio rear support screws.

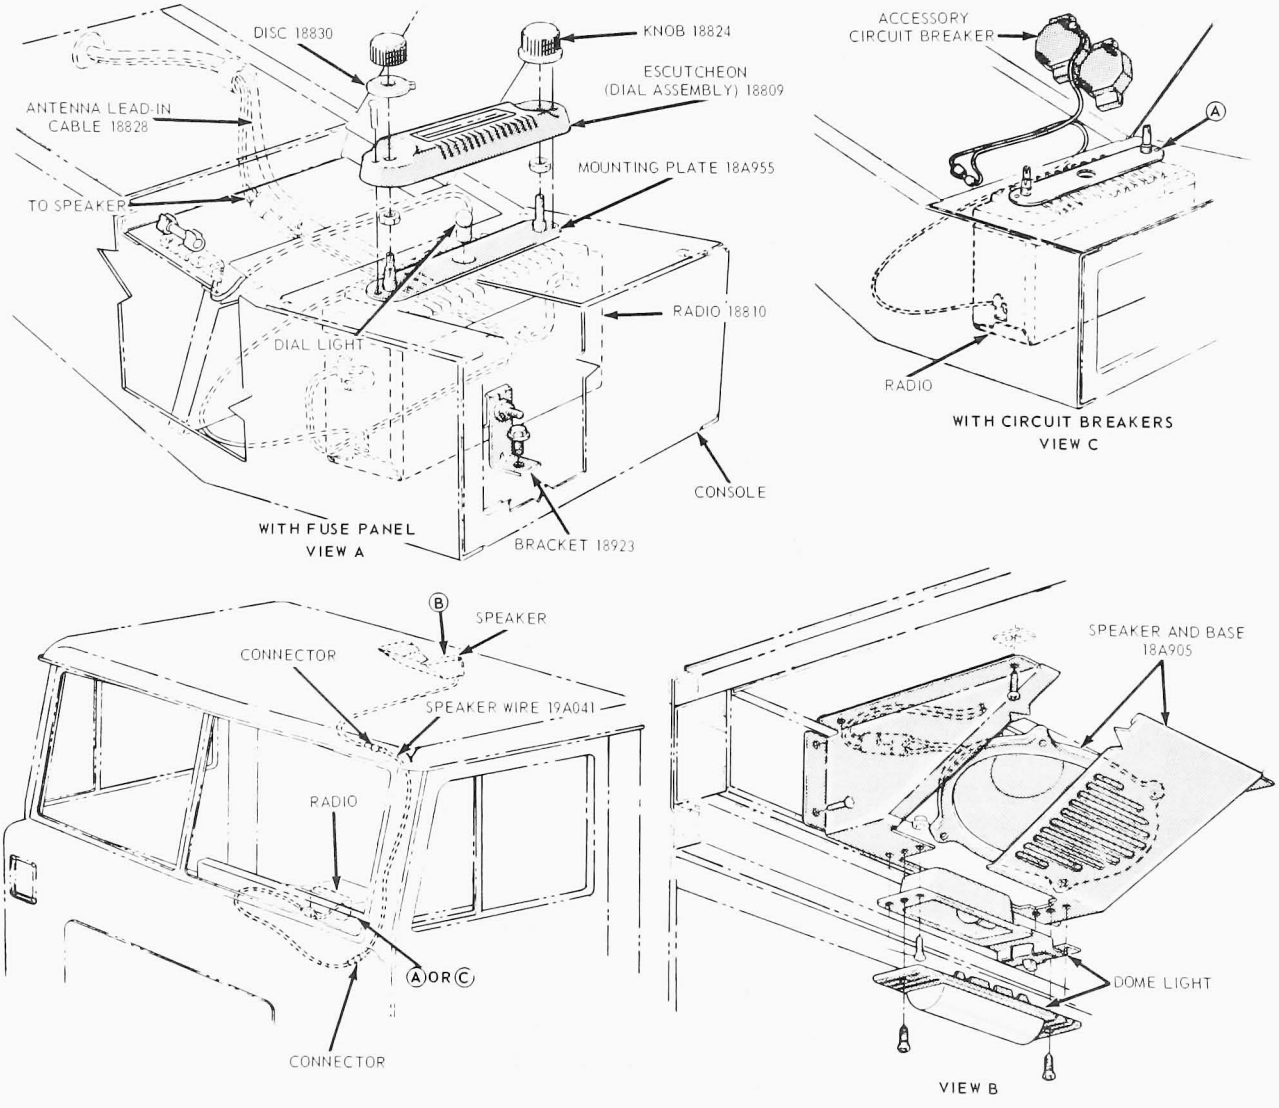

FIG. 4 Radio Installation—W-Series

8. Remove the radio assembly.

Installation

1. Position the radio assembly by inserting the control shafts into the radio front support bracket (Fig. 3).
2. Align the rear of the radio assembly and loosely install the rear support screws.
3. Install the control shaft nuts and washers and torque to specifications.
4. Tighten the rear support screws.
5. Connect the radio power lead and the antenna lead-in cable. **Do not operate the radio without the speaker connected, as it may damage the power transistor.**
6. Connect the speaker plug connector and if a new radio assembly is being installed, adjust the antenna trimmer. Refer to Adjustments.
7. Position the radio housing and install the four radio housing mounting screws. Torque the two mounting screws nearest the sun visor retaining slots to specifications.
8. Install the control knobs and discs.

C-SERIES

Removal

1. Disconnect the battery ground cable.
2. Disconnect the radio power lead, the antenna lead, and the speaker lead (Fig. 5).
3. Pull off the two control knobs. Remove the dial assembly attaching screws, and remove the dial assembly.
4. Remove the support bracket to instrument panel attaching screw.
5. Remove the retaining nuts, mounting plate, and remove the radio.
6. Remove the support bracket from the radio.

Installation

1. Install the support bracket on the radio.
2. Position the radio to the instrument panel (Fig. 5).
3. Position the mounting plate over the radio control shafts, and install the retaining nuts.
4. Install the dial assembly and control knobs. Rotate the tuning control to the clockwise stop to align the pointer with the tuner.
5. Install the radio support bracket attaching screw.
6. Connect the speaker lead, radio, power lead, and the antenna lead-in cable.
7. Connect the battery ground cable.
8. Check the operation of the radio and adjust the antenna trimmer.

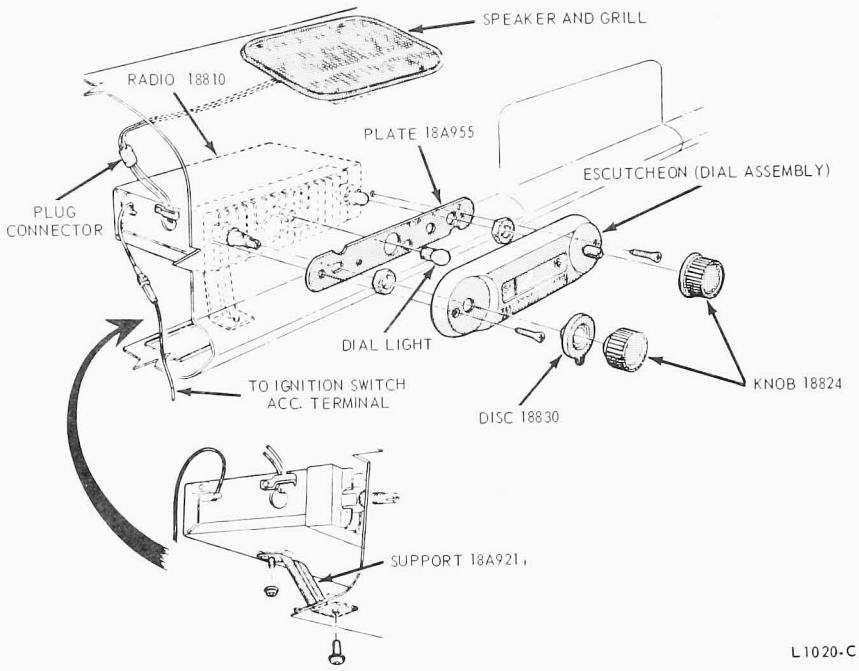

FIG. 5 Radio Installation—C-Series

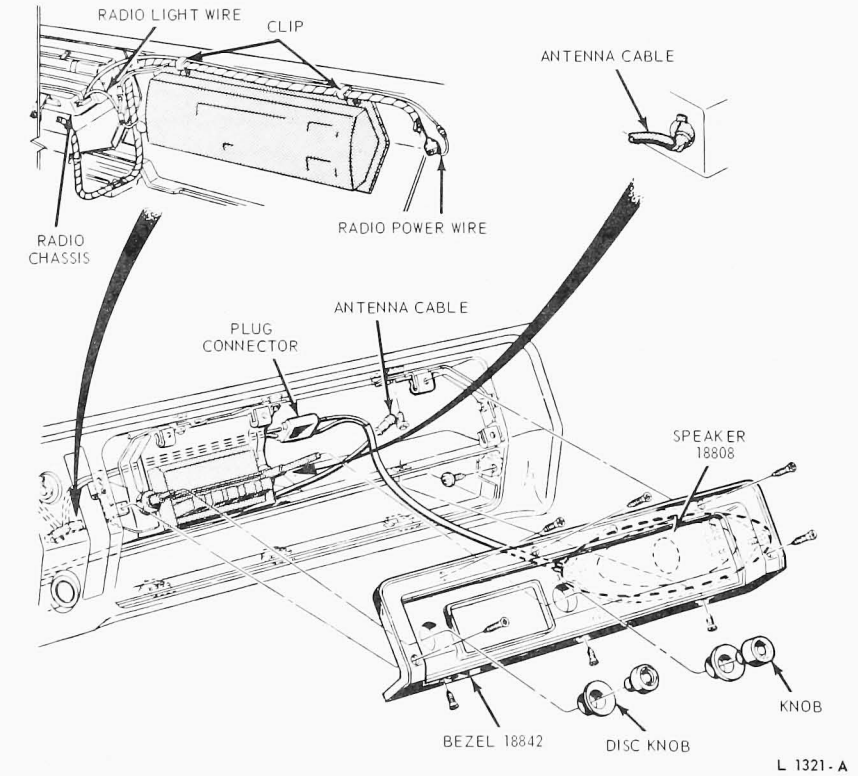

FIG. 6 Radio Installation—Econoline

ECONOLINE

Removal

1. Disconnect the ground cable from the battery.

2. Remove eight screws attaching the instrument cluster to the instrument panel. Pull the cluster away from the instrument panel and disconnect the speedometer cable from the speedometer. Allow the instrument cluster to hang out of the opening.
3. Disconnect the radio power and light wires at the connectors (Fig. 6).
4. From under the hood, remove the nut attaching the radio rear mounting bracket to the dash panel (Fig. 6).
5. Remove the knobs from the radio control shafts.
6. Remove eight screws attaching the radio bezel to the instrument panel. Pull the bezel away from the radio and disconnect the speaker wires at the multiple connector.
7. Remove the radio power wire from the two clips over the instrument cluster opening (Fig. 6).
8. Disconnect the antenna lead-in cable from the radio.
9. Remove three screws attaching the radio and mounting bracket to the radio opening, and remove the radio and bracket from the vehicle.
10. Remove the two nuts from the radio control shafts and remove the mounting bracket from the radio.

Installation

1. Position the mounting bracket to the front of the radio and install the two retaining nuts.
2. Position the radio and mounting bracket in the instrument panel opening. Route the power wire through the clips over the instrument cluster opening.
3. Install the three radio mounting bracket attaching screws.
4. Connect the antenna lead-in cable to the radio.
5. Connect the radio power and dial light wires at the connectors.

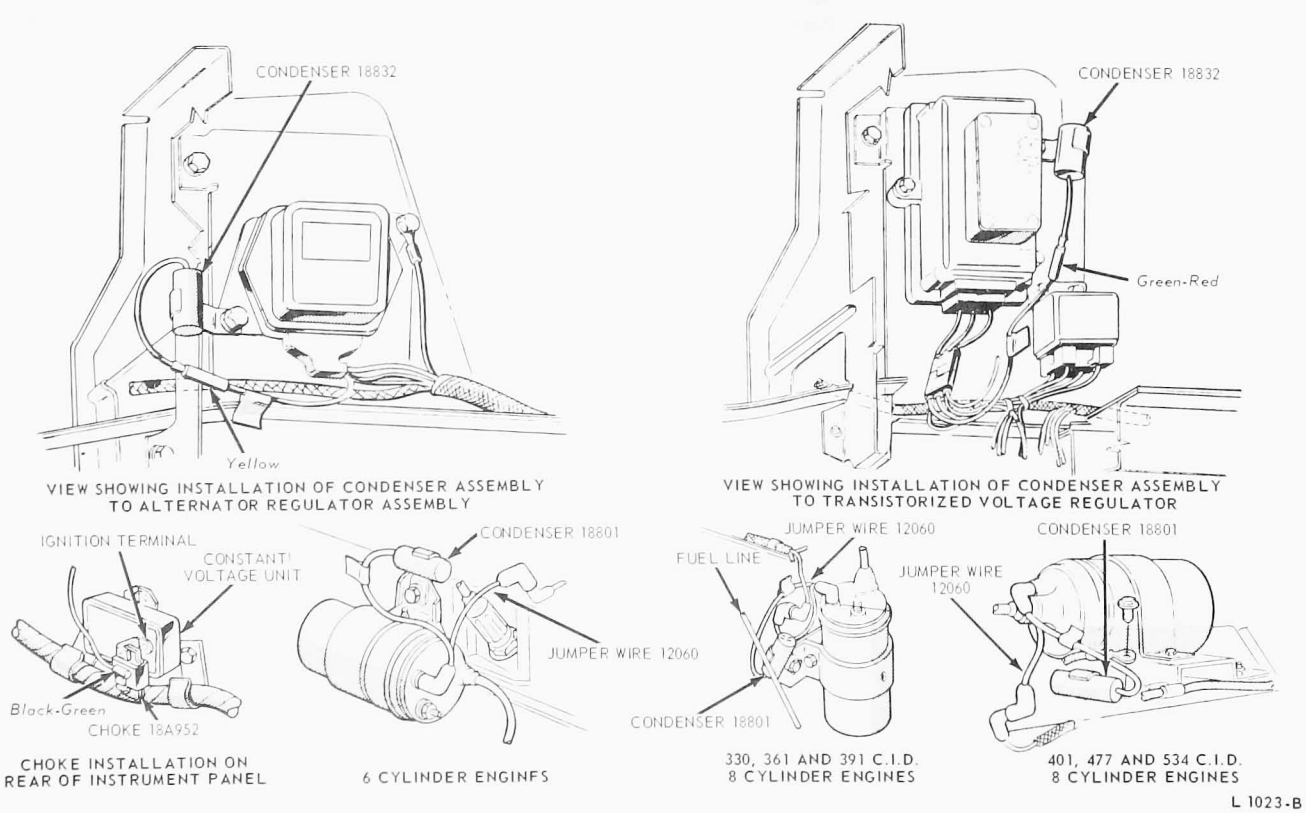

FIG. 10 Radio Suppression Equipment—C-Series

6. Connect the radio speaker wires and position the radio bezel to the radio opening. Install the eight bezel attaching screws.
7. Install the radio control knobs.
8. Connect the speedometer and install the instrument cluster.
9. Install the radio rear bracket attaching nut under the hood.
10. Connect the battery ground cable.
11. Check the operation of the radio and adjust the antenna trimmer.

BRONCO

Removal

1. Disconnect the radio lead wire at the fuse panel.
2. Disconnect the speaker leads at the receptacle on the underside of the radio chassis (Fig. 7).
3. Disconnect the antenna lead at the receptacle on the right side of the radio chassis.
4. Remove (pull) the volume control and the manual tuning control knobs from the shafts.
5. Remove the screws that retain the dial assembly to the instrument panel, and remove the dial assembly.
6. Remove the retaining nuts and the retaining plate that secure the radio to the instrument panel.
7. Remove the radio bottom support bracket retaining screw and remove the radio assembly from the instrument panel.

Installation

1. Position the radio to the inner side of the instrument panel, and install the right and left support bracket to radio retaining nuts (Fig. 7).
2. Position the retaining plate to the outer side of the instrument panel over the pilot light and control shafts, and install the retaining nuts.
3. Position the dial assembly, install the retaining screw, and seat the control knobs on the control shafts.
4. Connect the speaker leads, the antenna lead, and the radio power lead wire at the fuse panel.
5. Calibrate the dial pointer with the tuner by rotating the tuning knob until the dial pointer reaches the end of its travel at the right side of the dial.
6. Check the operation of the radio and adjust the antenna trimmer.

W-SERIES

Removal

1. Disconnect the battery ground cable.
2. Remove the control knobs and disc from the radio.
3. Remove the dial assembly attaching screws and remove the dial assembly (Fig. 4).
4. Remove the control shaft retaining nuts and remove the dial mounting plate.
5. Remove the console cover and disconnect the radio power lead, speaker leads, and the antenna lead-in cable.
6. Loosen the support bracket-to-radio retaining nut, and remove the radio.

Installation

1. Position the radio to the console and support bracket. Position the radio to fit flush against the console cover, and tighten the support bracket retaining nut (Fig. 4).
2. Connect the radio power lead, speaker leads, and the antenna lead-in cable.
3. Connect the battery ground cable.
4. Turn the radio ON and adjust the antenna trimmer, if required.
5. Install the console top cover.
6. Position the dial mounting plate over the control shafts and install the retaining nuts.
7. Install the dial assembly, disc, and knobs. Rotate the tuning control to the clockwise stop. This will align the dial pointer with the tuner.

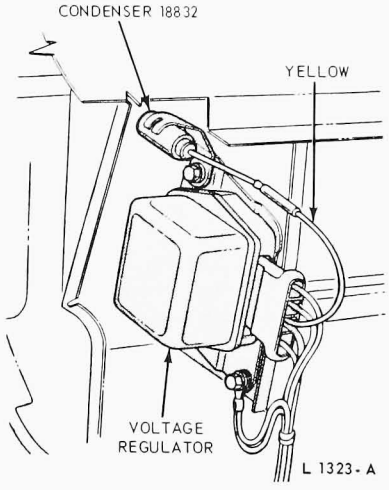

FIG. 11 Radio Suppression Equipment—Econoline

RADIO SUPPRESSION EQUIPMENT

The radio suppression equipment used on the different models is shown in Figs. 8 thru 13. When replacing any radio suppression equipment components, be sure that a good contact is made at all attachments. Remove any paint or dirt from between a condenser and its ground. Tighten all nuts and bolts securely.

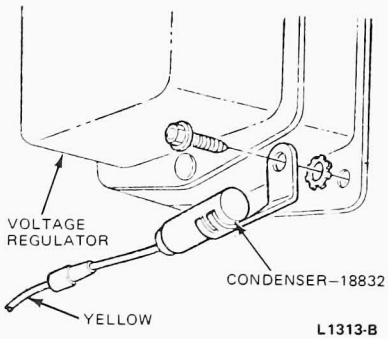

FIG. 12 Radio Suppression Equipment—Bronco

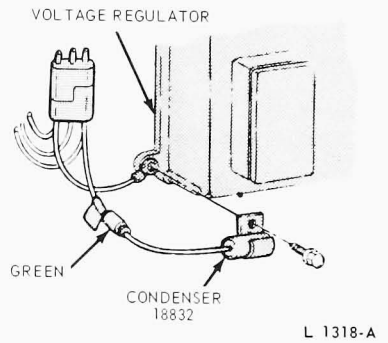

FIG. 13 Radio Suppression Equipment—W-Series

PART 35-11 Antennas

REMOVAL AND INSTALLATION

ANTENNA

F-SERIES

Removal

1. Disconnect the antenna lead-in cable from the radio (Figs. 1 and 2).
2. Disengage the cable from the three clips along the lower edge of the instrument panel.
3. Unsnap the cap from the antenna base and remove the cap.
4. Remove four antenna attaching screws and remove the antenna and lead-in cable from the vehicle.

Installation

1. Place the mounting pad on the cowl panel over the antenna opening (Figs. 1 and 2).
2. Insert the antenna lead-in cable into the antenna hole in the cowl and through the grommet until the antenna base is seated on the cowl. **The grommet must be firmly seated to prevent air and water leakage.**
3. Install the four antenna attaching screws.
4. Place the cap in position over the antenna base and snap the cap onto the base.
5. Route the antenna lead-in cable along the lower edge of the instrument panel and place in the three clips.
6. Connect the antenna lead-in cable to the radio and check the radio operation.

L-SERIES

Removal

1. Remove the headlining trim panel and the radio housing.
2. Disconnect the antenna lead-in cable from the radio (Fig. 3).
3. Unscrew and remove the antenna rod assembly.
4. Support the base and cable assembly and remove the stanchion nut, stanchion and gasket.
5. Remove the base and cable assembly, collar and insulator.

Installation

1. Position the collar and insulator on the base and cable assembly (Fig. 3).
2. Insert the base and cable assembly, collar and insulator into the drilled antenna opening.
3. Install the gasket, stanchion and stanchion nut.
4. Thread the rod assembly onto the base assembly and torque to 35-50 in-lbs.
5. Install the headlining trim panel.
6. Plug the antenna lead-in cable into the radio assembly and adjust the antenna trimmer.
7. Install the radio housing.

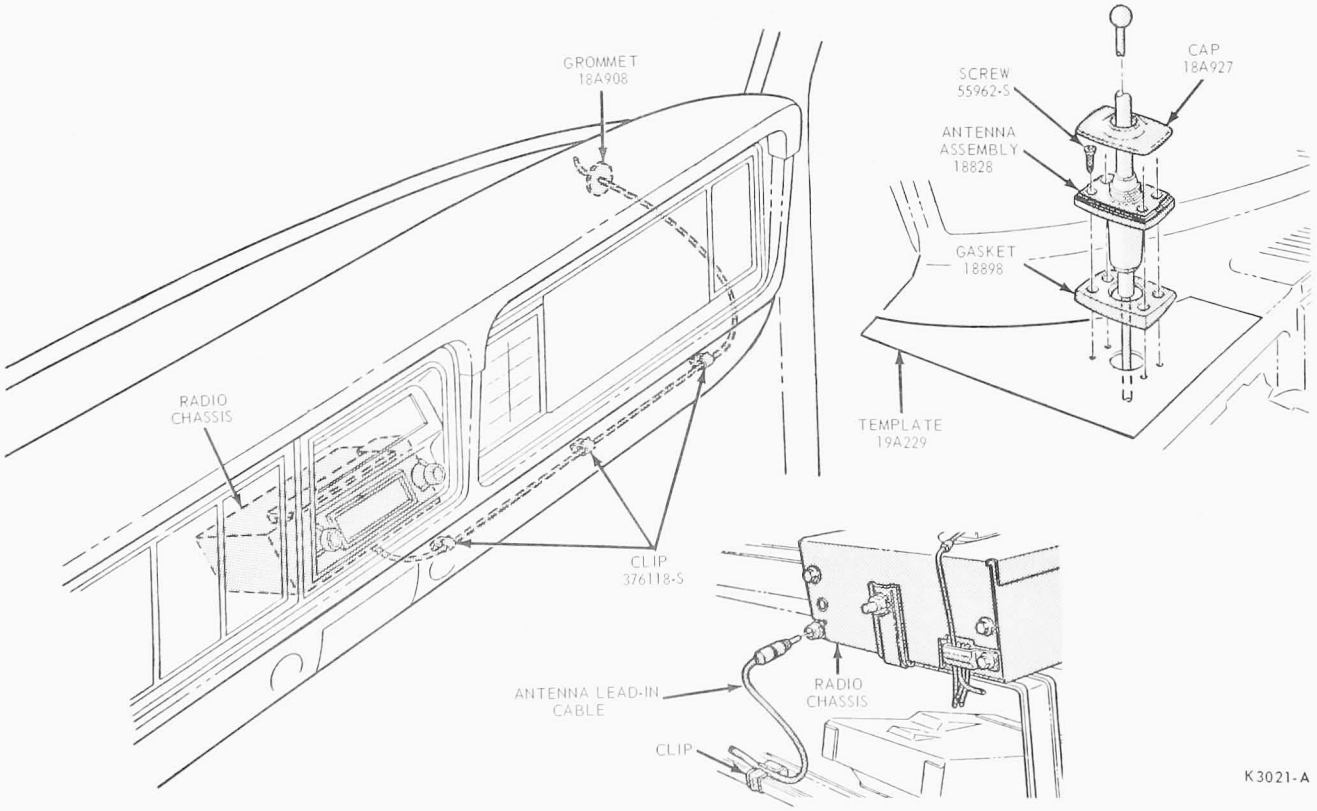

FIG. 1 Antenna Installation—F-100 Through F-350 the radio (Figs. 1 and 2).

C-SERIES

The tilt cab antenna is installed from the underside of the cowl.

Removal

1. Disconnect the antenna lead-in cable from the radio.
2. Remove the mounting nut and stanchion assembly (Fig. 4).
3. Push the antenna base out through the right hand door upper hinge opening.
4. Remove the antenna and lead-in cable.

Installation

1. Insert the tip of the new antenna through the right hand door upper-hinge opening and through the antenna mounting hole (Fig. 4).
2. Pull the antenna into position. Install the stanchion and nut. Tighten the nut to 15 in-lbs torque.
3. Route the antenna lead through the opening under the instrument panel, and plug the connector into the antenna socket of the radio chassis. Seat the cable grommet into the hole in the cowl.
4. Check the operation of the radio and adjust the antenna trimmer.

W-SERIES

Removal

1. Disconnect the antenna lead-in cable from the antenna (Fig. 5).
2. Remove the two nuts, washers, and insulator attaching the antenna to the cab and remove the antenna.

Installation

1. Position the antenna to the cab and install the insulator, washers, and nuts (Fig. 5).
2. Connect the lead-in cable to the antenna.
3. Check the operation of the radio and adjust the antenna trimmer.

ECONOLINE

Removal

1. Disconnect the antenna lead from the radio receiver cable (Fig. 6).
2. Pull the antenna lead through the grommet located under the dash panel.
3. Remove the grommet from the side cowl panel.
4. Remove the antenna mounting nut and stanchion.
5. Remove the antenna and retainer assembly from the vehicle.

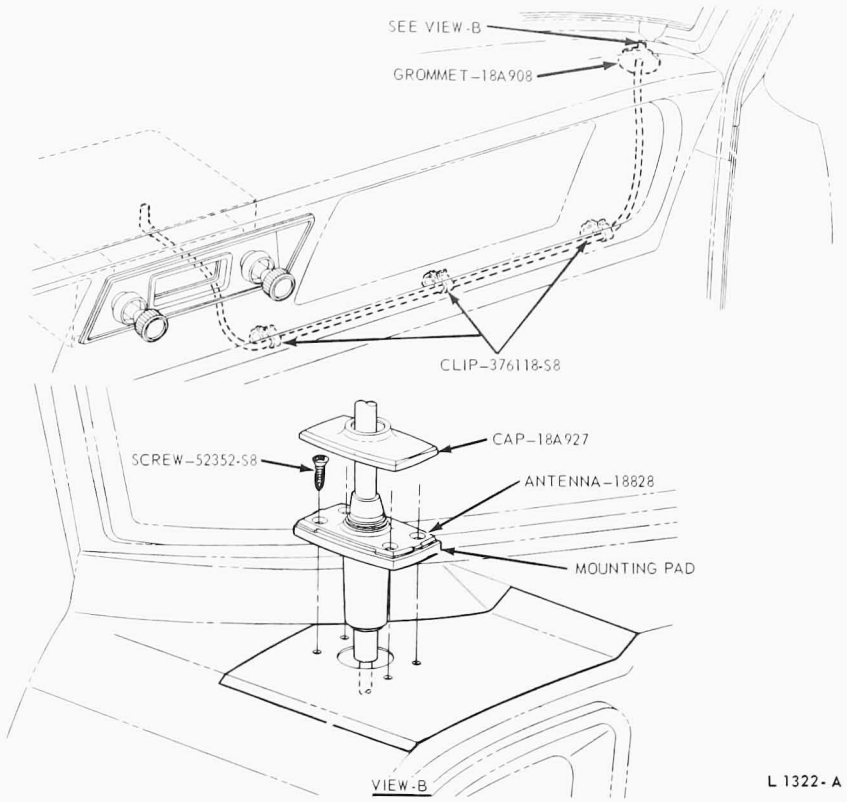

FIG. 2 Antenna Installation—F-500 Through F-750

Installation

1. Feed the antenna lead through the antenna mounting opening, side cowl panel and through the grommet located under the dash panel.
2. Connect the antenna lead to the radio receiver cable.
3. Position the grommet which is part of the antenna lead in the side cowl panel. Pull in hard on the lead to seat the grommet.
4. Position the antenna, antenna retainer and stanchion and install the mounting nut.
5. Check the operation of the radio and adjust the antenna trimmer.

BRONCO

Removal

1. Remove the bolt and nut retaining the antenna to the mounting bracket (Fig. 7).
2. Remove the nut and stanchion assembly.
3. Disconnect the antenna lead from the radio. Pull the lead back to the cowl.
4. Remove the antenna from the underside of the fender.

Installation

1. Position the antenna from the underside of the fender. Install the stanchion assembly and start the nut (Fig. 7).
2. Position the antenna in the mounting bracket, tighten the stanchion nut and install the bolt and nut in the mounting bracket.
3. Feed the lead through the cowl. Route the lead behind the steering column wire harness and over the steering column to the radio.
4. Plug the antenna into the radio chassis and check the operation of the radio.
5. Adjust the antenna trimmer.

A page number indicates that the item is for the vehicle(s) listed at the head of the column.

DESCRIPTION

SPEAKER DESCRIPTION

The radio speakers used in all vehicles have 3.2 ohms impedance. The new speakers are not interchangeable with the 8 ohm speakers used before 1972.

REMOVAL AND INSTALLATION

SPEAKER

F-100 THROUGH F-350

AM Radio Without Air Conditioning

1. Disconnect the speaker wires at the connector behind the radio.**Do not operate the radio with the speaker disconnected.**
2. Remove two screws attaching the speaker to the instrument panel (Fig. 1), and remove the speaker from under the instrument panel.
3. To install, position the speaker to the underside of the instrument panel and install the two attaching screws.
4. Connect the speaker wires to the radio and check the operation of the speaker.

AM Radio with Air Conditioning

1. Disconnect the speaker wires at the connector behind the radio.**Do not operate the radio with the speaker disconnected.**
2. Remove the two grille assembly retaining screws (Fig. 1).
3. Remove two plate assembly attaching screws and lift the plate and speaker from the instrument panel. Then, remove the speaker from the plate assembly (Fig. 1).
4. To install, assemble the speaker to the plate assembly. Then install the plate attaching screws and the grille.
5. Connect the speaker wires, and check the speaker operation.

AM-FM Radio

1. Remove the door trim panel and watershield.
2. Disconnect the speaker wires at the connector (Fig. 1).**Do not operate the radio with speakers disconnected.**
3. Remove four speaker attaching screws and remove the speaker.
4. To install, connect the speaker wires at the connector. Then, position the speaker to the door and install the attaching screws.
5. Check the speaker operation. Then, install the watershield and door trim panel.

F-500 THROUGH F-750

Removal

1. Disconnect the speaker wires at the connector (Fig. 2).**Do not operate the radio with the speaker disconnected.**
2. Remove the radio from the instrument panel.
3. Remove the speaker bracket retaining screw at the radio opening.
4. Remove the speaker bracket and speaker from the vehicle.

Installation

1. Position the speaker and speaker bracket to the instrument panel and install the bracket retaining screw (Fig. 2).
2. Install the radio.
3. Connect the speaker wires to the radio at the connector and check the operation of the radio and speaker.

L-SERIES

Removal

1. Remove the radio chassis housing from the roof panel.
2. Disconnect the speaker plug connector (Fig. 3).**Do not operate the radio when the speaker is disconnected.**
3. Remove the two speaker mounting nuts.
4. Remove the speaker.

Installation

1. Position the speaker on the radio chassis housing speaker mounting screws (Fig. 3).
2. Install the two speaker mounting nuts.
3. Connect the speaker plug connector.
4. Install he radio chassis on the roof panel.

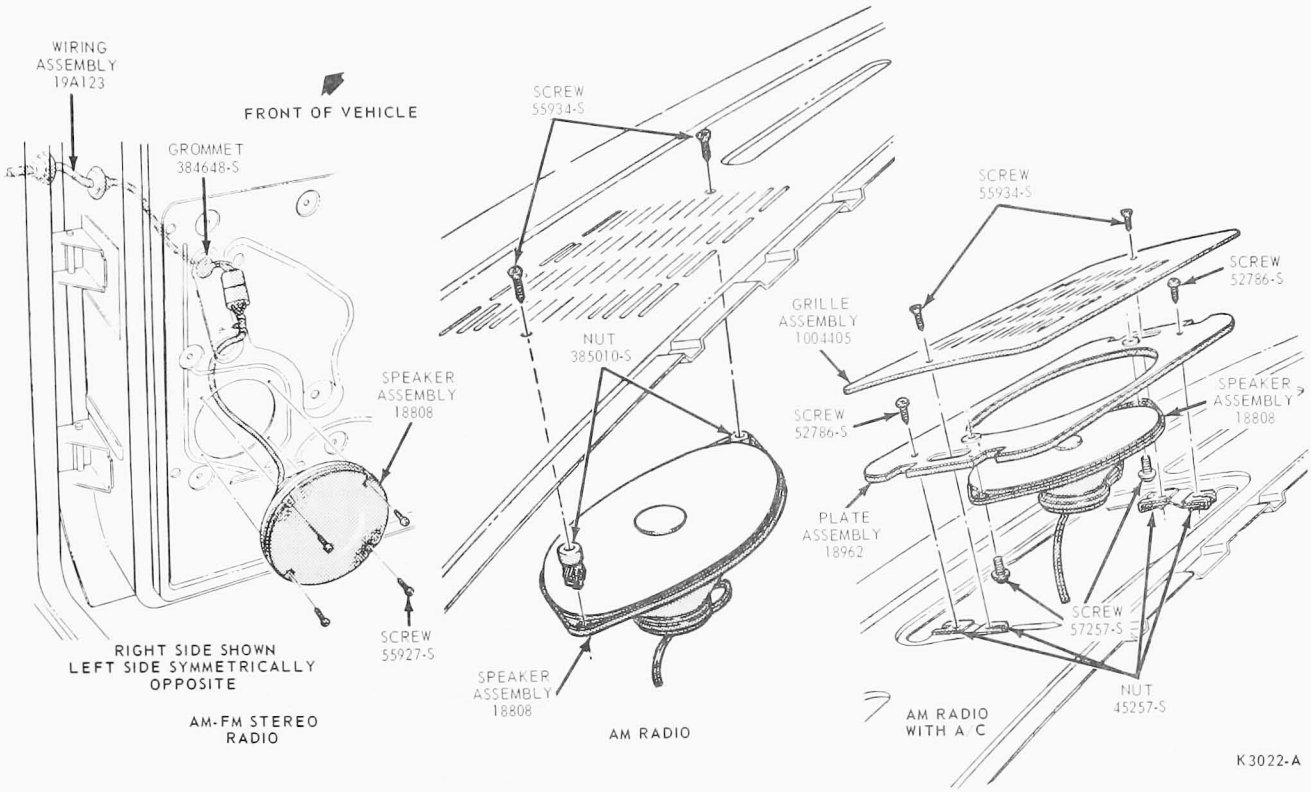

FIG. 1 Radio Speaker Installation—F-100 Through F-350

C-SERIES

Removal

1. Remove the four speaker mounting screws and wing-nuts (Fig. 4).
2. Disconnect the speaker plug connector. **Do not operate the radio when the speaker is disconnected.**
3. Remove the speaker.

Installation

1. Position the speaker under the instrument panel (Fig. 4).
2. Install the four speaker mounting screws and wing-nuts.
3. Connect the speaker plug connector.

W-SERIES

Removal

1. Remove eight screws attaching the speaker and base to the roof panel (Fig. 5).
2. Lower the speaker and base and disconnect the speaker and dome light wires at the connectors. **Do not operate the radio when the speaker is disconnected.**
3. Remove four screws attaching the speaker to the base, and remove the speaker.

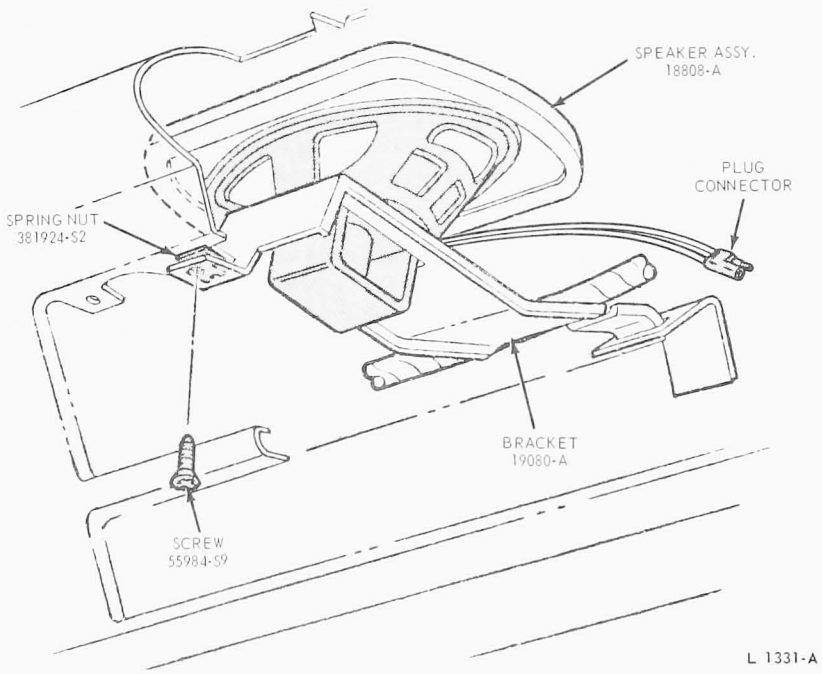

FIG. 2 Speaker Installation—F-Series

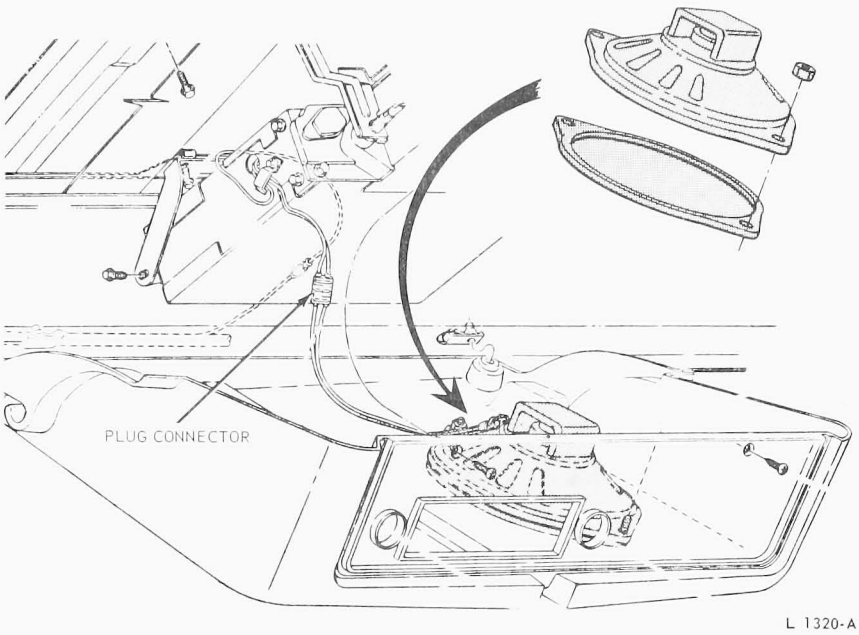

FIG. 3 Speaker Installation—L-Series

Installation

1. Position the speaker to the base, and install the four attaching screws (Fig. 5).
2. Connect the speaker and dome light wires and position the speaker and base to the roof panel.
3. Install the eight speaker and base attaching screws, and check the operation of the speaker.

ECONOLINE

Removal

1. Pull the radio control knobs off the radio control shafts.
2. Remove eight screws attaching the radio bezel to the instrument panel (Fig. 6).
3. Pull the bezel away from the radio, and disconnect the speaker wires at the multiple connector. **Do not operate the radio when the speaker is disconnected.**

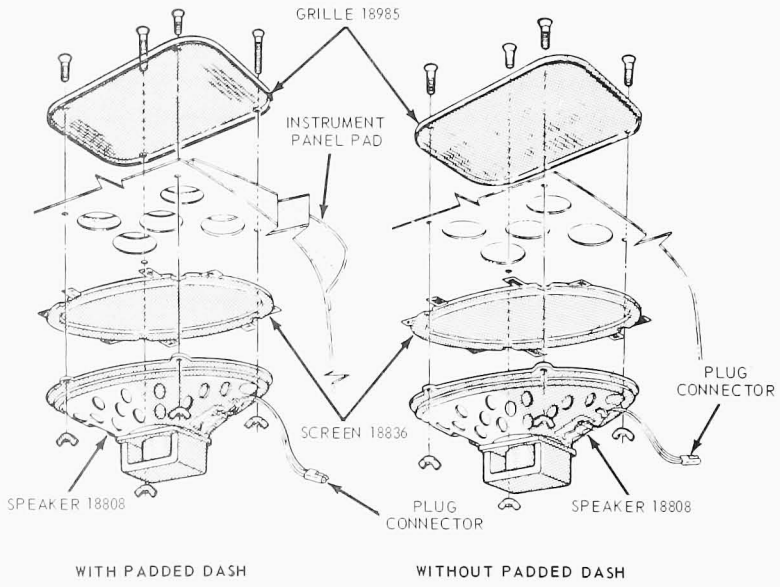

FIG. 4 Speaker Installation—C-Series

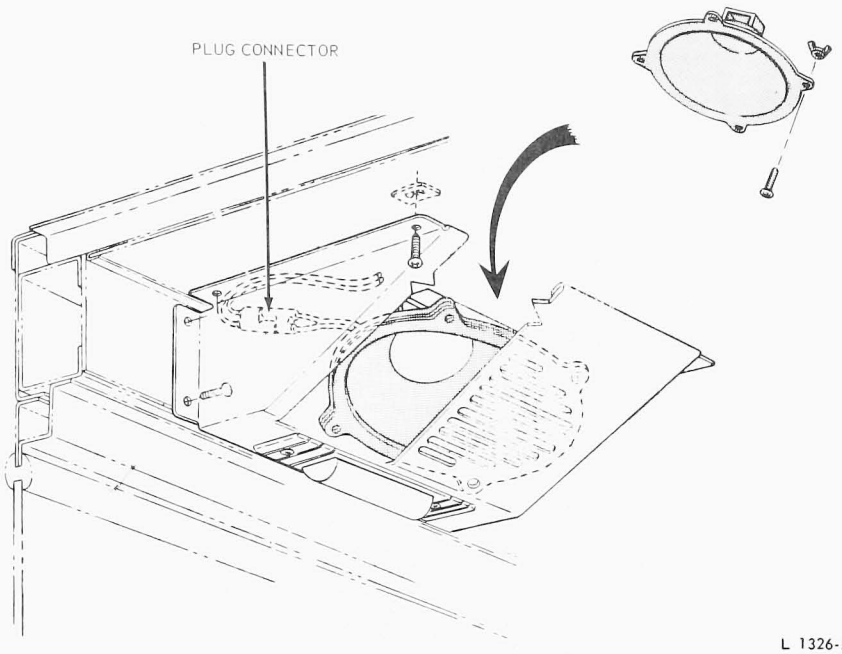

FIG. 5 Speaker Installation—W-Series

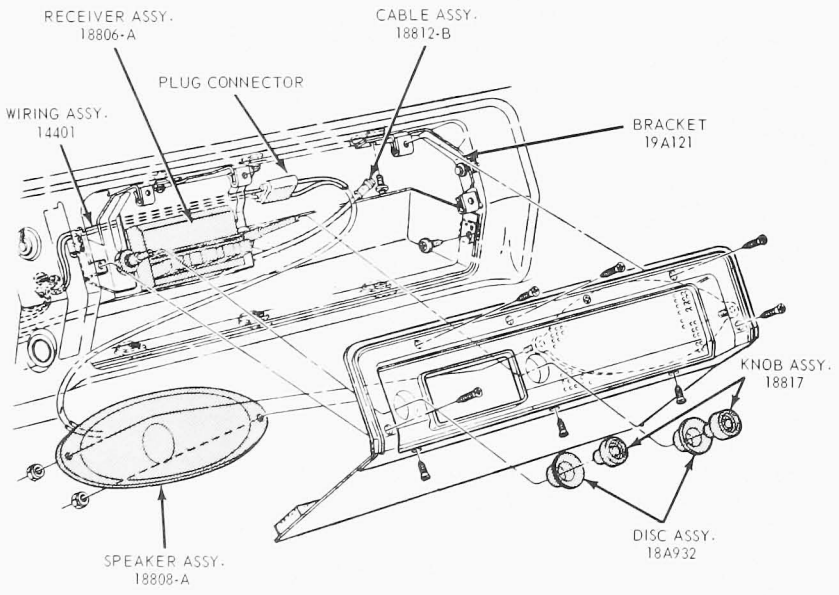

FIG. 6 Speaker Installation—Econoline

4. Remove two nuts attaching the speaker to the radio bezel and remove the speaker.

Installation

1. Position he radio speaker to the bezel and install the attaching nuts (Fig. 6).
2. Position the bezel to the radio, and connect the speaker wires at the multiple connector.
3. Install the eight radio bezel attaching screws and the radio control knobs.

BRONCO

Removal

1. Disconnect the speaker leads from the receptacle on the underside of the radio chassis.

Do not operate the radio when the speaker is disconnected.

2. Remove the speaker retaining screws (Fig. 7). and the speaker mounting board and speaker from the instrument panel.

Installation

1. Position the replacement speaker and mounting board to the instrument panel, and install the speaker retaining screws (Fig. 7).
2. Connect the speaker lead wires to the receptacle and check the operation of the radio.

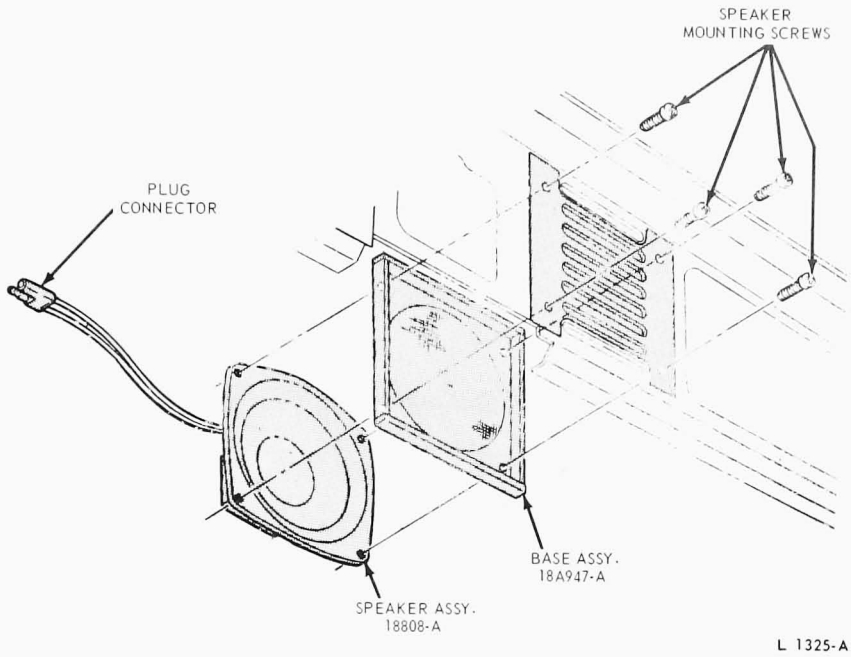

FIG. 7 Speaker Installation—Bronco

PART 35-40 Ash Receptacles and Cigar Lighter

REMOVAL AND INSTALLATION

ASH RECEPTACLES

Ash receptacle shield assemblies that retain the ash receptacles may be easily removed by first removing the ash receptacle. The shield assembly may then be removed by removing the shield assembly mounting screws.

CIGAR LIGHTERS

1. Disconnect he battery ground cable.
2. Remove the lighter element (Fig. 1).
3. Disconnect the push-on connector from the base of the lighter socket.
4. Remove the illuminating lamp socket (if so equipped) from the side of the lighter socket retainer by depressing both sides of the illuminating lamp socket and pulling away from the lighter socket retainer.
5. Unscrew and remove the socket retainer.
6. Remove the socket from the front of the instrument panel.

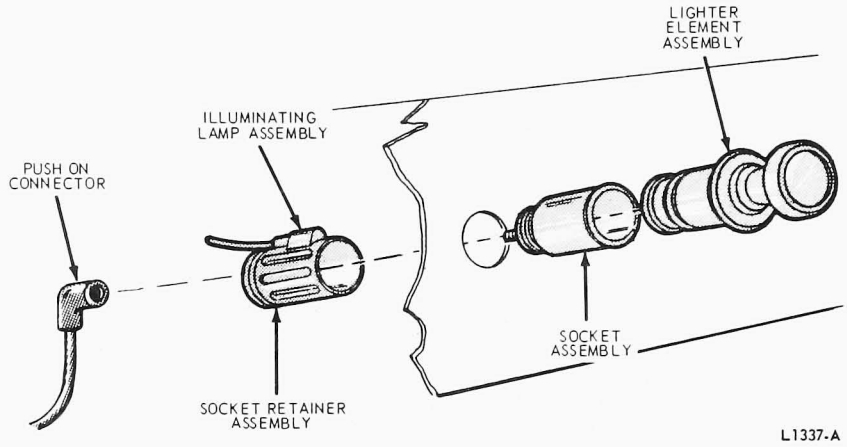

FIG. 1 Cigar Lighter Installation

PART 35-50 Mirrors—Inside and Outside

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION		REMOVAL AND INSTALLATION - Cont.	
Inside Rear View Mirror	50-01	Remote Control Rear View Mirror	50-01
Outside Rear View Mirror	50-01		

REMOVAL AND INSTALLATION

INSIDE REAR VIEW MIRROR

Mirror Removal

1. Loosen the mirror assembly-to-mounting bracket set screw (Fig. 1).
2. Remove the mirror assembly by sliding upward and away from the mounting bracket.

Mounting Bracket Installation

1. Locate and mark the mirror mounting bracket location on the outside surface of the windshield with a wax pencil (Fig. 1).
2. Thoroughly clean the inside of the windshield with mild abrasive cleaning powder and a clean cloth saturated in alcohol. Then, use a paper towel and remove all cleaner from the windshield.
3. Roughen the bonding surface of the mounting bracket with fine grit sandpaper. Then, wipe the surface clean with a paper towel soaked in alcohol.
4. Using the applicator, apply a generous amount of Loctite Minute Bond Accelerator to the bonding surface of the mounting bracket. Allow the bonding material to dry for five minutes. Do not touch the mounting surface.
5. Apply a **thin** film of Accelerator to the mounting surface of the windshield. Allow the bonding material to dry for one minute.
6. Apply two drops of Loctite Minute Bond to the mounting surface of the bracket. Using a clean toothpick or wooden match, quickly spread the adhesive evenly over the mounting surface of the bracket.
7. Quickly position the mounting bracket on the windshield. The 3/8 inch circular depression in the bracket must be toward the bottom edge. Press the bracket against the windshield for about one minute.

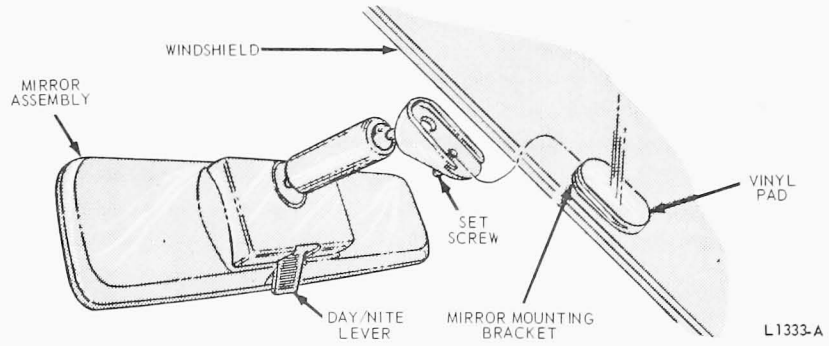

FIG. 1 Inside Rear View Mirror Installation

8. Allow the bond to set for five minutes. Then, remove any excess bonding material from the windshield with an alcohol dampened rag.

Mirror Installation

Attach the mirror to the mounting bracket and tighten the set screw to 5-15 in-lb.

OUTSIDE REAR VIEW MIRROR

CONVENTIONAL TYPE—BRONCO, ECONOLINE AND F-100-350

The conventional outside rear view mirror is mounted on the door. To remove the mirror, remove the attaching screws and lift off the mirror and gasket (Fig. 2).

WESTERN TYPE

The western type outside rear view mirrors (Fig. 3) are usually mounted on both doors. The mirrors may be removed from the mounting bracket by removing the attaching nuts.

MOUNTING BRACKETS

The mounting brackets are removed by removing either the mounting bracket stud nuts or by removing the mounting bracket screws (Fig. 4).

REMOTE CONTROL REAR VIEW MIRROR

Removal

1. Remove the bezel nut from the remote control actuator (Fig. 5).
2. Attach a pull cord to the remote control actuator.
3. Remove two mirror attaching screws and remove the mirror and control cables from the door. When the cables are out of the door, disconnect the pull cord from the remote control actuator. **Do not allow the pull cord end to be pulled into the door.**

Installation

1. Attach the pull cord to the remote control actuator.
2. Position the mirror to the door using the pull cord to route the cables and actuator through the door.
3. Install the two mirror attaching screws (Fig. 5).
4. Pull the remote control actuator through the hole in the door trim panel and install the bezel nut on the

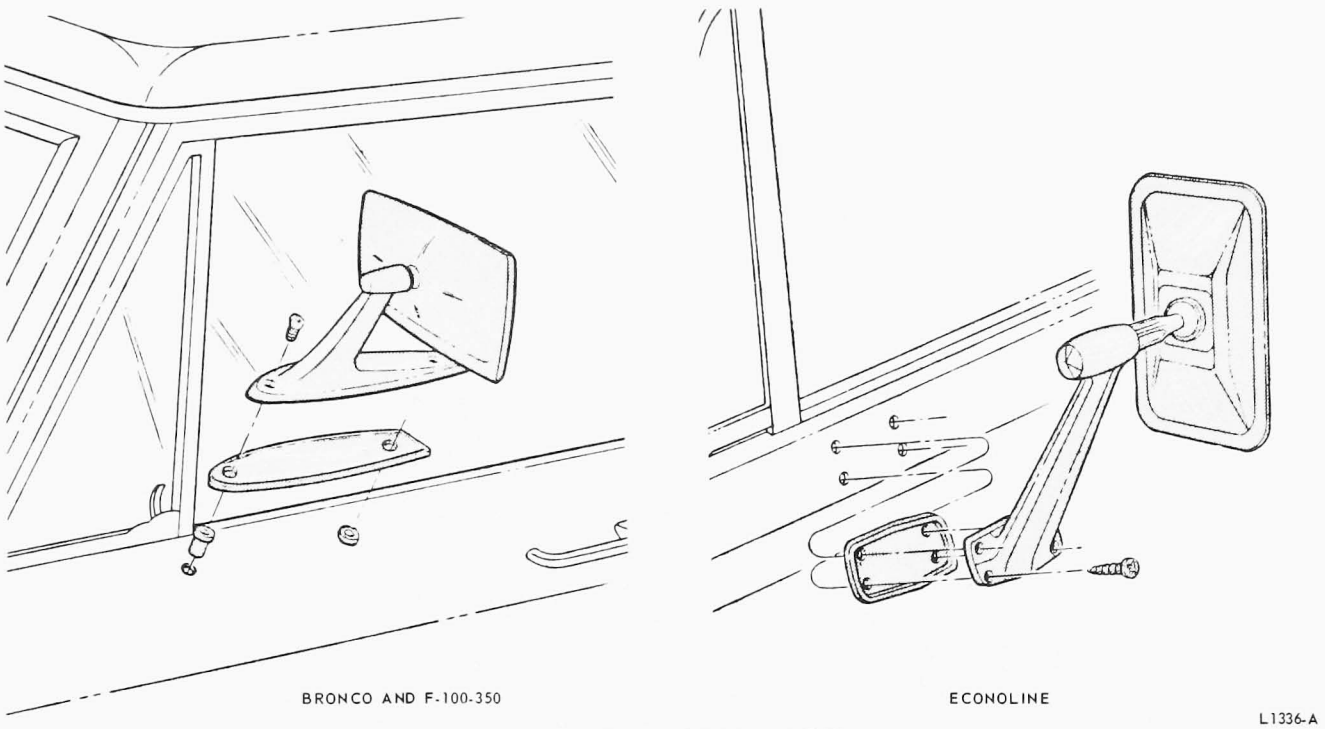

FIG. 2 Conventional Outside Mirror—Bronco, Econoline and F-100—F-350

actuator.

5. Remove the pull cord from the actuator and check the operation of the mirror.

DESCRIPTION AND OPERATION

All trucks with hydraulic brakes are equipped with two-speed electric wiper motors. Trucks with air brakes are equipped with an air pressure operated motor.

Two independent two-speed motors are used on tilt-cab trucks. They are connected together and connected to the wiper control switch by an intermediate wiring harness. The quick-disconnect plug is a part of the wiring harness.

The two-speed, permanent magnet, three brush electric windshield wiper motor (excluding L-Series truck wiper motors) has a brush rigging that permits selection of low or high speed. When the control selector is in low position, the grounded brush and the white wire brush are used, and the motor operates at low speed. When the control selector is in high position, the grounded brush and the blue wire brush are used. Current by-passes a portion of the armature winding, causing the motor to run faster. When the control selector is moved to the park position, the motor will continue at low speed until the park switch lower contacts open, stopping the motor in the park position.

Intermittent Wipers

Optional intermittent wipers are available on F-100 through F-350 trucks. This system is a two-speed wiper system with an intermittent feature. For normal wiper operation, turn the wiper control knob to the right to any one of two detents (Low and High speed).

For intermittent operation of the wiper switch, rotate the wiper control knob to the left. The more the knob is rotated to the left, the longer the time interval between wiper blade sweeps.

The governor for the intermittent wiper system is mounted on the lower flange of the instrument panel below the wiper-washer switch.

TESTING

WIPER MOTOR CURRENT DRAW

EXCEPT L-SERIES

Disconnect the linkage from the motor and disconnect the electrical plug to test the motor on the vehicle. Connect the green lead from the test equipment to the battery positive (plus) post (Fig. 1). Connect the positive (red) lead from the tester first to the low speed connection and then to the high speed connections at the connector plug as shown. In either case, the current draw should not exceed 3 amperes.

L-SERIES

The windshield Wiper Motor Tests can be performed with the wiper motor installed in the vehicle with linkage disconnected or on the bench.

The motor terminals are too small to make the necessary test connections without using connector sleeves and wires between the motor terminals and the test equipment as shown in Fig. 2. The connector sleeves (available in Kit No. C4AZ-14294-B) should be crimped onto both ends of the wires.

Connect the positive (red) lead from the test equipment to the center terminal on the motor end plate, and connect the green lead from the tester to the battery positive post (Fig. 2). Connect a jumper wire from the battery negative post to the low speed terminal on the motor end plate and read the current draw. Move the jumper wire from the low speed terminal to the high speed terminal, and read the high speed current draw. In either case the current draw should not exceed 3.5 amperes. If the current draw does exceed 3.5 amperes, check the output arm and windlatch mechanism for binding or damage before replacing the motor.

CIRCUIT BREAKER TEST

The circuit breaker is located in the wiper control switch.

All pin terminal switches have a circuit breaker rating of 8 1/4 amps and

all blade terminal switches have a rating of 7 amps.

Two separate tests are necessary to check for correct circuit breaker operation.

Test 1

1. Before connecting the switch to the Rotunda volt-amp tester as shown in Fig. 3, short the tester leads together and adjust the current draw until it equals the circuit breaker rating.
2. Connect the switch to the tester as shown in Fig. 3. Leave the switch connected to the tester for ten minutes. The current reading on the ammeter should remain at the rated current. If the circuit breaker opens during the ten minutes, replace the wiper switch assembly.

Test 2

1. Short the tester leads together and adjust the current draw until it is twice the rated current.
2. Connect the switch as shown in Fig. 3. The current reading on the ammeter should drop to zero within 30 seconds. If it takes longer than 30 seconds for the circuit breaker to open (current reading drops to zero) replace the wiper switch assembly.

WIPER SWITCH CONTINUITY TEST

Check the continuity between the switch terminals as shown in Figs. 4 and 5. Either a self-powered test light or an ohmmeter can be used to test a standard two speed switch. An ohmmeter must be used to test a switch used with the intermittent wiper system.

To detect marginal operation of the switch, rotate the switch control knob while each reading is being taken.

If the switch does not exhibit continuity as shown in Figs. 4 and 5, or if poor continuity exists in any switch position, replace the switch.

WINDSHIELD WIPER INTERMITTENT GOVERNOR TEST

F-100 THROUGH F-350

If intermittent operation is unsatisfactory, first check the motor current draw and the control switch and all connecting wires for continuity. If the motor, switch and connecting wires are OK, replace the electronic governor.

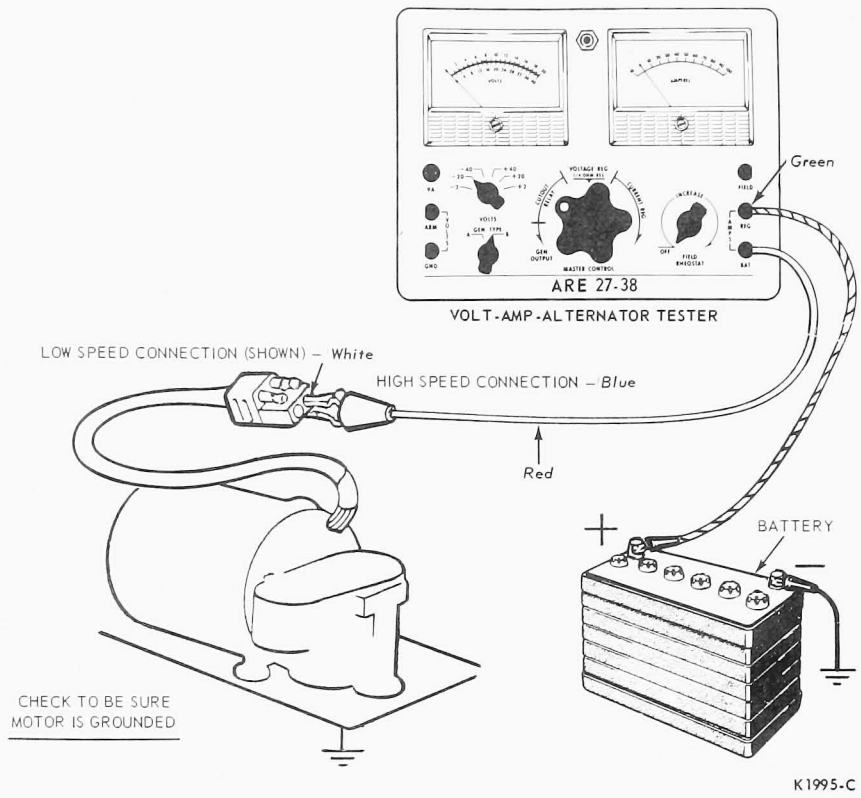

FIG. 1 Wiper Motor Current Draw Test

PAKING TEST—ELECTRIC

Stop the wiper system with the ignition switch so that the wiper blades are not in park position. Connect jumper wires as shown in Fig. 5. The wipers should not run more than one full cycle and then park. If the motor will not park or will not run to park position, replace the park switch. If the motor stops correctly check the windshield wiper manual control switch and the wiring for continuity.

ADJUSTMENTS

ARM AND BLADE ASSEMBLY

Remove the arm and blade assemblies from the pivot shafts. Turn on the wiper switch, allow the motor to move the pivot shafts three or four cycles, and then turn off the wiper switch. This will place the pivot shafts in park position.

Install the arm and blade assemblies on the pivot shafts to dimension X as shown in Fig. 7. Dimension X is the distance between the centerline of the blade saddle and the edge of the glass. The value of Dimension X for each vehicle is given in Fig. 8.

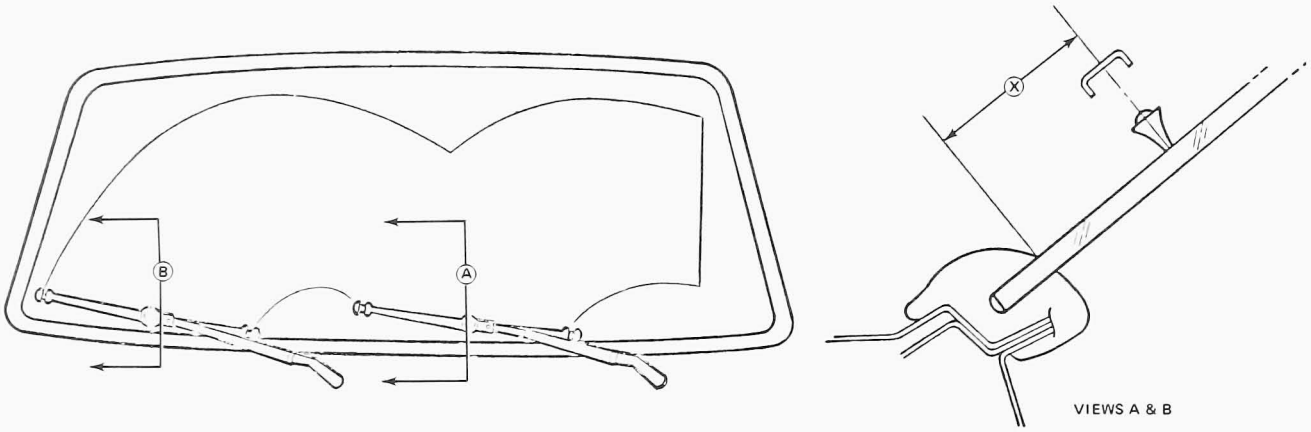

FIG. 7 Wiper Arm and Blade Adjustment

REMOVAL AND INSTALLATION

WIPER MOTOR

BRONCO

The motor and bracket assembly is mounted on the left side of the windshield header. To remove the motor, it will be necessary first to remove the cover and disconnect the linkage arm and pivot shaft assembly from the motor drive arm by removing the retaining clip (Fig. 9). Disconnect the motor wires at the multiple connector. Remove the two bolts and nuts that attach the motor mounting bracket to the windshield header, and remove the bracket and motor assembly.

When installing the motor, tighten the motor bracket-to-windshield header bolts to torque of 48-72 in-lbs and tighten the nuts to 20-30 in-lbs. Then, install the cover.

C-SERIES

Removal

1. Remove one nut and arm and blade assembly.
2. Remove the ten wiper motor access cover screws from outside of the cab and remove cover.
3. Disconnect the wiper motor wires at the multiple connector under the cowl, and pull the connector plug and wiring out through the grommet hold along with the grommet.
4. Remove four bolts retaining the wiper motor and mounting bracket to the body and remove it from the vehicle.
5. Remove one clip and two nuts and remove the motor from the mounting bracket.

Installation

1. Position he motor to the mounting

bracket. Install two nuts and one clip.
2. Position the wiper motor and bracket assembly to the body and install four bolts. Tighten the bolts to a torque of 48-72 in-lbs.
3. Push the motor wiring and connector plug through the grommet hole and connect it to the multiple connector under the cowl.
4. Position the access cover to the front outer side of the cab and secure it with screws.
5. Install the wiper arm and blade assembly.
6. Check the operation of the motor.

F-100 THROUGH F-350

Removal

1. Disconnect the battery ground cable.
2. Remove the radio (if so equipped) as outlined in Part 35-02.
3. Remove the wiper motor bracket attaching bolts (Fig. 10).
4. Disconnect the wiper motor wires. Then, disconnect the wiper arm linkage from the motor shaft (Fig. 9).

Installation

1. Connect the linkage to motor and install motor bracket attaching bolts (Figs. 9 and 10). Tighten bolts to 8-16 ft-lb torque.
2. Connect wiper motor wires.
3. Install radio as outlined in Part 35-02.
4. Connect battery cable and check wiper motor operation.

ECONOLINE

1. Disconnect the battery ground cable.
2. Disconnect the wiper motor wires at the harness multiple connector or stud terminal.
3. Remove the clip that retains the motor drive arm to the linkage mounting arm and pivot shaft assembly (Fig. 9).
4. Remove the wiper motor bracket attaching bolts and remove the motor and bracket from the vehicle. Then, remove the motor from the bracket.
5. Check the new motor to be sure it is in the park position. Then, install the motor on the mounting bracket.
6. Remove the drive arm from the old motor and install it on the new motor in the park position (in the opposite direction from the ground strap).
7. Install the motor and bracket on the dash panel.
8. Connect the linkage mounting arm and pivot shaft assembly to the motor drive arm and install the retaining clip.
9. Connect the motor wires to the harness or stud terminal and the ground cable to the battery. Then check the operation of the wipers.

L-SERIES

Disconnect the battery ground cable.

Remove the wiper arm and blade assemblies from the pivot shafts. Remove the cowl grille and disconnect the linkage drive arm from the motor output arm crankpin by removing the retaining clip. Disconnect the two (push-on) wire connectors from the motor.

From the engine side of the dash panel, remove the three bolts that retain the motor to the dash and remove the motor. If the output arm catches on the dash during removal, rotate the motor body so that the output arm will clear the opening in the dash.

An output shaft seal of moulded rubber is installed on the casting neck below the output arm. A 5/8 inch thick expanded rubber flat seal is used for sealing the motor to the body sheet metal.

If the motor is being replaced, transfer the output arm and moulded rubber shaft seal to the new motor and

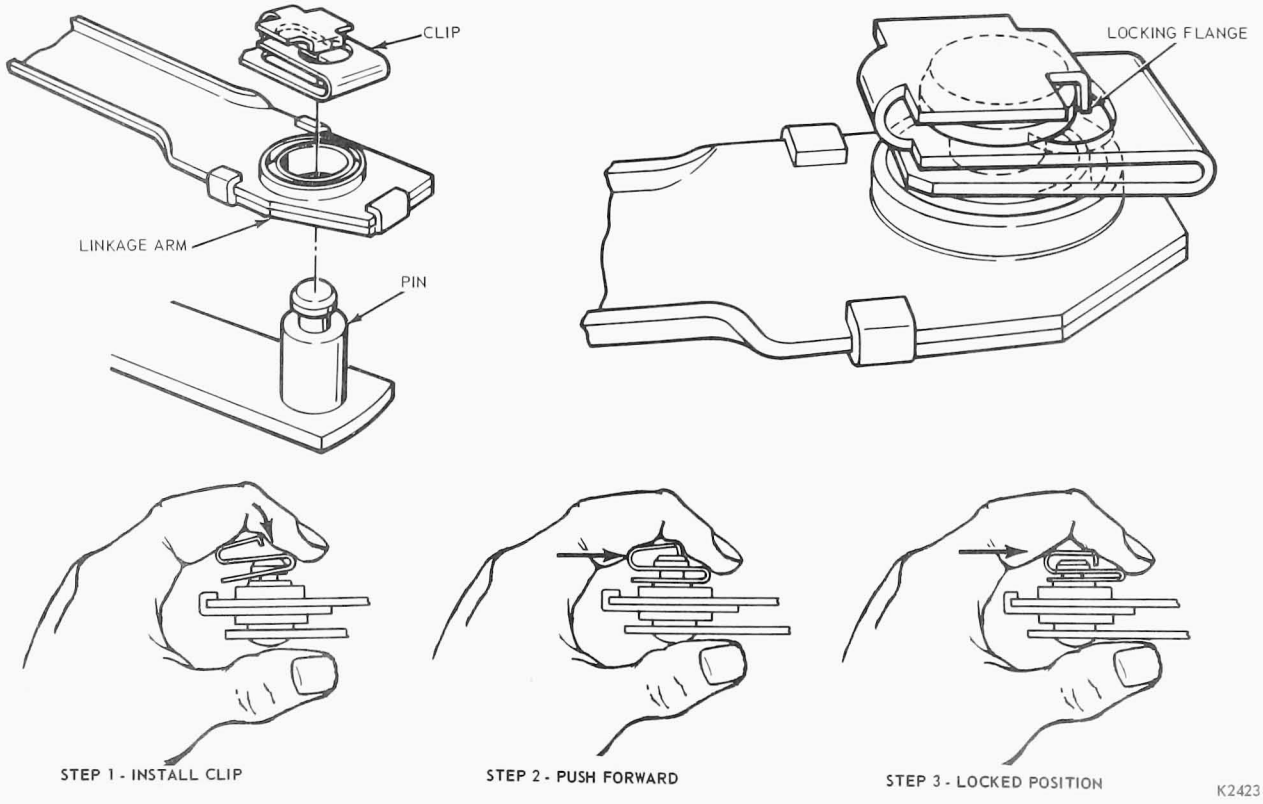

FIG. 9 Wiper Arm Connecting Clip Installation—Bronco, Econoline, F-and L-Series

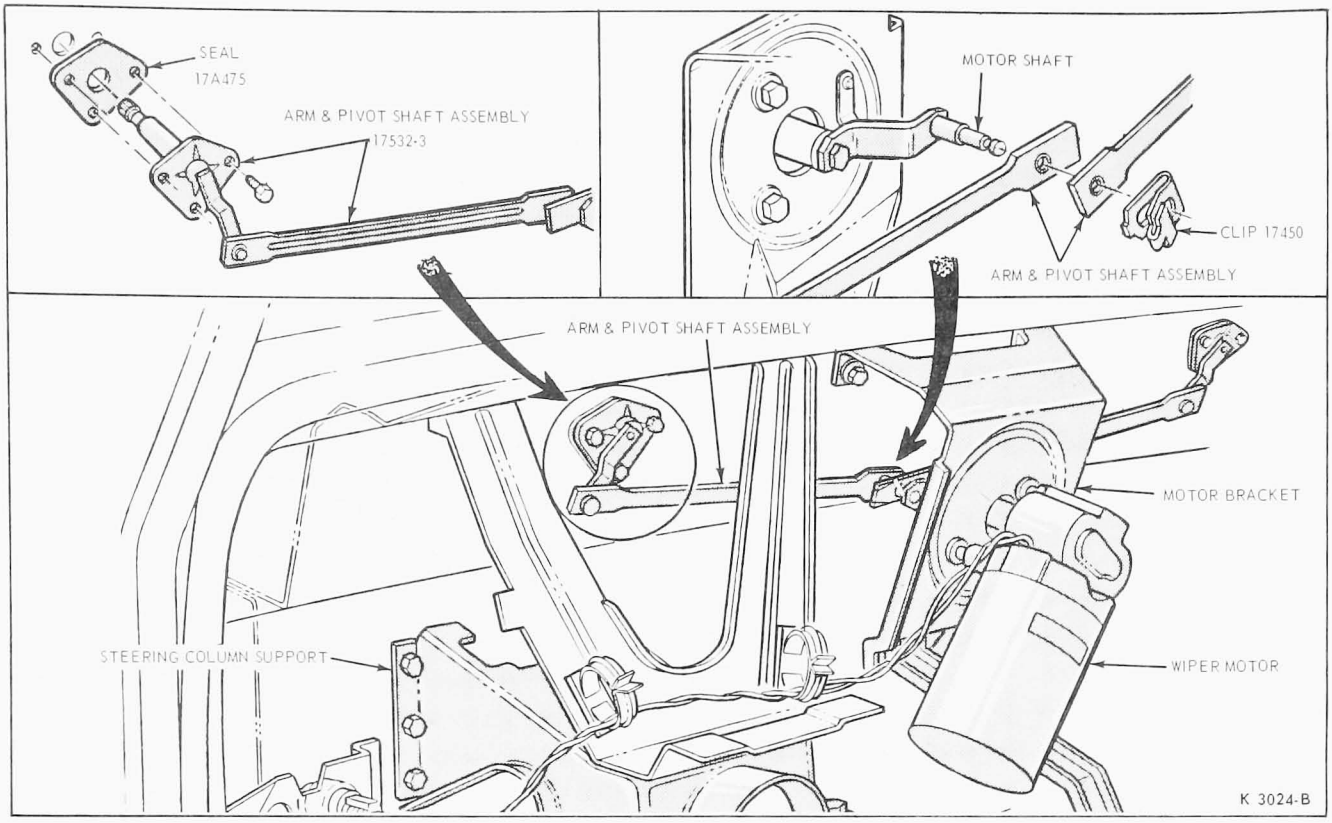

FIG. 10 Windshield Wiper Motor Installation—F-100 Through F-350

then install the flat expanded rubber seal before installing to the body sheet metal.

WIPER CONTROL SWTICH

EXCEPT ECONOLINE

1. Disconnect the battery cable.
2. Remove the wiper switch knob, bezel nut, and bezel.
3. Pull out the switch from under the instrument panel. Disconnect the plug connector from the switch and remove the switch.
4. Position the switch and connect the plug connector.
5. Position the switch in the instrument panel and install the bezel, bezel nut, and knob.
6. Connect the battery cable and check the operation of the switch.

ECONOLINE

1. Disconnect a battery cable at the battery.
2. Loosen the set screw on the wiper control knob, and remove the knob.
3. Remove the wiper control to instrument panel retaining nut, using tool T56L-700A.
4. Remove the wiper control from the instrument panel, and disconnect the wires at the wiper control.
5. Connect the wires to the replacement wiper control.

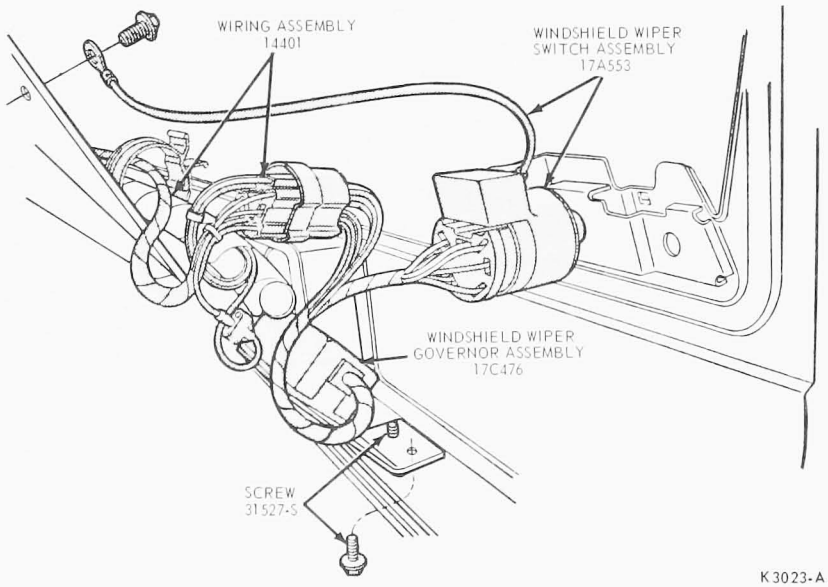

FIG. 11 Windshield Wiper Intermittent Governor

6. Position the wiper control and bezel to the instrument panel and install the retaining nut.
7. Place the control knob on the shaft and tighten the set screw.
8. Connect the battery cable, and check the operation of the wipers.

INTERMITTENT GOVERNOR

F-100 THROUGH F-350

1. Disconnect the wire connectors from the governor.
2. Remove the two governor attaching

screws (Fig. 11), and remove the governor.
3. Position the governor to the instrument panel flange, and install the two attaching screws.
4. Connect the wire connectors, and check the operation of the wiper system.

BLADE ASSEMBLY TO WIPER ARM

Wiper blades are used from two different manufacturers. We will use the first letter of the manufacturers trade name to indicate the type of blade.

T and A blades come in two types. With a bayonet type, the blade saddle slides over the end of the arm and is engaged by a locking stud. With the bottom type, a screw and nut is used to retain the blade on the arm.

BAYONET TYPE

To remove a T type blade, press down on the arm to unlatch the top stud. Depress the tab on the saddle (Fig. 12) and pull the blade from the arm.

To remove an A type blade, press inward on the tab (Fig. 13) and pull the blade from the arm.

To install a new blade assembly, slide the blade saddle over the end of the wiper arm so that the locking stud snaps into place.

RUBBER ELEMENT TO WIPER BLADE

The rubber element in all blades can be replaced.

A-TYPE

To remove, depress the latch pin and slide the element out of the yoke jaws (Fig. 14).

To install, slide the element through the yoke jaws and insert the blade frame assembly into the slots of the yoke jaws.

T-TYPE

To remove, squeeze the latch lock release and pull the element out of the lever jaws (Fig. 14).

To install, insert the new element through each of the lever jaws. Be sure the element is engaged in all of the lever jaws.

If the arm or blade assembly is bent or distorted, replace the complete blade assembly.

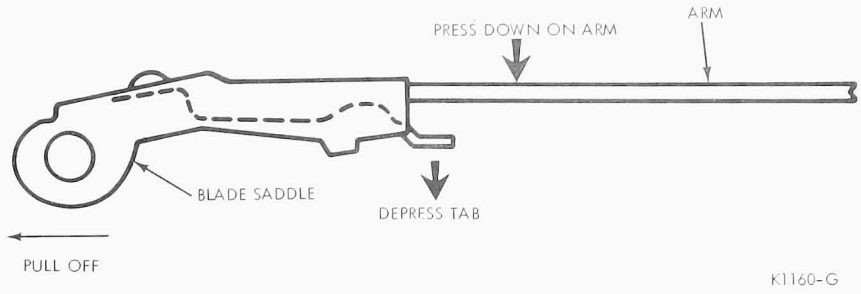

FIG. 12 T Blade—Bayonet Type Removal

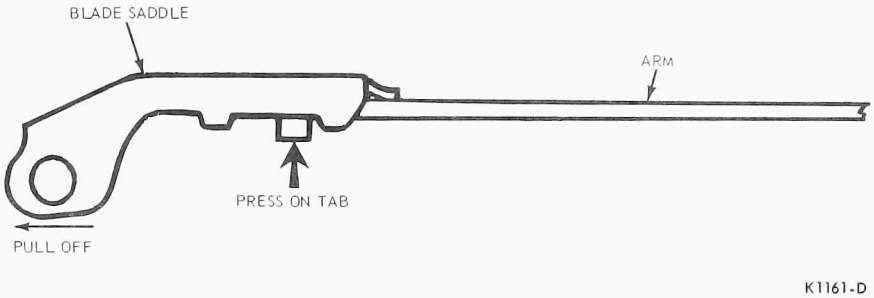

FIG. 13 A Blade—Bayonet Type Removal

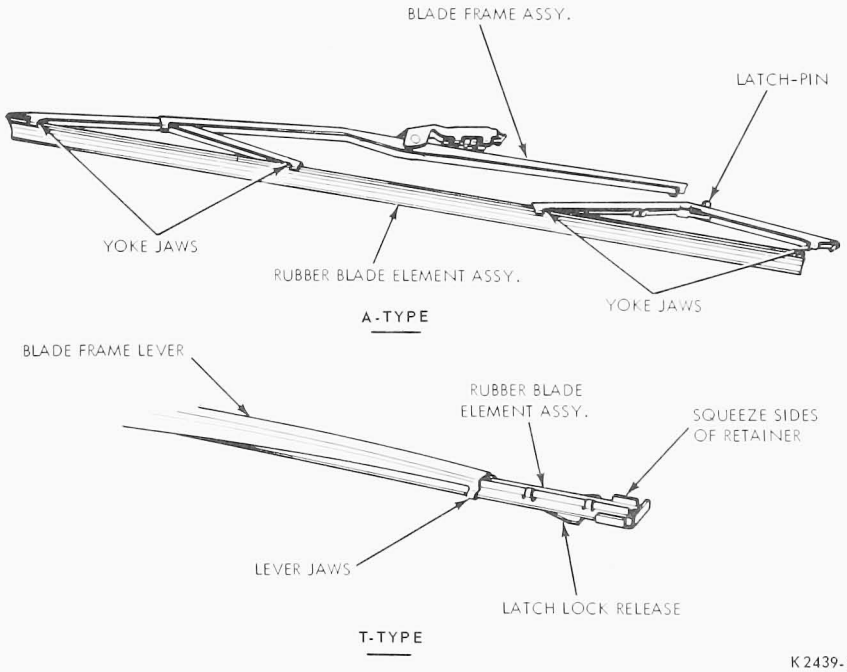

FIG. 14 Rubber Element Replacement

PIVOT SHAFT AND LINKAGE

BRONCO

Remove the windshield wiper arm and blade assemblies from their pivot shafts. Disconnect the linkage arm from the motor drive arm by removing the retaining clip. THE RIGHT AND LEFT PIVOT SHAFT ASSEMBLIES ARE EACH RETAINED TO THE WINDSHIELD HEADER BY TWO MOUNTING SCREWS and OCTAGONAL NUT. Remove these mounting screws and nut, and remove the pivot shafts and linkage as an assembly.

ECONOLINE

1. Remove the wiper blade and arm assembly from the pivot shaft.
2. Working under the instrument panel from inside the vehicle, remove the six screws retaining the pivot shafts.
3. Remove the retaining clip that secures the linkage to the wiper motor arm and remove the linkage and pivot shafts from the vehicle.
4. Position the pivot shafts in the mounting holes on the front cowl panel. Secure the linkage to the motor arm with the retaining clip.
5. Install the six screws retaining the pivot shafts to the cowl.
6. Install the wiper arm and blade assemblies to the pivot shafts and check the operation of the wipers.

F-SERIES

Removal

1. Open the hood and disconnect the battery ground cable. Remove the arm and blade assemblies from the pivot shafts.
2. Reach under the instrument panel and disconnect the speedometer cable from the rear of the instrument cluster.
3. Remove the instrument cluster bezel.
4. Loosen the three bolts retaining the wiper motor bracket to the cowl. This will allow access between the cowl panel and the link assembly.
5. Remove the clip retaining the motor drive arm to the link assemblies (Fig. 9).
6. Through the cluster bezel opening, remove the retaining bolts from the left pivot assembly. Remove the left pivot and link assembly from under the instrument panel.
7. Remove the glove box assembly.
8. Remove the three bolts retaining the right pivot and link assembly to the cowl panel.
9. Disconnect the right link assembly from the drive arm and remove the right pivot and link assembly.

Installation

1. Place gaskets on the pivot shafts and position the shafts to the cowl panel and install the retaining bolts.
2. Install the glove box assembly.
3. Position the link assemblies to the motor drive arm and install the retaining clip (Fig. 9).
4. Tighten the bolts retaining the motor bracket to the cowl.
5. Install the wiper arm and blade assemblies (Fig. 8).
6. Position and install the instrument cluster bezel.
7. Connect the speedometer cable.
8. Connect the battery ground cable and close the hood and check the operation of the wipers.

L-SERIES

Removal

1. Open the hood and disconnect the battery ground cable.
2. Reach under the instrument panel and disconnect the speedometer cable from the rear of the instrument cluster.
3. Remove the instrument cluster.
4. Loosen the three bolts retaining the wiper motor to the mounting bracket. This will allow access between the cowl panel and the link assembly.
5. Remove the clip retaining the motor drive arm to the link assemblies (Fig. 9).
6. At the outer side of the cowl, remove the pivot shaft retaining nut from the left pivot shaft. Remove the left pivot and link assembly through the cluster opening.
7. Remove the glove box assembly.
8. At the outer side of the cowl, remove the pivot shaft retaining nut from the right pivot shaft.
9. Disconnect the link assembly from the drive arm and remove the pivot and link assembly.

Installation

1. Position the right pivot shaft to the cowl panel and install the retaining nut from outside. Tighten the nuts to a torque of 75-100 in-lbs. Slide the right link assembly onto the motor drive arm.
2. Through the cluster opening, position the left pivot shaft to the cowl panel and install the retaining nut from the outside. Tighten the nut to a torque of 75-100 in-lbs. Slide the left link assembly onto the motor drive arm, and install the retaining clip (Fig. 9).
3. Install the glove box assembly.
4. Tighten the bolts retaining the motor bracket to the cowl.
5. Install the wiper arm and blade assemblies.
6. Position and install the instrument cluster assembly.
7. Connect the speedometer cable.
8. Connect the battery ground cable and close the hood and check the operation of the wipers.

DISASSEMBLY AND ASSEMBLY

The wiper motor is not serviced in a complete assembly or in individual parts, but in kits of the major sub-assemblies. Removal and installation procedures are given here for the kits.

COVER AND SWITCH ASSEMBLY

L-SERIES

Remove the four cover retaining screws to remove the assembly. Replace with the appropriate kit. Be sure to reassemble the ground strap under the cover screw. Use the new screws supplied with the kit and tighten to 15-25 in-lbs. torque.

BRUSH END PLATE

L-SERIES

Carefully observe the original position of the bale retainer and pry it off with a screwdriver. Remove the end plate and plug. Replace it with the appropriate kit.

When installing the end plate, use a fine wire probe through the hub opening to position the brushes on the commutator. Rotate end plate to position the key in the notch and assemble the plug. Reinstall the bale retainer carefully with a screwdriver to avoid overbending.

WIPER MOTOR

EXCEPT L-SERIES

Disassembly

1. Remove the gear cover retaining screws, ground terminal and cover (Fig. 15).
2. Remove the idler gear by pressing shaft with retainer out of the motor housing.
3. Remove the motor through bolts, motor round case, switch terminal insulator sleeve, and armature. Do not pound the motor case magnet assembly as the ceramic magnets may be damaged.
4. Mark the position of the output arm with respect to the output shaft for assembly. Remove the output arm retaining nut, output arm, wave washer, flat washer, O-ring, leaf spring, output gear/shaft assembly, and parking switch lever and parking switch lever plate.
5. Remove the brushes, bush springs, and wire harness.
6. Remove the brush plate and switch assembly, and remove the switch contact to parking lever pin from the gear housing.

Assembly

It is essential that the idler gear shaft with the push-nut be reset to the original, proper depth in the gear housing.

1. Place the housing on a flat surface with the inside of the housing facing up.
2. Position the parking switch lever and lever plate with the cam rider pointing toward the gear housing output shaft hole.
3. Apply a film of Sun Prestige grease to the output gear teeth and shaft bearing surface. Insert the shaft in the bearing. Make certain that the parking switch lever is clear of the cam and gear assembly.
4. After installing idler gear on shaft insert shaft through park lever and plate. Use a drift and hammer to lightly tap the gear and pinion shaft to proper dept. (Do not allow push-nut to put a pre-load on gear. A .001-.007 in clearance is required.)
5. Position the brush springs and brushes in the holders and wrap wire around them to hold them in the fully retracted position. Push the insulated brush connector into the switch terminal.
6. Place the switch contact to parking lever pin in the gear housing. Position the brush plate assembly to the housing and install the retaining screws.
7. Apply Sun Prestige grease to the ball bearing in the end of the armature shaft. Position the armature shaft in the gear housing and remove the brush retracting wires.
8. Holding the armature in position, install the motor case and magnet assembly, and through bolts. Align indicator marks on motor case and gear box housing before inserting through bolts.
9. Apply Sun Prestige grease to the worm gear and pinion and idle gear. Install end play spring in housing.
10. Apply a generous amount of Sun Prestige grease to the area around the end of the armature shaft. Install the gear housing cover.

Cleaning and Inspection

1. Clean the gear housing of all old grease. Do not allow any cleaning fluid to contact the armature shaft and output shaft bearings.
2. Wipe all other parts with a clean cloth.
3. Inspect the gear housing for cracks or distortion. Replace a cracked or distorted housing.
4. Check all shafts, bushings, and gears for scored surfaces. Replace damaged parts, and add new grease to the housing and gears.

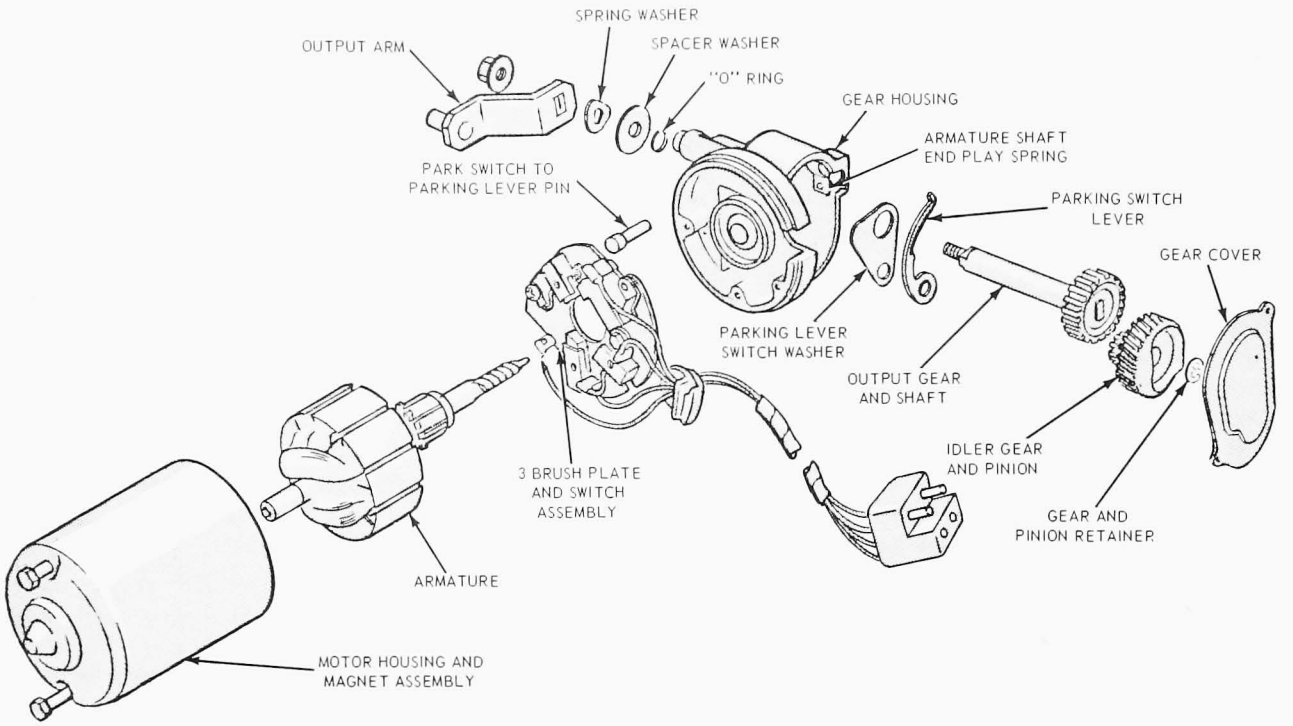

FIG. 15 Disassembled Wiper Motor

PART 35-63 Windshield Wipers—Air

REMOVAL AND INSTALLATION

WIPER MOTOR

L-SERIES

Removal

1. Open two air tank pet cocks to allow air pressure in the system to exhaust.
2. Disconnect two plastic air lines from the wiper motor.
3. Remove the clip retaining two pivot shaft links to the wiper motor.
4. Remove the two nuts retaining the wiper motor to the mounting bracket (Fig. 1).
5. Transfer the fittings.

Installation

1. Position the motor to the mounting bracket. Install the two retaining nuts.
2. Position the arms to the motor and install the retaining clip.
3. Connect two nylon air lines to the motor.
4. Close the two air tank pet cocks.
5. Start the engine and check the wiper operation.

C-SERIES

Removal

1. Exhaust the air pressure from the air system.
2. Remove the wiper motor access cover.
3. Disconnect the air line from the wiper motor (Fig. 2).
4. Disconnect the wiper drive linkage and wiper motor control cable from the motor (Fig. 2).
5. Remove the wiper motor attaching screws and remove the wiper motor.

Installation

1. Position the wiper motor to the vehicle and install the attaching screws.
2. Connect the wiper drive linkage and the air line to the wiper motor (Fig. 2).
3. Connect the wiper motor control cable to the motor.
4. Move the motor drive lever to the extreme position as shown by arrow A in Fig. 2. Keep the drive lever in that position. Then, force the cable housing in the direction of arrow B (Fig. 2) until a positive stop is felt.
5. Release the cable housing but continue to hold the drive lever in the direction of arrow A. Then, tighten the cable housing retaining screw.
6. Check the operation of the wiper motor. If the motor continues to operate when the control is in the OFF position, back-off the control screw (Fig. 2) until the condition is corrected.
7. Install the wiper motor access cover.

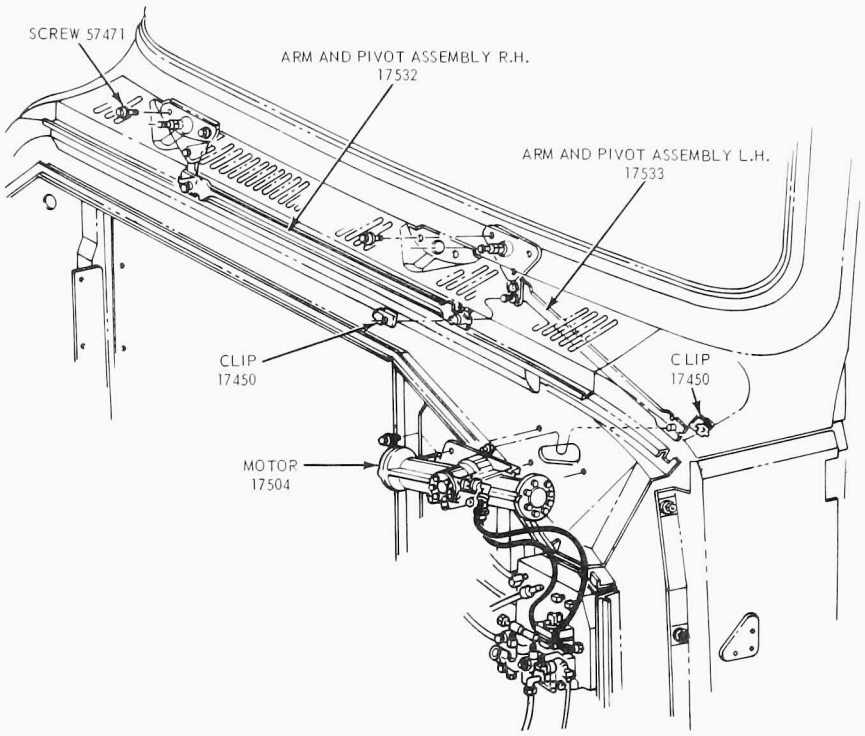

FIG. 1 Air Wiper—L and C-Series

W-SERIES

Removal

1. Open the air tank pet cocks to allow air pressure in the system to exhaust it.
2. Remove the arm and blade assembly retained by a nut and washer.
3. Remove the adapter with the use of a puller.
4. Remove the rubber boot, nut and washer.
5. Remove the cover from the front outside of the cab secured by four screws (Fig. 3).
6. Remove two mounting bolts and disconnect three rubber vacuum lines and remove the motor.
7. Transfer the mounting bracket.
8. Transfer the two fittings.

Installation

1. Connect the three vacuum hoses. Position the motor and bracket assembly to the cab and install the two bolts.
2. Install the cover plate with four screws.
3. Install the washer nut and rubber boot to the shaft.
4. Tap the adapter on the shaft.
5. Install the wiper arm, blade, washer and nut.

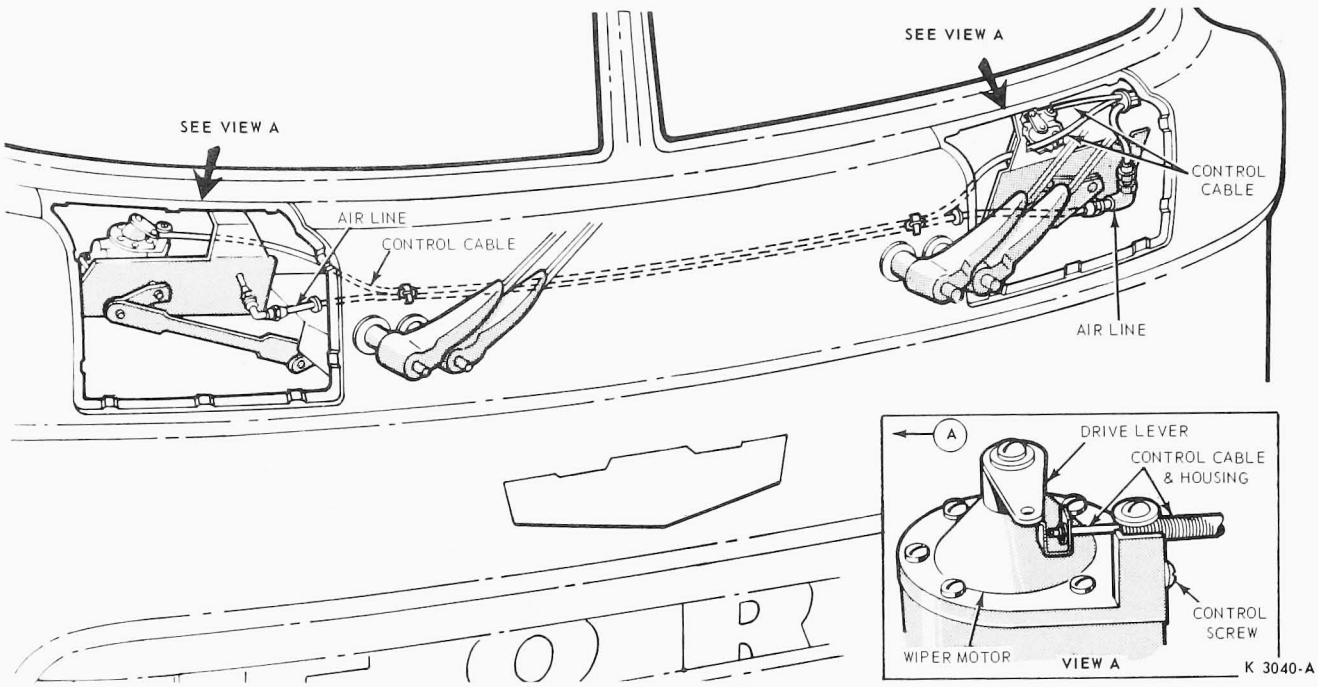

FIG. 2 Air Wipers—C-Series

6. Close the air tank pet cocks.
7. Start the engine and check the wiper operation.

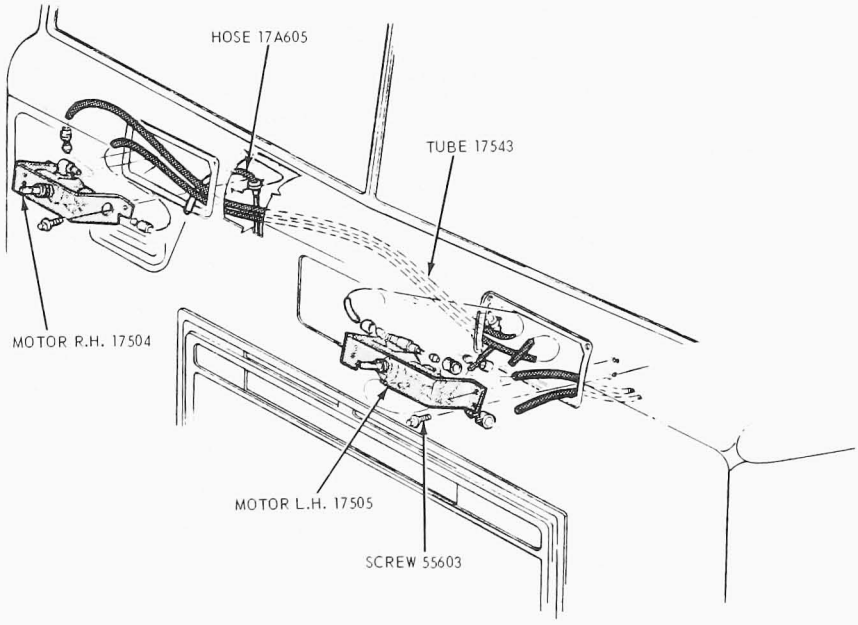

FIG. 3 Air Wiper W-Series

PART 35-70 Windshield Washers

DESCRIPTION AND OPERATION

WASHER SYSTEM—ELECTRIC

The electric windshield washer system consists of an instrument panel control switch, integral with the wiper control switch, reservoir and motor assembly and the necessary hoses, nozzles and attaching parts.

WASHER SYSTEM—MANUAL

The manual windshield washer system consists of a foot operated pump, reservoir and the necessary hoses, nozzles and attaching parts.

TESTING

WASHER PUMP CURRENT DRAW TEST

Attach the leads of the Volt-Amp Tester as shown in Fig. 1. The current draw should not exceed four amps while the washer pump is pumping fluid.

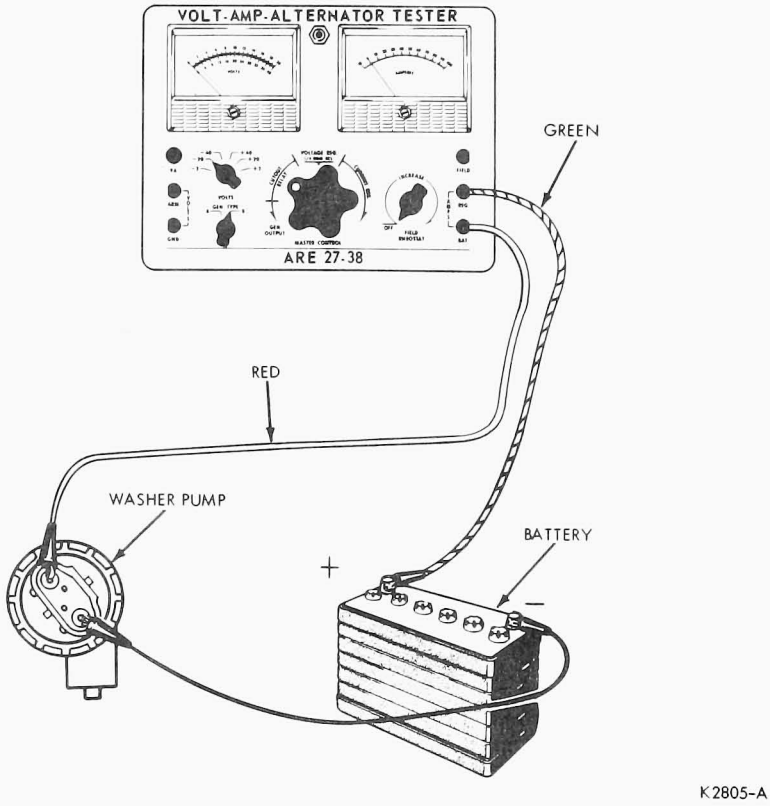

FIG. 1 Washer Pump Current Draw Test

ADJUSTMENTS

WASHER NOZZLE

F-SERIES

The adjustment of either washer nozzle can be accomplished by bending the nozzle tube to provide desired windshield washer fluid distribution.

C-SERIES

Use a 0.015 inch diameter pin to adjust both nozzles on each washer jet.

L-SERIES

Rotate adjusting screw with Phillips screw driver to obtain the desired spray pattern.

ECONOLINE AND W-SERIES

Carefully turn the nozzle with a blade screwdriver to obtain the desired spray pattern.

BRONCO

The Bronco windshield washer nozzles are not adjustable.

WASHER PUMP—ELECTRIC

To remove the electric windshield washer reservoir and motor assembly from the vehicle, disconnect the lock-tab wire connector (use a small screwdriver to unlock the tabs) and hose. Remove the retaining screws and lift the assembly from the left fender apron (or radiator support). Disconnection of the hose will drain the reservoir. The washer reservoir and motor assembly is serviced separately as is the cover and screen assembly. The motor, motor retainer and seal and pump impeller are not serviced separately.

The cover and reservoir are assembled with an interference fit. To remove the cover, grip the reservoir and tug on the cover strap until the cover comes off. To assemble the cover and reservoir, snap together by hand.

Attach the reservoir and motor assembly to the vehicle with the retaining screws. Connect the lock-tab wire connector and hose. Fill the reservoir and operate the washer system. Check for leaks and align the nozzles if necessary.

Do not operate the pump before adding fluid to reservoir.

WASHER PUMP—MANUAL

Pull back the floor covering and disconnect the hose from the pump (Fig. 2). Then, remove the two pump attaching screws and remove the pump.

To install, position the pump and install the two attaching screws. Then, connect the hose to the pump.

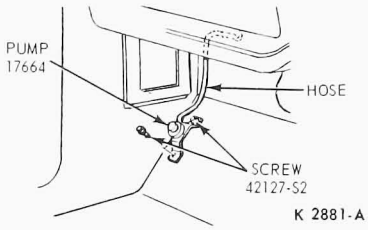

FIG. 2 Washer Pump—Foot Operated

PART 35-80 Horns

DESCRIPTION AND OPERATION

ALL EXCEPT BRONCO

All trucks are equipped with a single horn controlled by a relay. Dual horns are also available. The horn button closes the relay contacts, completing the circuit to the horn(s).

BRONCO

Bronco has a single horn that does not require a relay in the circuit. The horn button closes the circuit directly to the horn.

The circuit for the Econoline single horn or dual horns is controlled by a relay. The horn button circuit closes the relay contacts, completing the horn circuit.

TESTING

The only test necessary on a horn is for current draw.

Connect a voltmeter and ammeter to the horn and to a voltage supply as shown in Fig. 1. The normal current draw for the horns at 12 volts is 4.0 to 5.0 amperes.

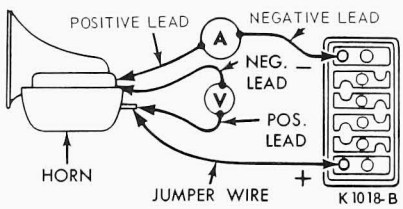

FIG. 1 Horn Current Draw Test

ADJUSTMENTS

The current is adjusted by changing the contact tension. Connect the horn as shown in Fig. 1. Turn the self-locking adjusting screw until the current is within the limits for the horn being adjusted.

REMOVAL AND INSTALLATION

HORN

ALL EXCEPT BRONCO AND ECONOLINE

The horns are mounted on the right and left radiator support. Tilt cab horns are mounted inside the cab hinge bracket. On Parcel Delivery trucks, the horn is mounted on the front of the dash board.

Disconnect the horn wire at the terminal, remove the retaining screws, and remove the horn.

To install, place the horn in position, and install the retaining screws. Install the horn wire.

BRONCO

Disconnect the horn wire at the terminal and remove the bolt and nut

retaining the horn to the left fender apron at the grille. Then, remove the horn.

Install the horn and secure it with a bolt and nut. Connect the lead. Check the horn operation.

ECONOLINE

Econoline horns are mounted on the forward face of the dash panel, high on the left side of the vehicle, and are accessible by raising the hood. To remove a horn, disconnect the wire connector at the horn terminal and remove the screw and lock washer retaining the horn assembly to the dash panel. To install, secure the horn in position with the screw and lock washer and connect the wire connector. Close the hood and check the operation of the horn.

HORN BUTTON

EXCEPT F-100 THROUGH F-350

The horn button assembly can be removed by pressing down evenly and turning the button counterclockwise until it lifts out. It is advisable to disconnect the connector at the horn relay (Battery on Bronco) to prevent the horns from sounding during this operation.

HORN BUTTON AND BRUSH PLATE W-SERIES

Removal

1. Disconnect the wire connector under the turn signal switch.
2. Press down evenly on the horn button and turn counterclockwise until it lifts out of the steering wheel hub. Remove the horn button spring.
3. Mark the steering wheel position on the steering column. Then, remove the steering wheel retaining nut and remove the steering wheel.
4. Remove the two screws that retain the plate and bush assembly to the steering column hub (Fig. 2). Then, unplug the wire connector from the plate and bush assembly and lift from steering column.

Installation

1. Place the plate and bush assembly to the steering column hub and connect the wire connector to the assembly. Install the two attaching screws.
2. Install the steering wheel and retaining nut. Refer to Group 13 for the nut torque specification.
3. Install the horn button spring and button.
4. Connect the wires at the connectors under the turn signal switch.

HORN SWITCH

ALL EXCEPT F-100 THROUGH F-350 AND W-SERIES

The horn switch is an integral part of the turn signal switch except with I.C.C. Turn Signal Switch (Fig. 2). For access to this switch, follow the procedure given for servicing the turn signal switch in Group 32 of this manual.

HORN SWITCH

F-100 through F-350

1. Remove one screw from the underside of each steering wheel spoke, and lift the horn switch assembly (steering wheel pad) from the steering wheel.
2. Disconnect the horn switch wires by pulling the spade terminal from the blade connector (Fig. 2). Squeeze or pinch the ground wire terminal firmly and pull it out of the hole in the steering wheel. **Do not pull the ground terminal out of the threaded hole without squeezing the terminal** to relieve the spring retention of the terminal in the threaded hole.
3. To install, connect the spade terminal to the blade connector, and press the ground terminal fully into the threaded hole (Fig. 2).
4. Position the horn switch (pad) on the steering wheel, and install the two attaching screws.

HORN RELAY

EXCEPT BRONCO AND ECONOLINE

Remove the wire connector from the horn relay. Remove the retaining screws and remove the relay.

ECONOLINE

The Econoline horn relay is located on the lower edge of the instrument panel, just to the right of the headlight switch. To replace the relay, disconnect the wire connector and remove the retaining screw. Attach the new relay to the instrument panel with the retaining screw and connect the wire connector. Test the operation of the horns.

REMOVAL AND INSTALLATION Cool Air Ventilator		N/A	N/A	N/A	N/A	02-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

DESCRIPTION

F-AND L-SERIES

The ventilation system consists of two air inlets which, when open, allow fresh air to enter the truck cab. One inlet is located in the left side cowl. The right inlet is located in the right side cowl or is integral with the heater, depending on vehicle and heater applications.

C-SERIES

The tilt cab truck has a fresh air inlet in the front of the truck at the cab floor level. Tilt cabs with a sleeper compartment have a fresh air inlet at the forward edge of the compartment on each side. This inlet is open at all times and cannot be closed. In addition, a hand operated vent on each side of the sleeper compartment can be adjusted to either force air into the compartment or vent it out of the compartment.

W-SERIES

The highway tractor has a hand operated adjustable fresh air inlet

located in each door, and a hand operated vent is located in the roof. In cab sleeper compartments, two-way intake and exhaust vents are offered in both compartments.

ECONOLINE

The left fresh air duct is located on the dash panel at the left side. Slide the door downward to open for fresh air.

The fresh air heater is designed to operate in conjunction with the right side fresh air ventilating system.

A fresh air outlet in the lower part of the heater plenum provides fresh air for the passenger. Rotate the door downward for fresh air. **The right side fresh air outlet must be closed for heating.**

BRONCO

The left fresh air duct is located on the extreme left side of the dash. Fresh air can be obtained through this duct by a manually operated door.

ADJUSTMENTS

VENTILATION CONTROLS-BOWDEN CABLE TYPE

Bowden cable operated vents and air inlets are adjusted so that the vents are tightly closed when the control knobs are all the way in. Loosen the Bowden cable retaining screw at the vent control arm, move the cable housing back and forth until the vent is closed when the knob is 1/16-1/8 inch from the in position, then tighten the retaining screw.

REMOVAL AND INSTALLATION

COOL AIR VENTILATOR—BRONCO

REMOVAL

1. Unlatch and raise the hood. Secure the hood in its open position with the hood support rod.
2. Carefully break the adhesive that secures the vent seal (Fig. 1) to the topside of the cowl. Remove the seal from the cowl.
3. Using force, gently unsnap the drain tube elbow from the duct assembly. Remove the elbow.
4. With the aid of a helper working inside the vehicle and holding the duct assembly in position, remove the ten screws that secure the duct assembly to the rear side of the cowl. Then, remove the eight screws that secure the top of the duct assembly to the top underside of the cowl.
5. Remove the vent assembly from the underside of the cowl.

INSTALLATION

1. Apply adhesive to the duct assembly flange opening.
2. With the aid of a helper holding the duct assembly in position on the underside of the cowl, install the 18 screws securing the vent assembly to the cowl.
3. Position the drain tube elbow at the drain opening and snap it into lock position.
4. Install the adhesive around the top flange of the cowl at the vent seal opening. Place the vent seal in position on the cowl and press down tightly on the mating surface.
5. Disengage the hood support rod from the hood and close the hood.

GENERAL INFORMATION

HEATING SYSTEMS AND CONTROL DOORS

With all Ford heating systems, outside air comes through an opening at the upper cowl and into the right duct of the heater assembly. All heater assemblies contain a heater core, through which flows hot coolant from the engine, and a blower. The air (forced by blower or ram effect) passes through and/or around the heater core and discharges through various outlets.

Several valves or doors determine the amount of air that goes through the heater core and the particular outlet(s) through which it discharges. The number of doors used differ according to the particular vehicle model.

SAFETY PRECAUTIONS

Whenever components in the engine compartment or instrument panel areas are being serviced, the battery ground cable must be disconnected to eliminate the possibility of electrical shorts, burned-up wiring, and dangerous fires. Extreme care must be exercised when performing electrical tests where the battery must be connected to operate the system.

Carbon monoxide is colorless, odorless and dangerous. If it is necessary to operate the engine with the vehicle in a closed area such as a garage, always use an exhaust collector to vent the exhaust gasses outside the closed area.

TESTING

The following tests may be made on the heater: Burned out fuses, loose wire connections, damaged wires, or collapsed hoses. Loose defroster ducts and air leaks in the body may be determined by visual inspection of the parts.

HEATER BLOWER MOTOR CURRENT DRAW TEST

This test will determine if the blower motor is operating properly. Connect a 0-50 ammeter as shown in Fig. 1. The blower motor will operate independently of the control switch, and the current drawn by the motor will be indicated on the ammeter. Current draw should be to specification.

LOOSE BLOWER TEST

Turn on the heater switch, and listen for the sound of the motor. If only a hum is heard, the blower wheel may be loose on the motor shaft.

BLOWER SWITCH TEST

To check the blower switch, place the switch in the off position. Then using a self-powered test light or ohmmeter, check for continuity between all of the terminals, two at a time. If the light should go on, this will indicate a short between the terminals or an inoperative switch.

OPEN CIRCUIT TEST

All electrical circuits must be complete from the source of power (battery), to the unit where the power is used, and back to the source of power again. A check at each connection in a circuit, starting at the battery, will locate an open circuit or will show that the circuit is complete.

An ohmmeter or self-powered test light connected at any two points of a circuit with the power removed from the circuit, will show if the circuit between the two connections is open or complete.

If the meter does not move or has a light movement (high resistance), the circuit may have a poor connection or broken wire. If the bulb does not light, the circuit is open.

If the meter movement is great or full (low resistance), the circuit is

complete. If the bulb lights, the circuit is complete.

PLUGGED HEATER CORE TEST

Start the engine and temporarily remove the outlet hose from the heater core (the hose that leads to the water pump). Very little or no flow of coolant from one core outlet indicates that the core is plugged. Make certain that water is being supplied to the core inlet.

BLEEDING AIR FROM HEATER CORE

Remove the hose at the outlet connection of the heater core (hose that leads to the water pump). Allow any trapped air to flow out. When a continuous flow of coolant is obtained, connect the hose to the core.

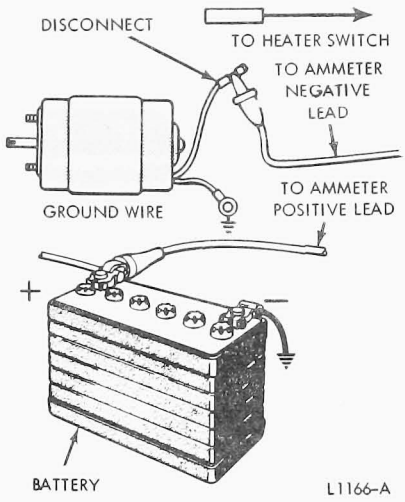

FIG. 1 Heater Motor Current Draw Test

REMOVAL AND INSTALLATION

HEATER HOSE ALL MODELS

To replace a heater hose, drain the coolant, remove the hose, cut a new hose to the same length as the old hose, install the hose, and replace the coolant. Make certain that the heater hose connections to the block are installed correctly. Also that the heater hoses cannot come in contact with any part of the exhaust system, or cannot become pinched in the tilt cab mechanism.

After the coolant has been replaced, bleed the air from the heater core.

DESCRIPTION AND OPERATION

Fresh air and recirculating heaters are available for various truck models, depending on model and engine usage. An auxiliary fresh air heater is available on trucks equipped with a sleeper cab.

FRESH AIR HEATER

F-100 THROUGH F-350

The heater used in the light truck is a fresh air heater drawing air from the cowl top area. The heater is mounted to the dash panel on the right side under the instrument panel (Fig. 1). The fresh air source for the heater is the right fresh air vent which is attached to the heater and the cowl side panel.

An air door within the heater controls the flow of air through the heater. This air door is controlled by the mode (lower) control lever. When the mode lever is in the OFF position, all air through the heater is shut off (ram air included). All air is directed to the floor area when the mode lever is in the FLOOR position, and to the windshield when the lever is in the DEF position. Air is directed to both the floor and windshield when the mode lever is positioned between FLOOR and DEF.

The temperature of the discharged air is controlled by the temperature (upper) control lever. Maximum cool air (fresh outside air) can be obtained by moving the temperature lever to the far left, and maximum heat when the temperature lever is at the far right. The temperature of the air can be varied by moving the lever to any position desired between COOL and WARM.

The blower switch has four positions; OFF, two intermediate positions, and HIGH. Ram air can be obtained when the vehicle is in forward motion and the mode lever is in any position other than OFF.

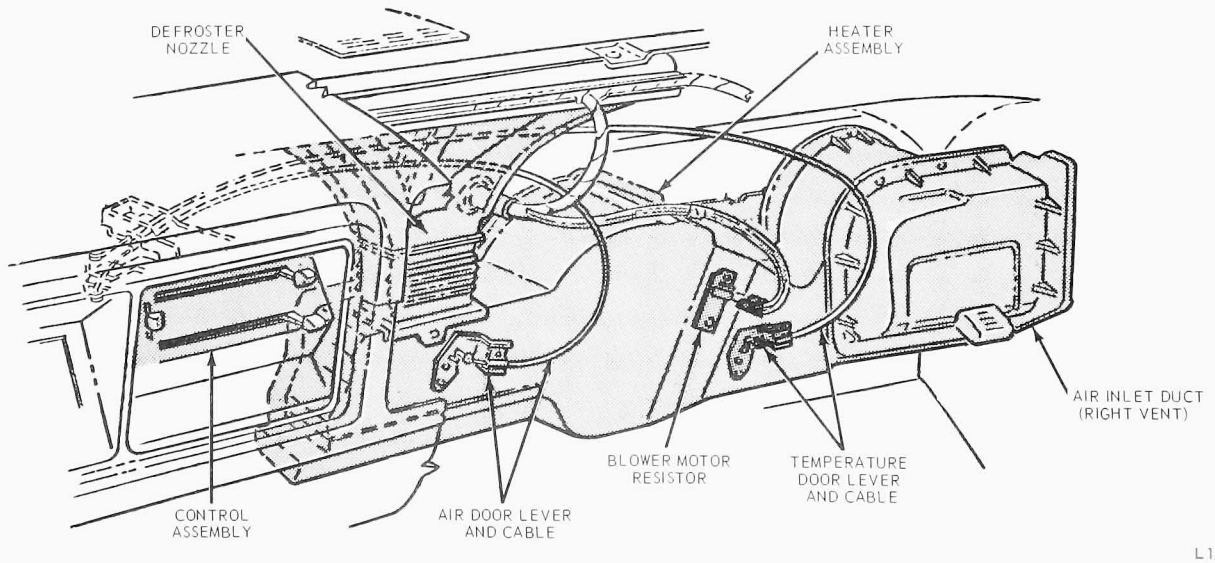

FIG. 1 Fresh Air Heater—F-100 Through F-350

FRESH AIR HEATER—F-500 THROUGH 750 AND L—SERIES

The fresh air heater is mounted to the dash panel and is connected to the right side cowl air duct (Figs. 2 and 3). This allows the heater to draw fresh air from outside the cab for heating and defrosting. An air door within the heater housing controls the air flow through the heater. This air door is controlled by sliding the heat lever to the heat position (F-500 through F-750) or by pulling the heat knob out (L-Series).

The temperature of the heated air is controlled by a valve that regulates the flow of water from the engine to the heater. The valve is operated by the **TEMPERATURE** control on the heater control panel. When no heat is desired, the temperature control is moved to the **OFF** position (F-500 through F-750) or the knob is pushed all the way in (L-Series). This closes the water control valve and stops the circulation of water through the heater core.

The defroster control operates an air door in the heater plenum chamber. On economy fresh air heater, a manual control located on the plenum regulates the defrost and heat doors.

Two speeds are provided for the heater blower by means of a three-position switch and a resistor.

FRESH AIR HEATER

C-SERIES

The fresh air heater is mounted to the dash panel under the instrument panel (Fig. 4), and draws fresh air from outside the cab and/or recirculated air from inside the cab for heating and defrosting. A shutter on the heater housing, draws fresh air from behind the truck grille when the fresh air control is pulled out.

The temperature of the heated air is controlled by the fresh air control. For maximum heat, push the fresh air knob all-the-way in. Pull the control knob out for minimum heat. Any position between full in and full out will result in air temperatures between maximum and minimum heat. Air flow is controlled by the heater blower switch. (center control)

Defroster operation is controlled by the defrost switch which operates the defroster blower motor. This is a separate blower motor from the heater blower.

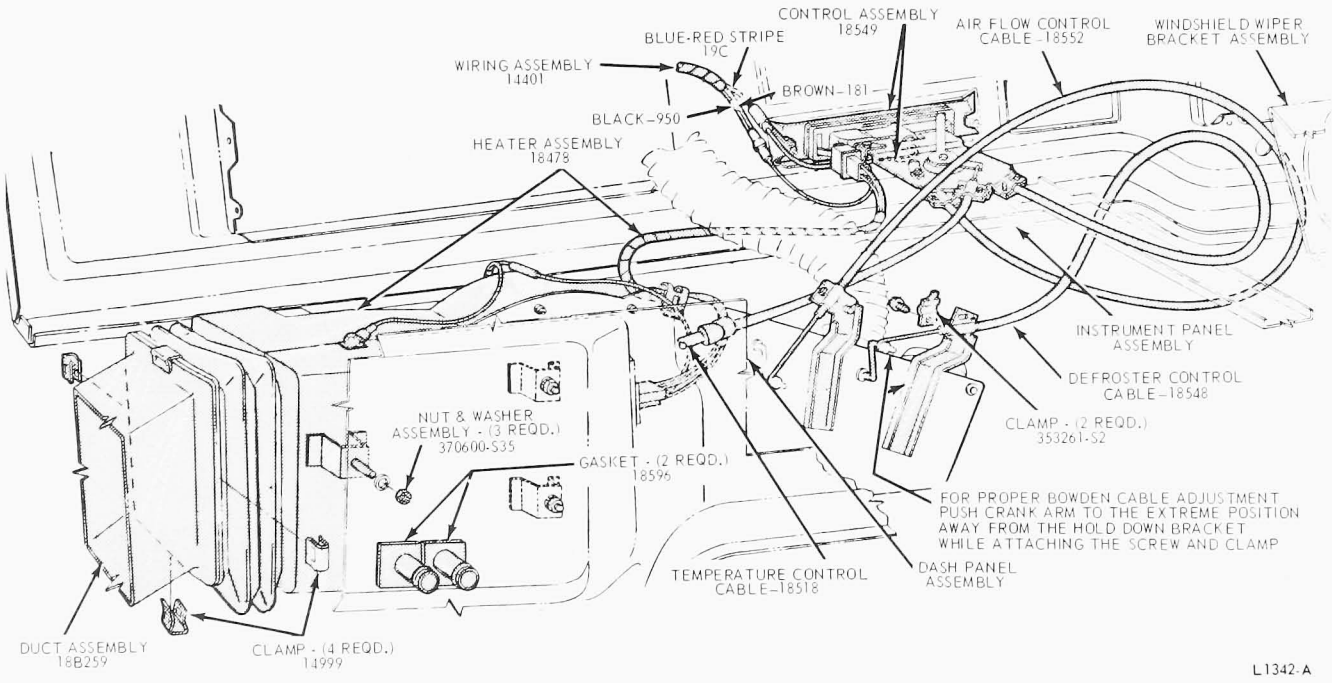

FIG. 2 Heater Installation—F-500 through F-750

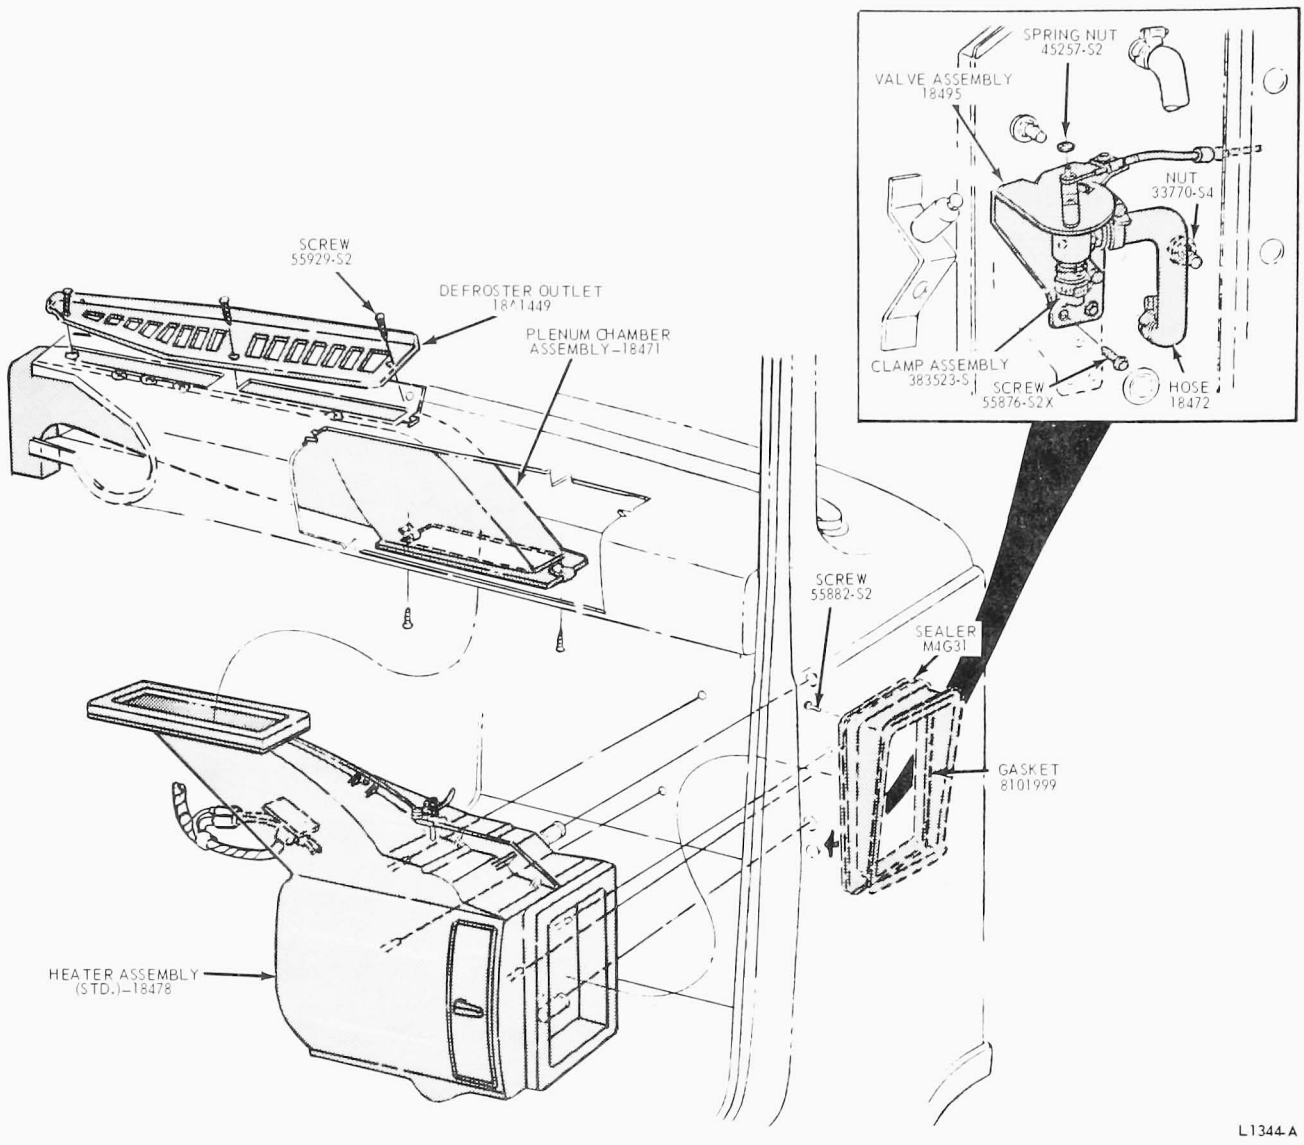

FIG. 3 Heater Installation—L-Series

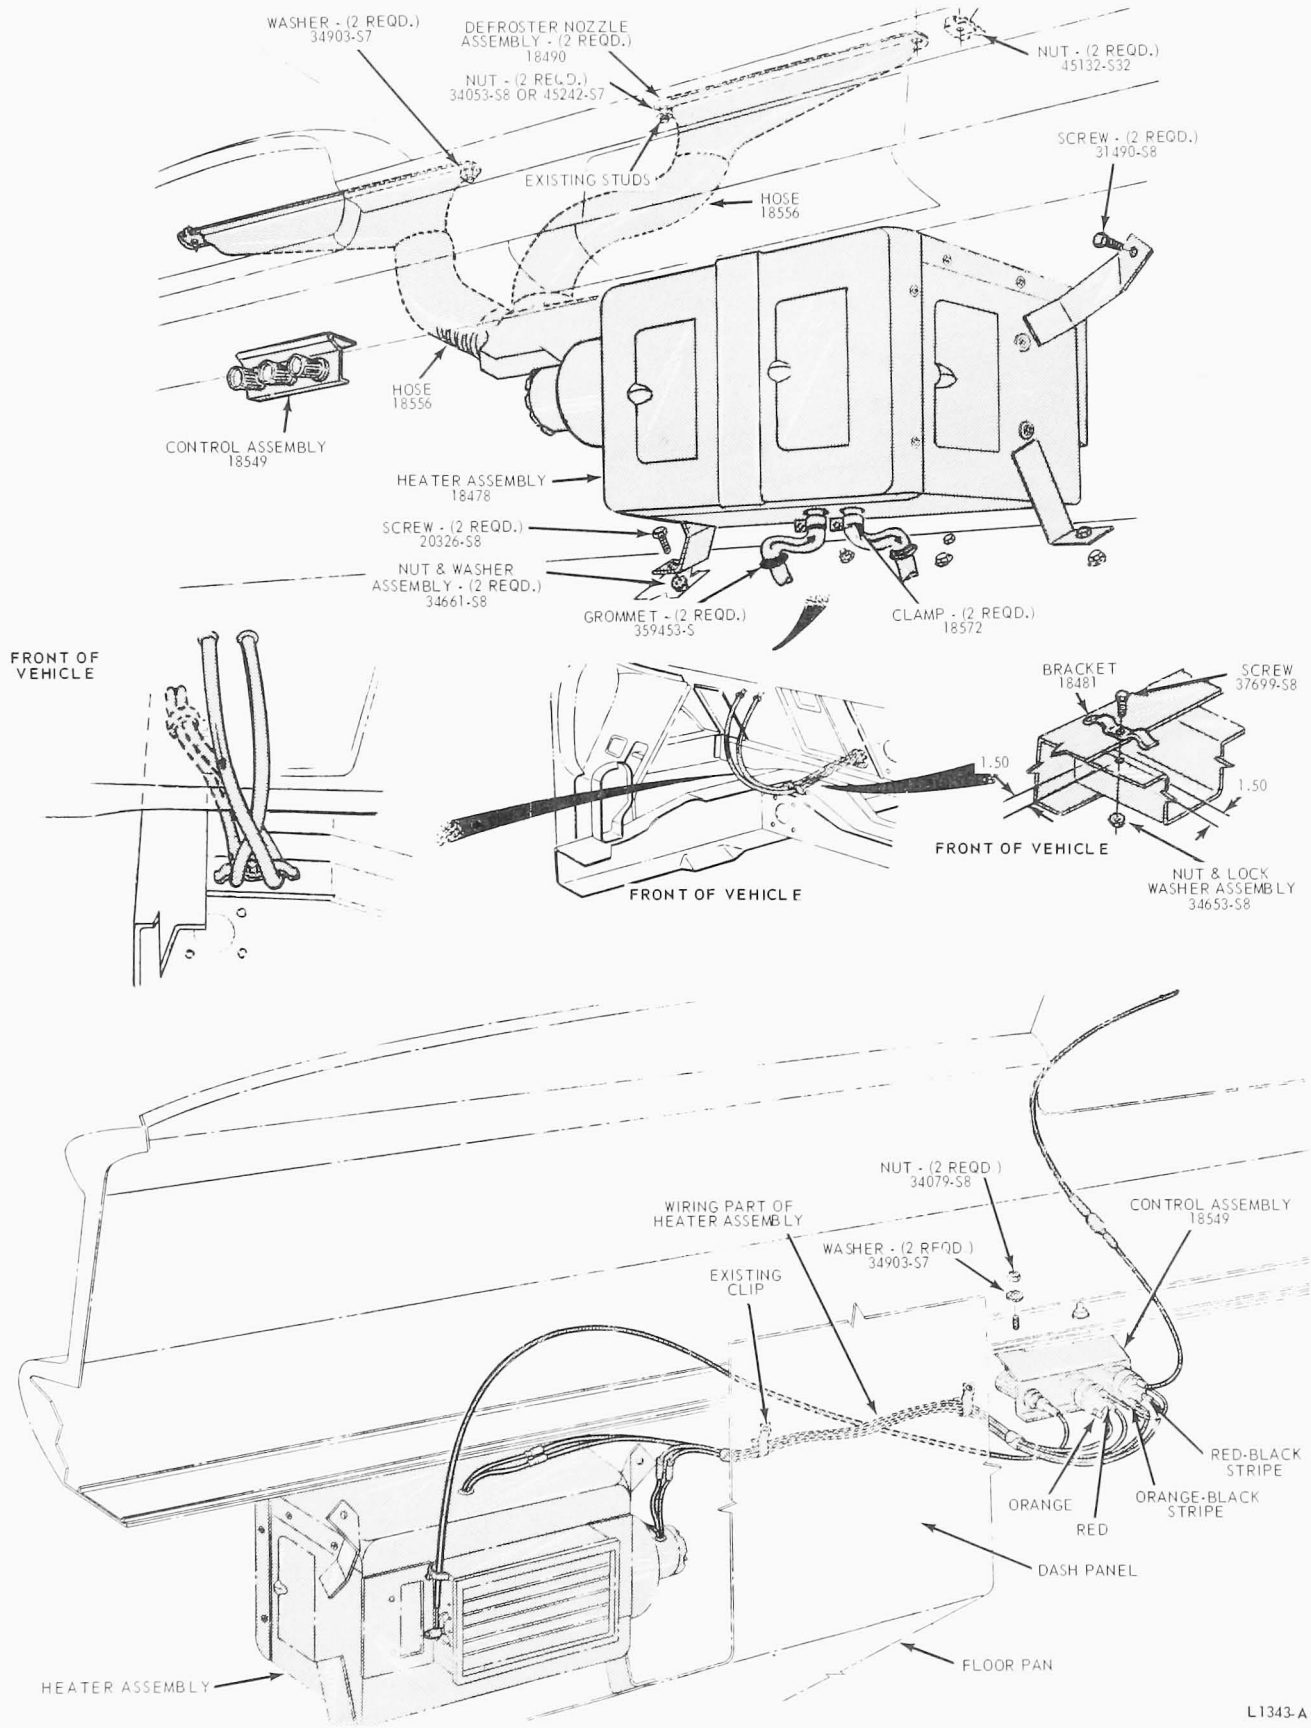

FIG. 4 C-Series Heater

ADJUSTMENTS

CONTROL CABLES

F-100 THROUGH F-350

Air Door Control Cable

To adjust the mode control cable, loosen the cable clamp screw at the plenum. Place the mode (lower) control lever in the DEF position. Then, push the air door crank to the extreme right position (Fig. 5), and tighten the cable clamp attaching screw.

Temperature Control Cable

To adjust the temperature control cable, loosen the cable clamp at the heater housing. Place the temperature (upper) control lever in the WARM position. Then, push the temperature door crank to the extreme right position (Fig. 5), and tighten the cable clamp attaching screw.

F-500 THROUGH F-750

Heat Door Control Cable

1. Loosen the cable clamp at the heater housing (Fig. 2).
2. Move the lower control lever to the mid-position of the control head slot.
3. Pull the heat door crank arm to full open position (towards driver's side) and tighten the cable retaining clamp.

Defrost Door Control Cable

1. Loosen the cable clamp at the heater housing (Fig. 2).
2. Move the lower control lever to the mid-position of the control head slot.
3. Pull the defrost door to off position (towards driver's side) and tighten the cable retaining clamp.

Temperature (Water Valve) Control Cable

1. Loosen the cable clamp at the heater water valve.
2. Move the upper control lever to off position.
3. Pull the water valve crank arm to the off position (toward front of vehicle) and tighten the retaining clamp.

Removal and Installation

HEATER ASSEMBLY

F-100 THROUGH F-350

Removal of the heater assembly is necessary for blower motor and/or heating core replacement.

Removal

1. Disconnect the temperature and air door Bowden cables from the heater housing. **This must be done to prevent damage to the cables.**
2. Disconnect the wires from the blower resistor (Fig. 6) and the blower motor.
3. Remove 5 screws attaching the air inlet (vent) duct to the heater housing (Fig. 6).
4. Remove clip attaching defroster duct to heater (Fig. 7). Disengage defroster duct from heater.
5. Disconnect the blower wires (Fig. 8).
6. Drain the radiator and remove the heater hoses from the heater core.
7. Remove 3 heater stud retaining nuts and remove heater (Fig. 8).

Installation

1. Position heater assembly in vehicle and install 3 stud retaining nuts.
2. Connect heater hoses to heater core and fill radiator.
3. Connect blower motor wires.

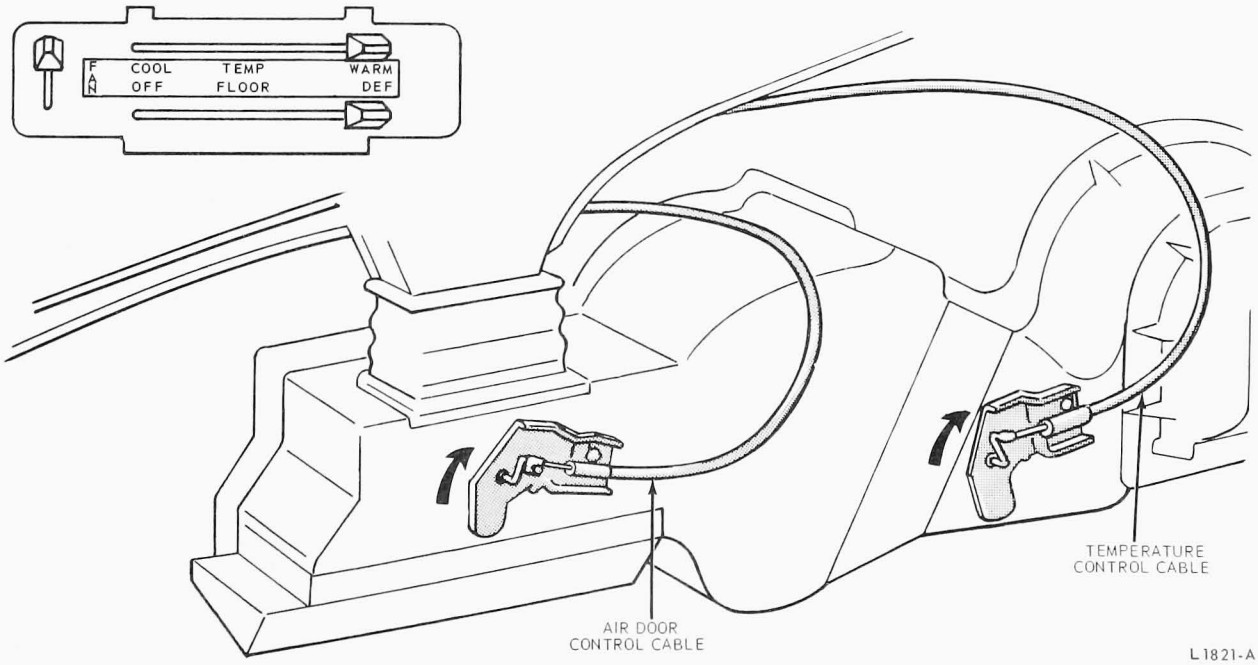

FIG. 5 Heater Control Cable Adjustments—F-100 Through F-350

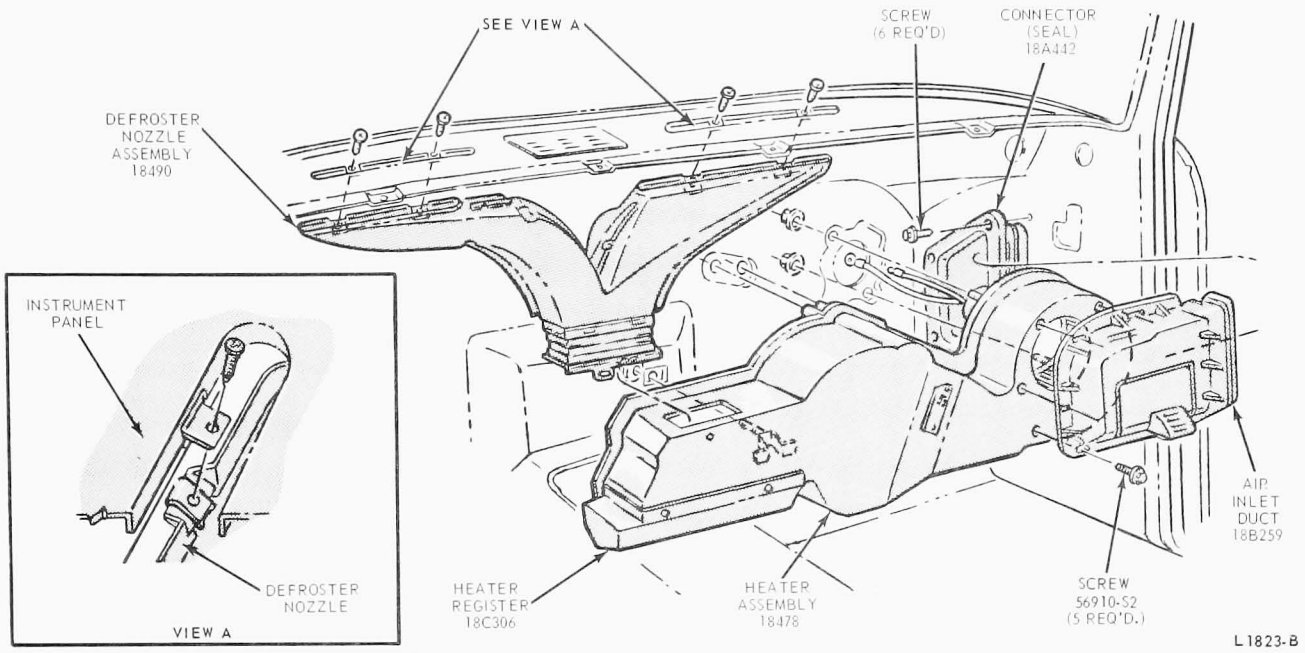

FIG. 6 Heater Installation—F-100 Through F-350

4. Connect defroster duct to plenum and install clip (Fig. 7).
5. Install air inlet (vent) duct to heater. Push duct firmly against seal on side cowl and tighten 5 attaching screws.
6. Connect wires to blower motor resistor and blower motor.
7. Connect temperature and air door cables to heater, and adjust the cables (Fig. 5).
8. Check heater operation.

HEATER CORE

F-100 THROUGH F-350

1. Remove heater assembly.
2. Remove heater core cover and gasket (4 screws).
3. Pull heater core and lower support from heater.
4. Install foam gaskets on heater core and install in heater assembly.
5. Install the core seal and cover plate.
6. Install heater in vehicle.

F-500 THROUGH F-750

1. Drain the cooling system and disconnect both heater hoses at the heater.
2. Remove the three nuts and washers that retain the heater assembly to the dash panel (Fig. 2).
3. Remove the glove box.
4. Remove the five screws that retain the air inlet duct to the cowl, pull the heater assembly from the dash panel, and disconnect both defroster nozzles from the heater.
5. Disconnect the wire lead to the blower motor and resistor.
6. Disconnect the control cables from the heater, and remove the assembly to a bench.
7. Remove the core cover stop bracket (8 retaining screws), remove the retaining clip, and remove the core from the case.
8. Transfer the pad to the new core (no glue), position the core in the case, and install the clip and core cover (8 retaining screws).
9. Position the heater assembly to the dash and cowl, and start one heater-to-dash retaining nut.
10. Connect the blower motor and resistor wire lead, and install the five duct-to-side cowl screws.
11. Connect and adjust the control cables, and connect the defroster nozzles to the heater.

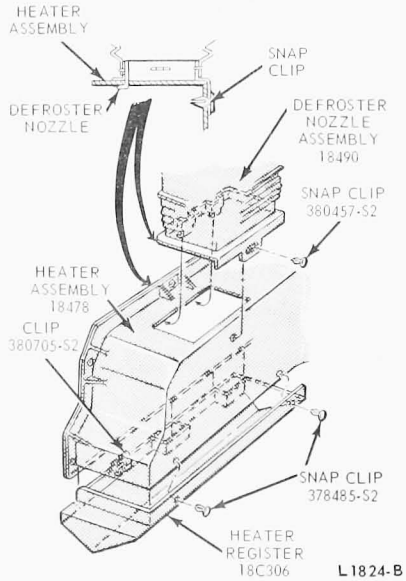

FIG. 7 Defroster Duct Attachment at Plenum—F-100-350

12. At the engine side of the dash panel, install the remaining two heater-to-dash nuts and tighten the one that was started in Step 9.
13. Position the pads to the core tubes, connect the heater hoses, and fill the cooling system.

L-SERIES

1. Drain the cooling system and disconnect both heater hoses at the core.
2. Disconnect the control cable at the top of the heater assembly (spring nut, clip and screw. See Fig. 3).
3. Disconnect the motor wire leads, and remove the heater front cover (12 retaining screws).
4. Pull the old core from the heater, transfer the core pads to the new core, and push the new core into the heater case.
5. Route the motor leads through the front of the cover assembly, position the cover to the heater, and install the twelve retaining screws.
6. Connect the motor leads.
7. Connect the control cable at the top of the heater assembly (clip, screw and spring nut). Adjust the cable.
8. Connect both heater hoses and fill the cooling system.

C-SERIES

1. Drain the coolant.
2. Disconnect the defroster hoses at the plenum chamber (Fig. 4).
3. Disconnect both blower motor wires at the connectors. Remove the glove box liner to gain access to the heater motor wire disconnects.
4. Disconnect the heater hoses at the heater.
5. Remove the heater lower mounting bolts, nuts and lock washers.
6. Remove the upper mounting screws and move the heater assembly away from the dash. Disconnect the Bowden cable from the air inlet door and remove the heater assembly from the truck.
7. Remove the top cover.
8. Remove the heater core mounting screws and remove the core from the housing.
9. Position the new core in the housing, install the mounting screws and install the top cover.
10. Position the heater assembly to the dash and connect and adjust the air door Bowden cable.
11. Install the upper mounting screws and the lower mounting bolts, lock washers and nuts.
12. Connect the heater hoses to the heater.
13. Connect both motor wires, color to color at the disconnects, and install the glove box liner.
14. Connect the defroster hoses at the plenum chamber. Install the coolant. Bleed any air from the heater core, check for leaks and check the heater operation.

HEATER CONTROL

F-100 THROUGH F-350

Removal

1. Disconnect the battery ground cable.
2. Pull the knob and disc off each radio control shaft.
3. Remove the fuel gauge switch knob (if so equipped), heater control knobs and wiper washer knob. Use a hook tool to release each knob lock tab.
4. Remove the knob and shaft from the lights switch.
5. Remove the nut and washer from each radio control shaft, and remove the radio bezel.
6. Remove the cluster bezel (Group 33). The attaching screws are located as follows: 4 screws along top of bezel; one screw between the lights and wiper-washer switch; and 2 screws below the radio. Then, disconnect the illumination light from the bezel between the lights and wiper-washer switch.
7. Remove 4 heater control attaching screws and pull the control away from the mounting bracket. Disconnect the blower switch and illumination light wires and the 2 Bowden cables from the control assembly.

Installation

1. Install the Bowden cables on the control assembly as shown in Fig 9. **The pigtail of the cable must point away from the control lever as shown.**
2. Connect the illumination light wires at the connector and the blower wire connector to the blower switch.
3. Position control assembly to mounting plate and install 4 screws.
4. Install the cluster bezel, radio bezel and all knobs.
5. Connect the ground cable to the battery and check operation of control assembly. Adjust the Bowden cables if necessary.

HEATER BLOWER SWITCH

F-500 THROUGH F-750

1. Remove the control knob from the switch shaft by loosening the set screw.
2. Disconnect the connector plug from the switch.
3. Disconnect the left defroster duct and position it out of the way in order to gain access to the heater control.
4. Remove the two heater control-toinstrument panel retaining nuts,

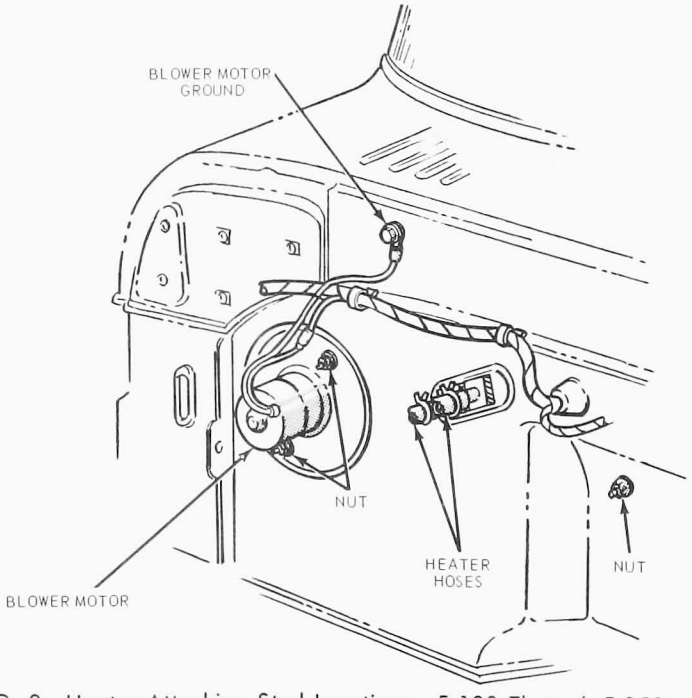

FIG. 8 Heater Attaching Stud Locations—F-100 Through F-350

and pull the control assembly out of the panel.
5. Remove the heater switch from the control assembly (1 retaining screw).
6. After installing the switch, test it for blower operation.

L-SERIES—LINE HAUL MODELS

1. Remove the battery box cover, and disconnect the ground cable.
2. Remove the strip that retains the instrument cluster side pad (4 screws), and swing the hinged pad down to gain access to the switch.
3. Remove the heater control assembly (4 retaining screws).
4. Remove the control knob from the switch shaft by loosening the set screw, disconnect the push-on connector, and remove the switch from the control assembly (1 retaining screw).

L-SERIES—CITY DELIVERY MODELS

Remove the control knob from the switch shaft by loosening the set screw. Reaching up under the instrument panel, disconnect the multiple connector. Remove the switch-to-heater control retaining screw and remove the switch from under the instrument panel.

C-SERIES

1. Remove the heater blower switch knob. The knob is held on the shaft by a set screw or by a spring clip. The spring clip type knob is removed by depressing the clip with a small screwdriver through a slot in the side of the knob.
2. Remove the switch from its mounting location with the wires attached. Transfer each wire spade connector to the new switch one at a time so as to connect the wires to the proper terminals.
3. Mount the switch and install the knob.

HEATER BLOWER MOTOR

F-100 THROUGH F-350

1. Remove the heater assembly.
2. Remove 2 screws and 2 nuts attaching blower to heater.
3. Remove blower fan from motor shaft, and remove motor from mounting plate.
4. Install new motor on mounting plate and install blower fan on motor shaft.
5. Install blower and motor in heater. Then, install the heater.

F-500 THROUGH F-750

1. Remove the glove box for access.
2. Disconnect the motor quick disconnect wire. Disconnect the ground wire at the top of the heater assembly (1 screw).
3. Remove the four retaining screws, and remove the blower motor and wheel assembly from the heater case.
4. Remove the blower wheel from the motor shaft by loosening the set screw.
5. Remove the motor from its mounting plate (2 retaining nuts).
6. Install the new motor to the mounting plate, assemble the blower wheel to the motor shaft, and install the assembly to the heater case.
7. Connect the power lead, install the ground wire screw, and check blower operation.
8. Install the glove box.

L-SERIES

1. Disconnect the control cable at the top of the heater assembly, and remove the spring nut, clip, and screw (Fig. 3).
2. Disconnect the motor electrical leads.
3. Remove the heater front cover (12 retaining screws).
4. Remove the screw that retains the motor to the mounting plate, rotate the motor to unlock it, and remove the motor and wheel assembly.
5. Remove the blower wheel from the motor shaft (1 set screw) and install it on the new motor.
6. Position the blower motor and wheel to the heater assembly mounting plate, rotate the motor to lock it in place, and install the retaining screw.
7. Route the wire leads through the front of the heater cover, install the cover, and secure with 12 retaining screws.
8. Connect the motor leads.
9. Connect the control cable at the top of the heater assembly, install the clip, screw, and spring nut, and adjust the cable.

C-SERIES

Removal and installation of the heater blower motor and blower wheel is accomplished as shown in Fig. 10 after first removing the blower housing front cover. After installing the blower and

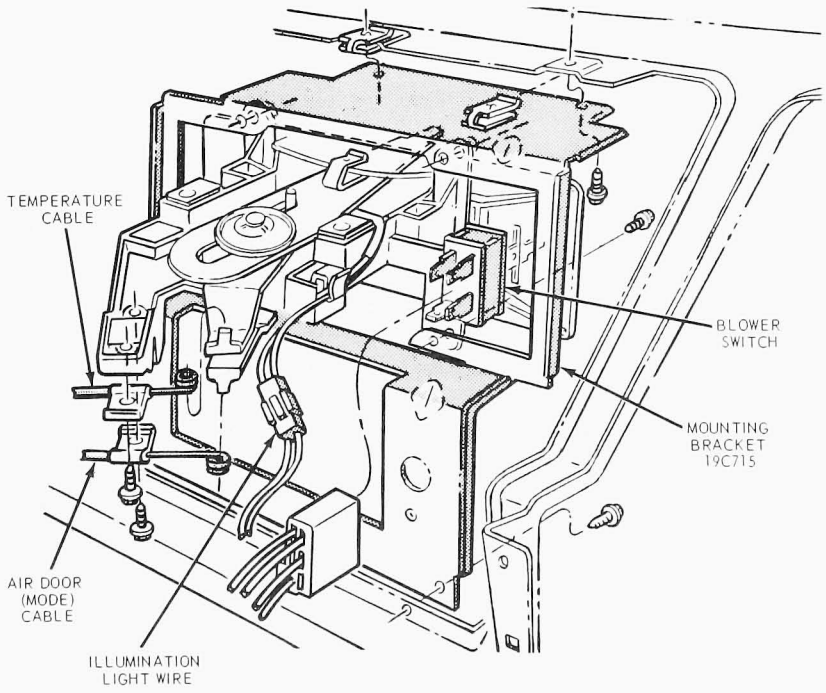

FIG. 9 Heater Control Assembly—Rear View—F-100 Through 350

fan, be sure that the ground connection is tight and makes good electrical contact.

PARCEL DELIVERY

Removal and installation of the heater blower motor and blower wheel can be accomplished, as shown in Fig. 11, after first removing the blower housing front cover. After installing the blower and fan, be sure that the ground connection is tight and makes good electrical contact.

HEATER WATER VALVE

F-500 THROUGH F-750

1. Partially drain the cooling system to just below the level of the valve.
2. Disconnect the temperature control cable from the heater water valve (screw and clip).
3. Disconnect both hoses from the valve and remove the valve.
4. After installing the valve, adjust the temperature control cable as outlined in Adjustments, start the engine and check for leaks.

L-SERIES

1. Drain the cooling system.
2. Disconnect the temperature control cable from the heater water valve (spring nut, clip and screw).
3. Disconnect both hoses from the valve, remove three valve-to-dash panel retaining screws, and remove the valve.
4. After installing the valve, adjust the temperature control cable.

HEATER TEMPERATURE CONTROL CABLE

F-500 THROUGH F-750

1. On the engine side of the dash, disconnect the battery ground cable, and disconnect the temperature control cable from the heater water valve.
2. In the cab, remove the glove box, the right defroster nozzle, and the ash tray with retainer for access to the heater control.
3. Remove the heater control assembly from the instrument panel (two retaining nuts).
4. Disconnect the temperature control cable from the heater control assembly (screw, clip, and spring nut).
5. Pull the control cable out of the vehicle from the engine side of the dash panel.
6. When installing, push the control cable through the dash panel from the engine side.
7. Set the control levers in the center position of the control head slot, and connect the cable to the heater control assembly. Install the heater control assembly to the instrument panel (two retaining nuts).
8. Connect the cable to the water valve, adjust the cable as outlined in Adjustments, and seat the grommet in the dash panel.

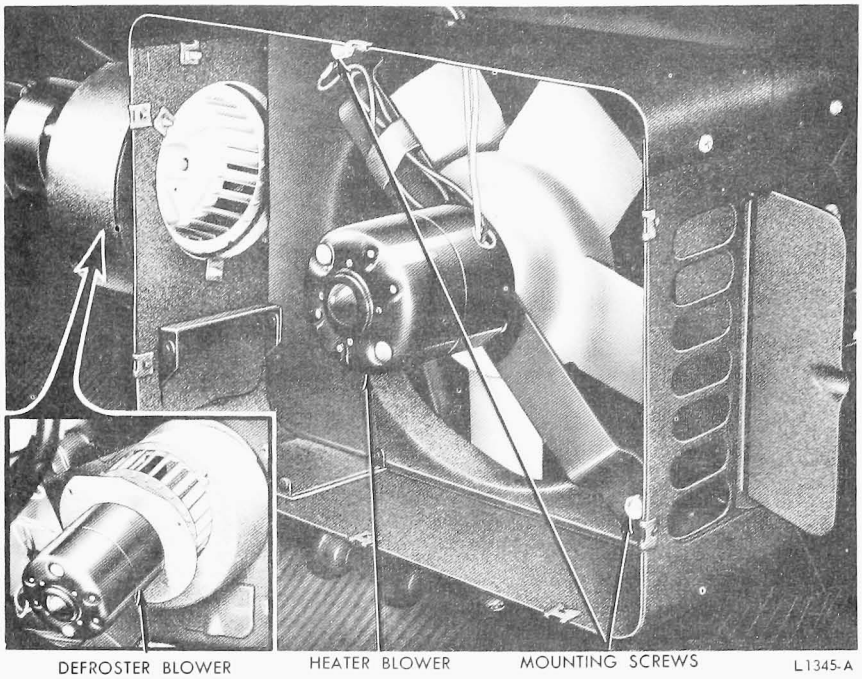

FIG. 10 Heater Blower Motor Removal—C-Series

HEATER BLOWER RESISTOR

F-100 THROUGH F-350

The blower resistor is mounted on the heater near the temperature door cable attachment. To replace the resistor, disconnect the wire connector and remove the two 2-piece snap clips retaining the resistor to the heater. Remove the center of the snap clip first. Then, remove the rest of the clip.

F-500 THROUGH F-750

1. Remove the glove box for access.
2. Through the glove box opening, remove the resistor top retaining screw. Also remove the resistor lower retaining screw from the left end of the heater by using a long 1/4-inch drive extension.
3. Pull the resistor out through the glove box opening, disconnect the wire, and remove the resistor.
4. Connect the new resistor to the wire, and install it through the glove box opening. Install the upper retaining screw.

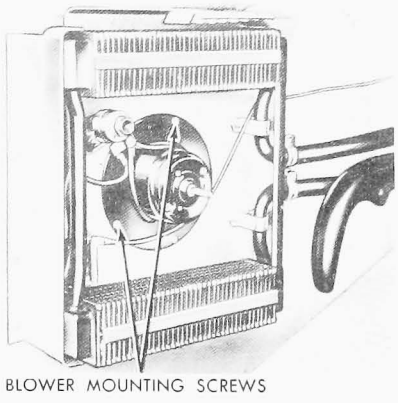

FIG. 11 Heater Blower Motor Removal—Parcel Delivery

5. Install the lower retaining screw from the left end of the heater using a long 1/4-inch drive extension. The screw can also be guided with the right hand through the lower opening of the heater.
6. Install the glove box, and test motor operation.

L-SERIES

The resistor is attached to the lower side of the heater assembly by two plastic retainers. Disconnect the plug and pry out the retainers to replace. Test motor operation after installation.

HEATER HOSE ROUTINGS

The heater hose routings for the light truck fresh air heater are shown in Fig. 12.

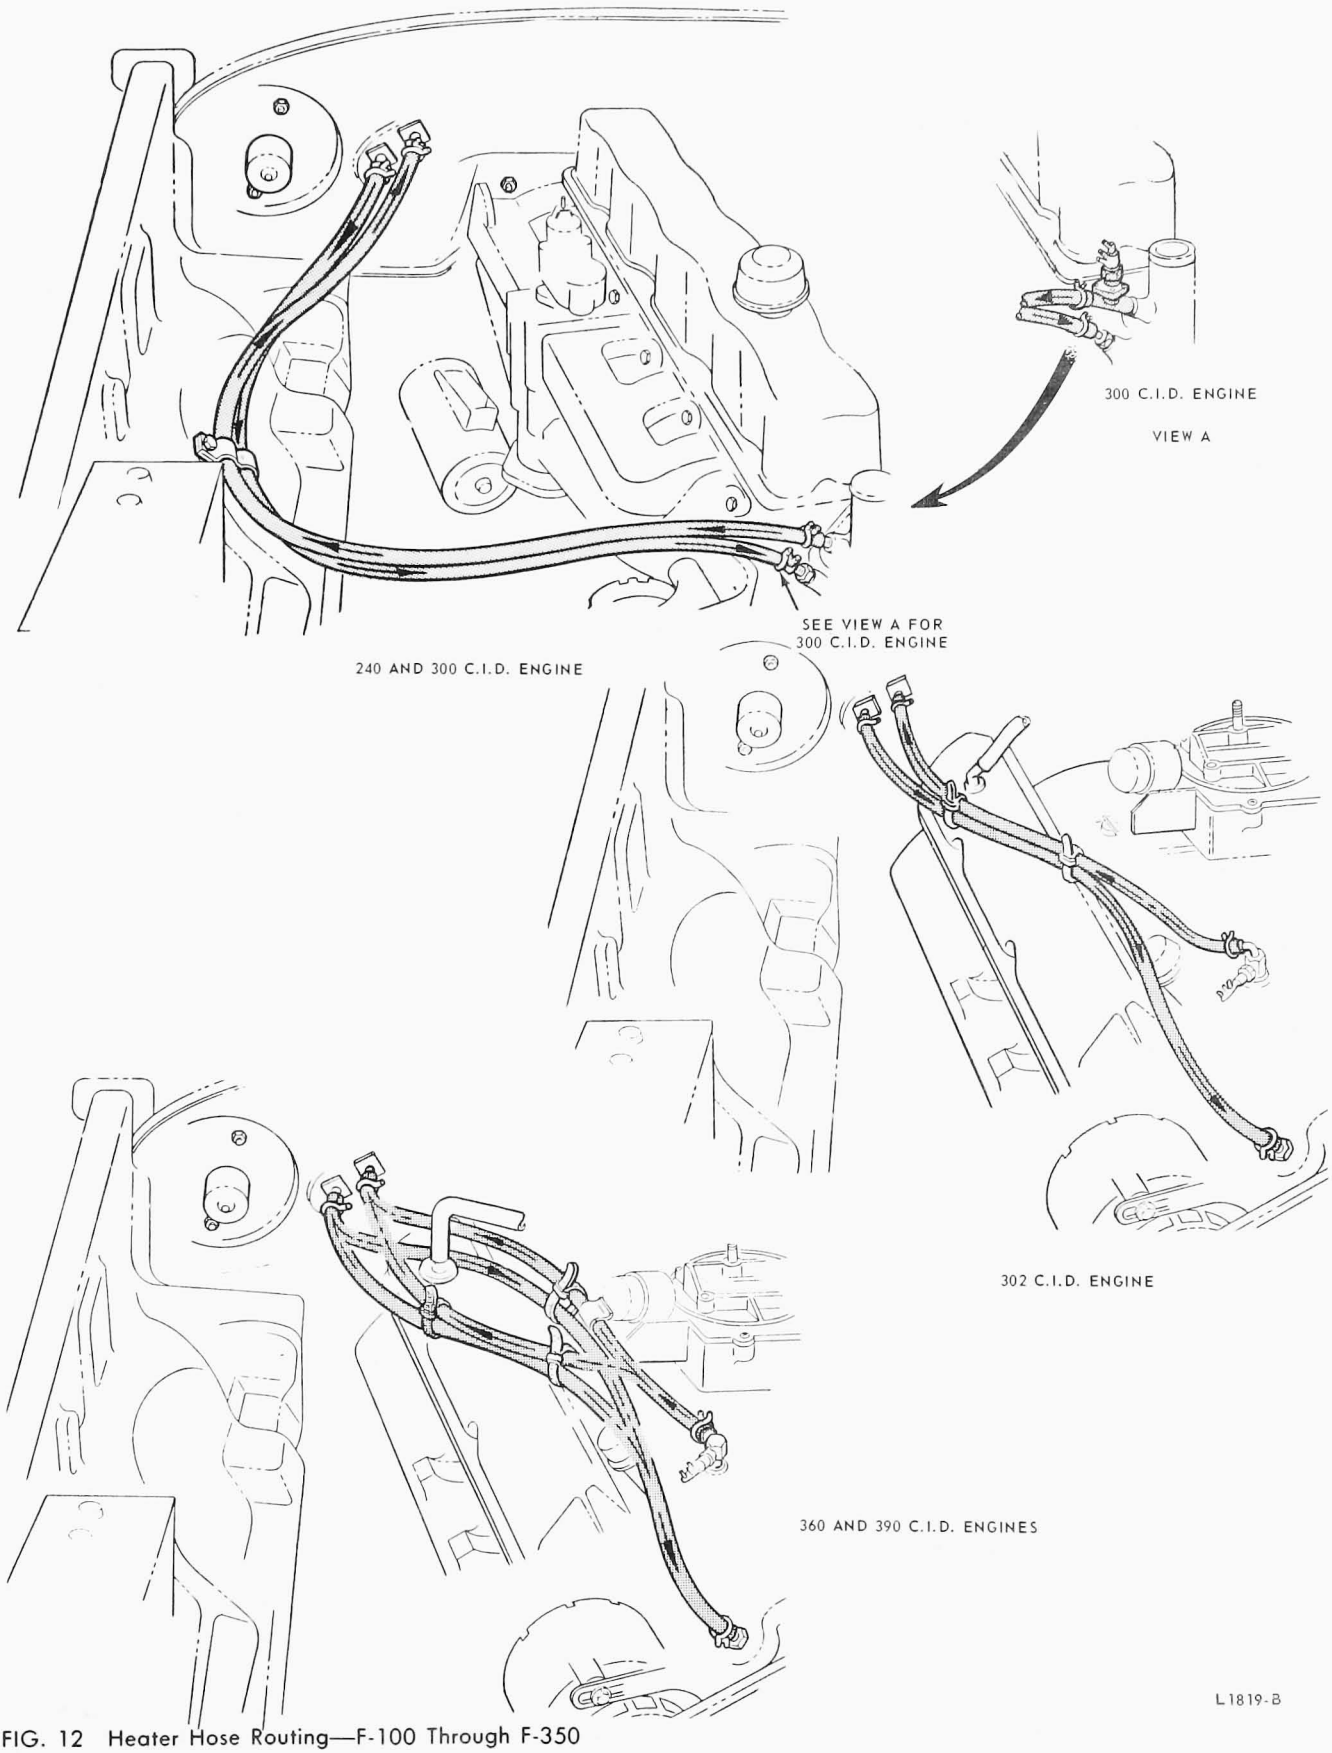

FIG. 12 Heater Hose Routing—F-100 Through F-350

PART 36-21 W- Series Truck Heating System

Applies To W-Series Trucks

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS		REMOVAL AND INSTALLATION	
Control Cables	21-01	Defroster Control Cable	21-02
Hot Water Control Valve	21-01	Heater Blower Motor	21-02
		Heater Core	21-03
DESCRIPTION AND OPERATION	21-01	Heater Control Cable and Switch	21-01

DESCRIPTION AND OPERATION

The heater is a fresh air type heater and is located to the right of the fuse and/or circuit breaker console. All parts of the heater can be serviced from within the truck cab except the heater water hoses and the manual water shut-off valve, which are serviced from the underside of the cab.

There are three controls mounted on the left side of the heater. The forward-most control operates a fresh-air damper door and is used to supply fresh air for heater operation. This door should be open for heater operation (control pulled out).

The second knob is a dual purpose control which operates the hot-water control valve for heater operation and provides a three-speed operation of the double centrifugal blower. This water control valve should not be confused with the manual water shut-off valve located at the engine water outlet. Pull the control out to increase heater air temperature. Push the control all the way in to shut the heater off for summer operation.

The third knob is labeled as the **DEFROST** control. This control should be pulled out for maximum defroster operation. When the control is pushed in, heater air is directed toward the cab floor with a minimum of defroster air. To obtain spot defrosting, rotate the frog eyes on the top of the unit to direct air to the desired location on the windshield. The frog eyes can be rotated 360 degrees and pivoted up or down to any one of five positions. They are most effective with the defrost control knob pulled out (defrost position).

ADJUSTMENTS

HOT WATER CONTROL VALVE

Check the operation of the hot water control valve. When the control knob is pushed in, the valve should shut off. Adjust the Bowden cable as necessary so the valve is off when the control knob is pushed in.

CONTROL CABLES

The defrost doors, air doors, and water valve controls must be adjusted so that the doors and valves are at the end of their travel when the control knobs are all the way in.

Loosen the Bowden cable retaining screw at the air door or valve control, move the cable housing back and forth until the air door or valve is at the end of its travel when the knobs are 1/16-1/8-inch from the in position, then tighten the retaining screw.

REMOVAL AND INSTALLATION

HEATER WATER VALVE CONTROL CABLE AND BLOWER SWITCH ASSEMBLY

Removal

1. Remove the heater grille retaining screws and grille.
2. Remove the heater top cover secured by retaining screws (Fig. 1).
3. Remove the control knob.
4. Remove the nut retaining the switch and cable assembly.
5. Disconnect the switch push-on connectors.
6. Remove the clip at the water control valve and remove the cable and switch assembly.

Installation

1. Position the new switch and cable assembly and install the retaining nut (Fig. 1).
2. Install the control knob.
3. Install the clip at the water control valve. Adjust and tighten the valve retaining screw.

4. Connect the switch with push-on connectors.
5. Install the heater top cover with retaining screws.

DEFROSTER CONTROL CABLE

Removal

1. Remove the retaining screws and heater register (Fig. 1).
2. Remove the heater top cover secured by retaining screws.
3. Remove the screw and clip retaining the cable to the top of the heater, and position the cable out of the defroster door.
4. Remove the nut retaining the cable to the side of the heater and remove the cable assembly.
5. Transfer the control knob.

Installation

1. Position the defroster cable to the heater and install the retaining nut.
2. Position the cable to the door. Adjust the cable and install the clip and screw.
3. Install the heater top cover.
4. Install the heater grille.

HEATER BLOWER MOTOR

1. Remove the retaining screws and heater register (Fig. 1).
2. Remove the heater top cover secured by retaining screws.
3. Remove the cable retaining clip and disconnect the cable at the fresh air door.
4. Remove the retaining nut and remove the fresh air door cable from the heater assembly.
5. Remove the cemented seal from the top of the blower housings.
6. Remove the clip retaining the defroster door cable to the heater housing and disconnect the cable at the defroster door.
7. Remove the nuts securing the motor strap and motor ground wire.
8. Disconnect four wires at the heater switch.
9. Remove the screws securing the blower housings to the heater housing and center plate.
10. Remove the blower housings, motor and cages as a unit.
11. Remove the screws from the right and left sides of the blower-housing-to-motor mounting brackets and separate the housings from the motor and cages.
12. Remove the right and left cages from the motor shaft secured by Allen screws.
13. Transfer the two mounting brackets to the new motor and secure with nuts.
14. Install the cages to the motor shaft with Allen screws.
15. Position the right and left blower housings to the brackets on the motor and secure with four screws on each side.
16. Position the blower housings, motor and cage assembly into the heater housing.
17. Install four screws right and left side, blower housings to heater housing. These screws also retain the center plate.
18. Connect the four motor wires to the switch.
19. Position the motor strap around the motor and to the heater housing and install two nuts. One nut also retains the motor ground wire.
20. Connect and adjust the cable to the defroster door and install the clip.
21. Position the fresh air door cable to the heater housing and install the retaining nut loose. Connect the cable to the door then tighten the nut.
22. Install and adjust the fresh air door cable clip.
23. Cement the seal across the top of the blower housings.
24. Install the heater top cover and side grille with screws.

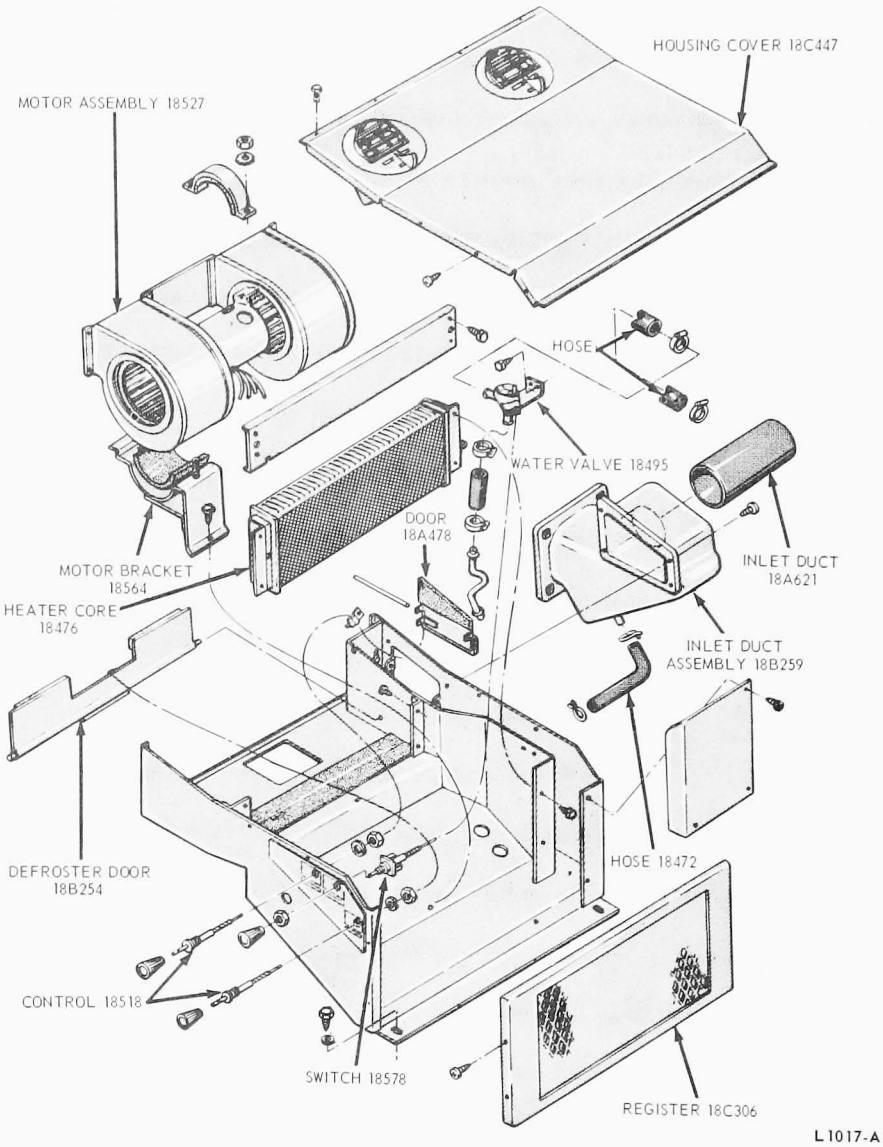

FIG. 1 W-Series Heater Disassembled

HEATER CORE

Removal

1. Drain the coolant.
2. Unlock and tilt the cab.
3. Disconnect both heater hoses at the core and control valve tubes.
4. Lower the cab.
5. Remove the top cover from the heater assembly.
6. Remove the register from the side of the heater assembly (Fig. 1).
7. Remove the cable retaining clip and disconnect the cable at the fresh air door.
8. Remove the retaining nut and remove the fresh air door cable from the heater assembly.
9. Remove the seal from the top of the blower housings.
10. Remove the clip (1 screw) retaining the defroster door cable to the heater housing and disconnect the cable at the defroster door.
11. Remove the blower motor hold-down strap secured by two nuts (Fig. 1). One nut also retains the blower motor ground wire.
12. Disconnect four wires at the heater switch.
13. Remove eight screws securing the blower housings to the heater housing and center plate.
14. Lift out the blower housings, motor and cages as a unit.
15. Remove the defroster door pivot plate secured by six screws.
16. Remove the heater core top retaining plate secured by five screws. Note the defroster door cable routed between the plate and the core.
17. Remove the three screws securing the heater core to the left side of the heater assembly.
18. Remove the clip from the switch and control valve cable and disconnect the cable at the valve.
19. Remove two screws securing the valve and bracket to the heater housing.
20. Lift out the core, valve and bracket as a unit, from the heater assembly.
21. Transfer the valve, bracket and hose to the new heater core. (Disconnect the valve hose at the core tube.)

Installation

1. Position the core, valve and bracket as a unit into the heater housing.
2. Install the valve and bracket to the heater housing and secure with two screws.
3. Position the defroster door pivot plate to the heater housing and secure it with screws.
4. Install screws on the left side securing the heater core to the heater housing.
5. Install the heater core top retaining plate. Route the defroster door cable between the plate and the core.
6. Connect the control cable to the control valve.
7. Install the valve control cable retaining clip and adjust the valve control cable.
8. Position the blower housing, motor and cages into the heater housing as a unit.
9. Install the right and left blower housings to the heater housing. One screw also retains the center plate.
10. Connect the four wires to the switch.
11. Install the motor retaining strap along with the motor ground wire.
12. Connect the cable to the defroster door and adjust it. Install the retaining clip.
13. Position the fresh air door cable to the heater housing and install the retaining nut loose. Connect the cable to the door then tighten the nut.
14. Install and adjust the fresh air door cable clip.
15. Cement the seal across the top of the blower housings.
16. Install the heater top cover and side grille with screws.
17. Tilt the cab.
18. Connect both heater hoses.
19. Lower and lock the cab.
20. Fill the cooling system and check the heater operation.

PART 36-22 Bronco Heating System

Applies To Bronco

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS		REMOVAL AND INSTALLATION	
Control Cables	22-03	Air Door Control Cable and Blower Switch Assembly	22-04
DESCRIPTION AND OPERATION		Blower Motor	22-04
Air Flow	22-01	Heater Core	22-03
Control Operation	22-01		

DESCRIPTION AND OPERATION

AIR FLOW

Outside air enters the heater assembly through an air duct in the right cowl, flows through the blower and the heater core fins into the plenum chamber, and discharges through the defroster nozzles and/or the floor outlet (Fig. 1).

When the blower is **off,** the air is forced through the system by the forward motion of the vehicle. When the blower is **on,** it increases the air flow by drawing the air from the inlet duct and forcing it through the heater core.

When hot engine coolant flows through the heater core, the air is heated as it passes through. When the heater water valve shuts off the flow of coolant through the core, the air passes through and discharges unheated for fresh air ventilation.

CONTROL OPERATION

The temperature (right) control (Fig. 2) operates a cable connected to the heater water valve (Fig. 1). Pushing the knob in closes the water valve shutting off the flow of hot coolant from the engine through the heater core (no heat). Pulling the knob out opens the valve to allow flow of hot coolant through the core. The farther out the knob is pulled, the greater the coolant flow and the higher the temperature. At full out position, the water valve is wide open (maximum heat).

The center control knob performs two functions: it actuates a cable connected to the outside air door; and it controls the blower motor switch. Pulling the knob **out** opens the outside air door allowing outside air to flow through the heater core into the plenum chamber. Pushing the knob in shuts off air flow. With the knob turned left to OFF position, the blower is off and outside air is forced through the system by the forward motion of the vehicle only. Turning the knob to the right (HI or LO blower speeds) increases the flow of air through the system.

The heat/defrost (left) control knob actuates a cable connected to the heat/defrost door (Fig. 1). When the knob is **pulled out,** the door directs discharged air through the defroster nozzles to the windshield. When the knob is **pushed in,** the control door directs air through the floor outlet to the passenger compartment. Pulling the knob part way out, directs part of the discharge air to the windshield and part to the floor.

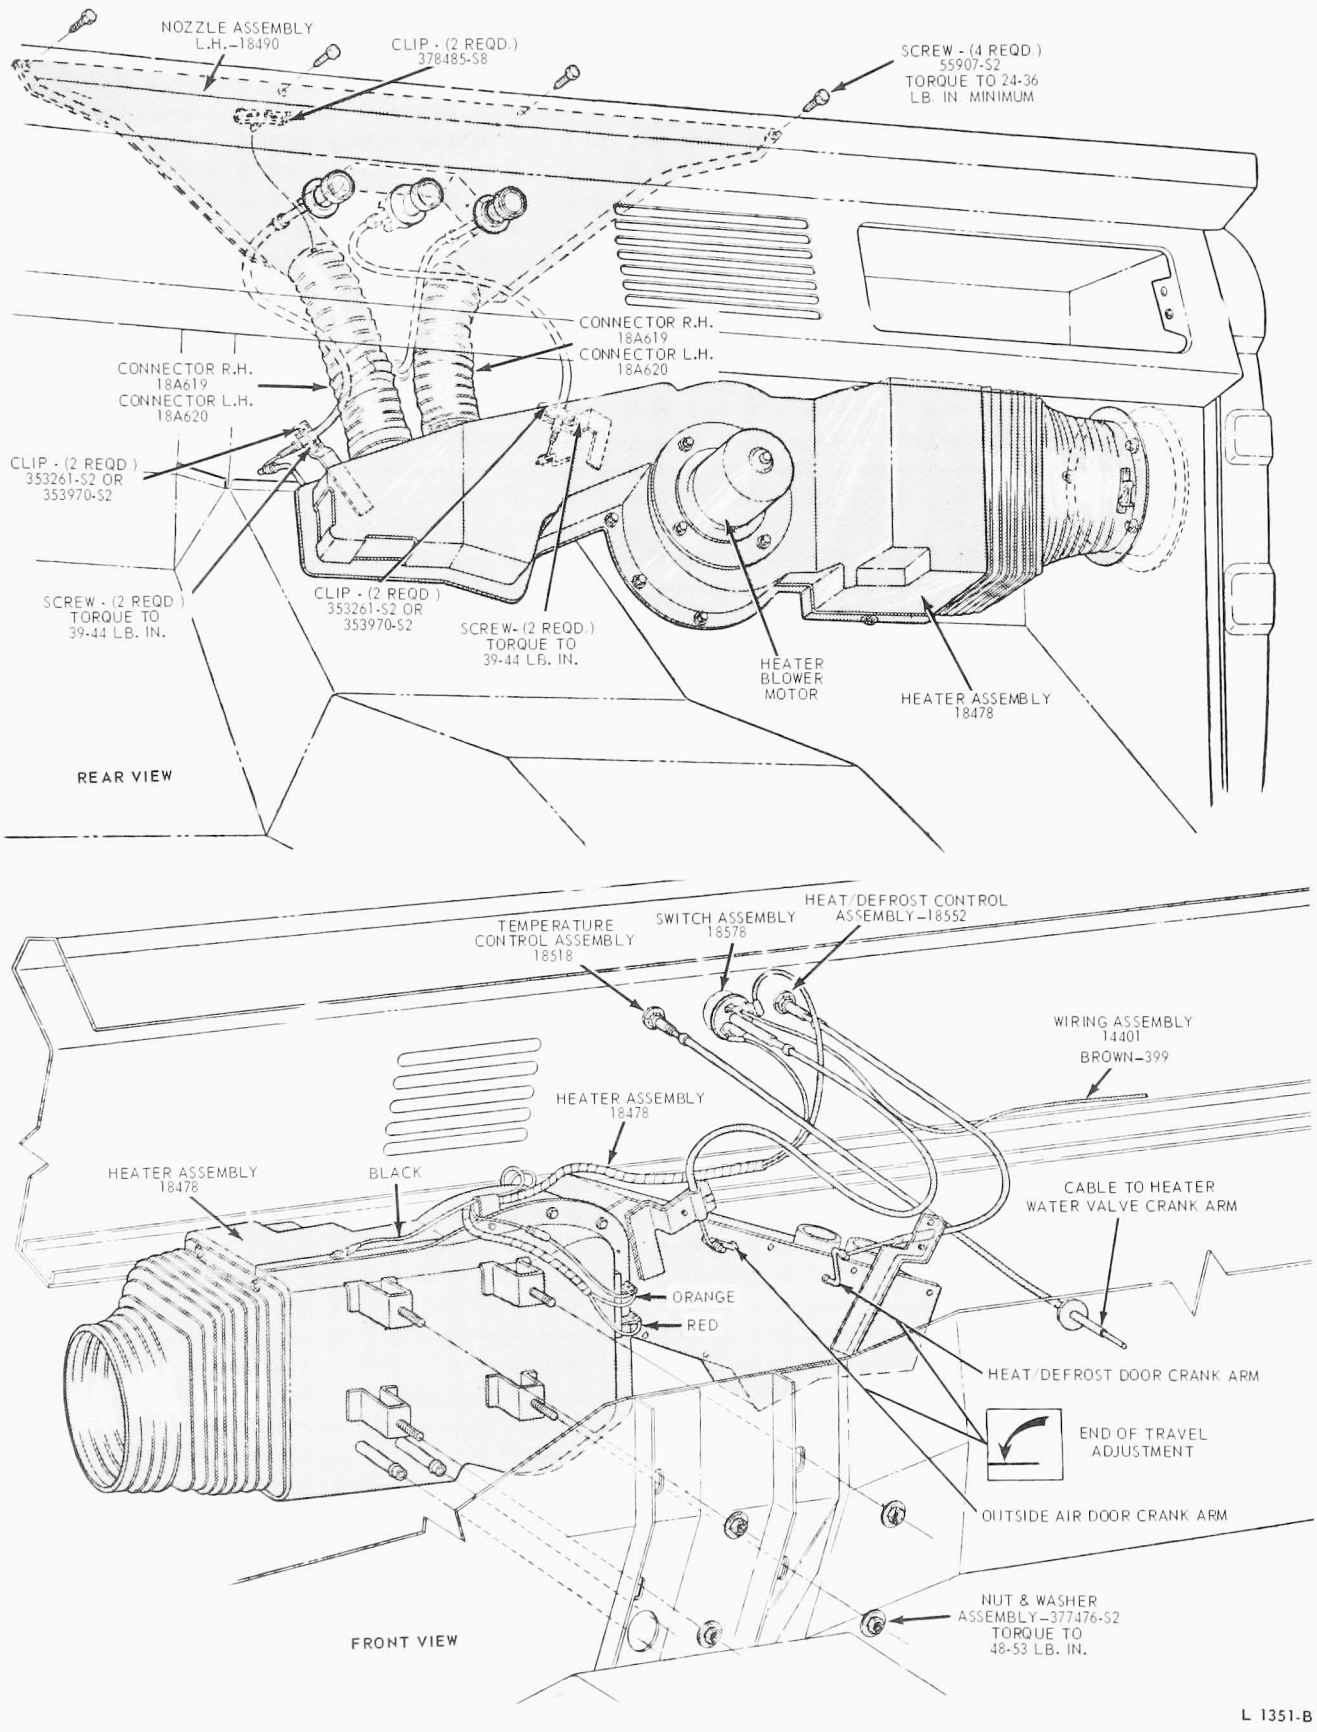

FIG. 1 Heater Installation—Bronco

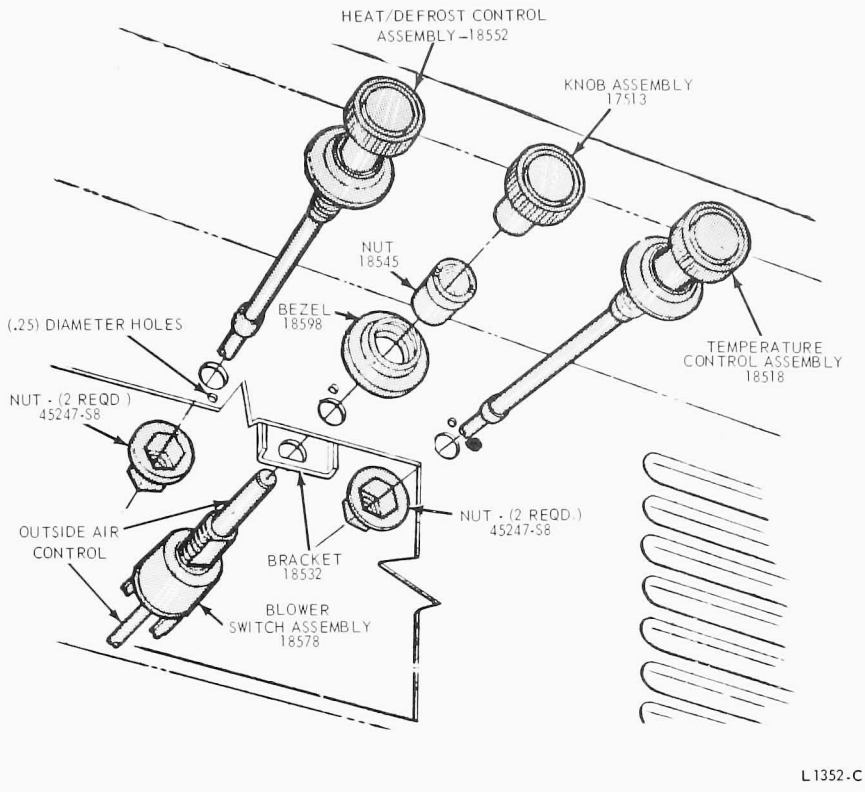

FIG. 2 Heater Controls—Bronco

ADJUSTMENTS

CONTROL CABLES

The heat/defrost door, outside air door, and water valve control cables must be adjusted so that the doors and valve are at the end of their travel when the control knobs are 1/16 to 1/8-inch from the end of their travel (fully pushed-in position).

Loosen the Bowden cable retaining clip screw at the air door or valve crank arm (Fig. 1). Move the cable housing back and forth until the crank arm is at the end of its travel as shown in Fig. 1 when the knobs are 1/16 to 1/8-inch from the fully pushed-in position. Then, tighten the retaining screw.

REMOVAL AND INSTALLATION

HEATER CORE

1. Drain the cooling system.
2. Disconnect both heater hoses at the heater (Fig. 1). Remove the rubber pads from the core.
3. Remove the nuts and star washers retaining the heater assembly to the dash panel.
4. Disconnect the right and left defroster hoses at the plenum.
5. Disconnect the fresh air inlet at the cowl. Rest the heater on the floor.
6. Disconnect the heat/defrost door cable at the door crank arm (Fig. 1).
7. Disconnect the outside air door cable at the crank arm.
8. Disconnect the electrical wires at the connector.
9. Remove the heater assembly from the vehicle.
10. Remove the screws retaining the rear cover. Remove the clip retaining the core in the case and remove the core.
11. Transfer the seals from the heater core to the new core.
12. Position the core in the case. Install the retaining clip. Position the cover and install the retaining screws.
13. Position the heater assembly on the floor in the vehicle. Connect the wire connectors.
14. Connect and adjust the outside air door control cable.
15. Connect and adjust the heat/defrost door control cable.
16. Position the heater assembly to the dash and install the nuts and washers.
17. Position the heater core pads over

the core and connect both hoses.
18. Connect the defroster hoses and fresh air intake.
19. Fill the cooling system.
20. Check the heater operation and check for leaks.

HEATER BLOWER MOTOR

1. Disconnect the electrical connectors and the ground wire from the top of the heater.
2. Remove the screws retaining the motor to the plenum chamber, and remove the motor assembly (Fig. 1).
3. Loosen the blower wheel Allen screw.
4. Remove the motor from the mounting plate.
5. Install the motor to the mounting plate.
6. Install the blower wheel.
7. Position the motor to the plenum. Install the retaining screws.
8. Connect the electrical lead and the ground wire.
9. Check the operation of the blower.

OUTSIDE AIR DOOR CONTROL CABLE AND BLOWER SWITCH ASSEMBLY

1. Remove the control knob (center control, Fig. 2). Push up on the clip in the knob to remove it.
2. Remove the blower control switch bezel nut and the bezel (Fig. 2).
3. Disconnect the cable from the outside air door crank arm (retaining clip and screw).
4. Disconnect the motor high and low speed lead wires at the switch assembly.
5. Remove the heater control switch and cable assembly with the retainer from the underside of the instrument panel.
6. Connect the motor high and low speed lead wires to the switch assembly.
7. Position the heater switch and cable assembly with retainer to the back of the instrument panel and install the bezel and bezel retaining nut.
8. Install the heater control switch knob.
9. Connect the cable to the outside air door crank arm and install the retaining clip and screw (Fig. 1).
10. Adjust the cable as outlined in Adjustments.

PART 36-23 Econoline Heating System

Applies To Econoline

COMPONENT INDEX	Page
ADJUSTMENTS	
Heater Controls	23-01
DESCRIPTION AND OPERATION	
Auxiliary Hot Water Heater	23-01
Fresh Air Heater	23-01

COMPONENT INDEX	Page
REMOVAL AND INSTALLATION	
Auxiliary Hot Water Heater	23-02
Heater Core and/or Blower Motor	23-01
Heater Switch	23-02

DESCRIPTION AND OPERATION

FRESH AIR HEATER

The fresh air heater is designed to operate in conjunction with the right side fresh air ventilating system. The left fresh air duct is located on the dash panel at the left side. Slide the door open for fresh air. The heater assembly attaches to the air inlet located on the right side of the dash. Controls for the heater are located in the instrument panel to the right of the instrument cluster.

The temperature control is the left lever. Pushing the lever down increases the amount of air flowing through the heater core, and thus increases the temperature. Engine coolant flows through the heater core at all times.

The defrost control is the right lever. Pushing the lever down opens the defroster outlets.

AUXILIARY HOT WATER HEATER

The auxiliary hot water heater is a recirculating type heater which provides additional heat for the rear seat area.

A combination water temperature control and blower switch is the only control used for the auxiliary heater and is located on the instrument panel. Engine coolant flow through the heater core is increased in proportion to the amount the control is pulled out to give more heat. Blower operation is controlled by rotating the knob. However, the auxiliary heater blower will not operate until the engine coolant temperature is near the enggine thermostat opening temperature. This is controlled by a thermostat switch connected to the fresh air heater hot water hose.

ADJUSTMENTS

HEATER CONTROLS

The defrost door and air door must be adjusted so that each door is at the end of its travel when the control knob is 1/16 to 1/8-inch from the end of its travel (up position).

Remove the glove box (and radio, if so equipped) to provide access to the heater control. Loosen the Bowden cable retaining screw (Fig. 2) on the heater control. Move the heat (left) control lever into the detent at the OFF position. Then, adjust the heater door bellcrank to the closed position by rotating the top of the crank toward the rear of the vehicle (Fig. 1). Tighten the Bowden cable retaining screw.

To adjust the defroster door, disconnect the defrost door control cable from the ball-joint on the control. With the control lever in the detent at the OFF position, push the link up to close the defroster door. Adjust the link length so that it will snap back on the ball-joint.

REMOVAL AND INSTALLATION

HEATER CORE AND/OR BLOWER MOTOR

1. Open the hood and remove the battery to gain access to the heater mounting bolts.
2. Drain the cooling system.
3. Disconnect the heater hoses at the heater (Fig. 1).
4. Disconnect the heater resistor and motor leads.
5. From under the hood remove the three heater-to-dash mounting bolts. Then, move the heater out of position to gain access to the control cable and disconnect the cable. Remove the heater assembly to a bench.

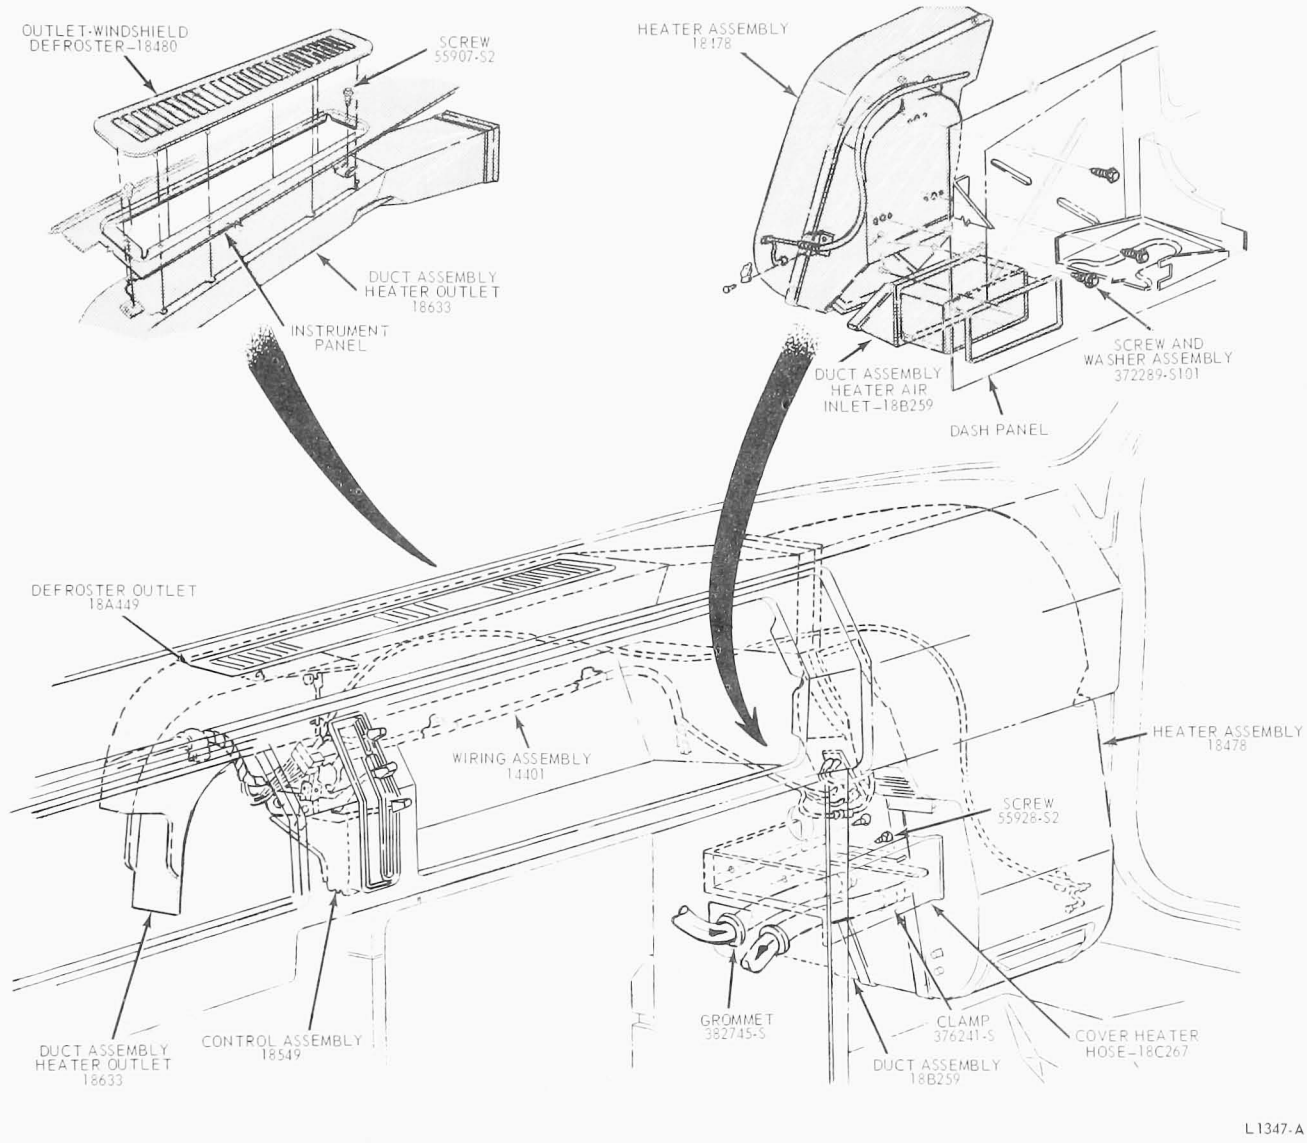

FIG. 1 Heater Installation—Econoline

6. Separate the two halves of the heater case (16 screws and one clip).

For heater core replacement, use Steps 7, 8 and 14 through 18.

7. Remove the heater core.
8. Transfer the core pads to the new core, and position the core in the case.

For blower motor replacement, use Steps 9 through 18.

9. Remove two screws and lift the motor and wheel from the front half of the heater housing.
10. Remove the blower wheel and motor mounting bracket.
11. Position the new motor in the mounting bracket and install the mounting bolts and nuts.
12. Install the blower wheel.
13. Position the motor assembly in the housing and install the mounting screws.
14. Position both halves of the case together and install the screws and clip.
15. Place the heater controls in the OFF position. Place the heater on the wheel housing as near the installed position as possible. Pull the air door closed (toward rear of vehicle) and connect the control cable.
16. Position the heater to the dash, and install the three mounting bolts. Use an assistant and make certain that the housing openings line up with the defroster and fresh air openings.
17. Connect the resistor and motor leads.
18. Connect the heater hoses.
19. Install the battery and fill the cooling system.

HEATER SWITCH

1. Remove the switch, heat and defroster knobs.
2. Remove the glove box, or radio if so equipped.
3. Remove the control front finish panel by removing the retaining clip at the bottom of the panel (Fig. 2).
4. Remove the engine cover, and remove the lower screw retaining the heater control to the lower edge of the instrument panel.
5. Remove the upper retaining screw in the face of the instrument panel and remove the control through the glove box opening after disconnecting the defroster control link at the ball joint.

6. Remove the screw retaining the heater switch, and disconnect the wiring plug.
7. Position the new switch to the control and install the retaining screw. Connect the wiring plug.
8. Position the control to the instrument panel and install the upper and lower retaining screws (Fig. 2).
9. Install the front finish cover. Slip the upper retaining projection in place and install the retaining clip at the bottom.
10. Install the control knobs, the glove box (or radio) and the engine cover.

AUXILIARY HOT WATER HEATER HEATER CORE AND/OR BLOWER MOTOR

Removal

1. Disconnect the battery ground cable.
2. Raise the vehicle on a hoist.
3. Remove the two hoses from the heater core and plug the hoses (Figs. 3 and 4).
4. Remove the rubber insulators from the heater core tubes.
5. Remove the four nuts from the heater assembly retaining studs.
6. Lower the vehicle.
7. Disconnect the two electrical leads at the heater assembly.
8. Remove the heater from the vehicle.

Installation

1. Position the heater assembly in the vehicle, inserting the mounting studs through the floor pan (Fig. 4).
2. Connect the two electrical leads at the heater assembly.
3. Raise the vehicle on a hoist.
4. Install the four nuts on the heater assembly retaining studs.
5. Install the rubber insulators on the heater core tubes.
6. Remove the plugs from the heater hoses and install the hoses on the heater core tubes securing them with clamps.
7. Lower the vehicle.
8. Add required coolant to the cooling system.
9. Connect the battery ground cable.

This Part gives the basic principles and service procedures that apply to all Ford Truck Air Conditioning systems. Each of the following parts (beginning with Part 36-40) covers only those procedures that are peculiar to the indicated vehicle system. **Reference both to this Part and to the Part covering the pertinent vehicle line is necessary for complete coverage of any given system.**

DESCRIPTION AND OPERATION

BASIC PRINCIPLES

Truck air conditioning is the cooling or refrigeration of the air in the passenger compartment. Refrigeration is accomplished by making practical use of three laws of nature. These laws of nature and their practical application are outlined in the following paragraphs.

HEAT TRANSFER

If two substances of different temperature are placed near each other, the heat in the warmer substance will always travel to the colder substance until both are of equal temperature. For example, a cake of ice in an ice box does not communicate its coldness to the bottle of milk standing nearby. Rather, in obedience to nature's law, the heat in the warm milk automatically flows into the ice which has a lesser degree of heat.

In order to determine the amount of heat that transfers from one substance to another, science has established a definite standard of measurement called the British Thermal Unit or BTU. One BTU is the amount of heat required to raise the temperature of one pound of water 1 degree F. For example, to raise the temperature of one pound of water from 32 degrees F to 212 degrees F, one BTU of heat must be added for each degree rise in temperature or a total of 180 BTU's of heat. Conversely, in order to lower the temperature of one pound of water from 212 degrees F to 32 degrees F, 180 BTU's of heat must be removed from the water.

LATENT HEAT OF VAPORIZATION

When a liquid boils (changes to a gas) it absorbs heat without raising the temperature of the resulting gas. When the gas condenses (changes back to a liquid), it gives off heat without lowering the temperature of the resulting liquid.

For example, place one pound of water at 32 degrees F in a container over a flame. With each BTU of heat that the

water absorbs from the flame, its temperature rises 1 degree F. Thus, after it has abosrbed 180 BTU's of heat, the water reaches a temperature of 212 degrees F. Here the law of nature is encountered. Even though the flame continues to give its heat to the water, the temperature of the water remains at 212 degrees F. The water, however, starts to boil or change from the liquid to the gaseous state, and it continues to boil until the water has passed off into the atmosphere as vapor. If this vapor were collected in a container and checked with a thermometer, it also would show a temperature of 212 degrees F. In other words, there was a rise of only 180 degrees F (from 32 to 212) in the water and vapor temperature even though the flame applied many more than 180 BTU's of heat. In this case, the heat is absorbed by the liquid in the process of boiling and disappears in the vapor. If the vapor were brought in contact with cool air, the hidden heat would reappear and flow into the cooler air as the vapor condensed back to water. Scientists refer to this natural law as the latent (hidden) heat of vaporization.

Water has a latent heat of vaporization of 970 BTU's and a boiling point of 212 degrees F. This means that one pound of water at 212 degrees F, will absorb 970 BTU's of heat in changing to vapor at 212 degrees F. Conversely, the vapor will give off 970 BTU's of heat in condensing back to water at 212 degrees F.

This tremendous heat transfer, that occurs when a liquid boils or a vapor condenses, forms the basic principle of all conventional refrigeration systems.

For a liquid to be a good refrigerant, the amount of heat that it absorbs when vaporizing is not the only factor. It must also have a low boiling point. That is, the temperature at which it boils must be lower than the substance to be cooled. To illustrate with water, place a bottle of milk at room temperature (70 degrees F) next to boiling water (212 degrees F). The The heat would flow from the (higher temperature) water to the (lower temperature) milk. The milk would be heated rather than cooled, **because the boiling point of water is too high.**

In order to make practical use of the heat transfer that takes place when a liquid boils, we must choose a liquid with a **low boiling point.** Refrigerant 12 is the liquid most commonly used in automotive air conditioning systems because it boils at 21.7 degrees F below zero. Here is a liquid that boils or vaporizes well below passenger compartment temperatures and, in vaporizing, will absorb tremendous amounts of heat without getting any warmer itself.

EFFECT OF PRESSURE ON BOILING OR CONDENSATION

The temperature of a liquid or vapor increases or decreases according to the pressure exerted on it.

In any Ford air conditioning system, liquid refrigerant (R-12) is stored in the receiver under high pressure (Fig. 1). When the liquid R-12 is released into the evaporator by the expansion valve the resulting decrease in pressure lowers its temperature to 21.7 degrees F (below zero), its boiling point. As the R-12 flows **through** the evaporator coils, passenger compartment air passes over the **outside surface** of the coils. As it boils, the R-12 absorbs heat from the air and thus cools the passenger compartment. The heat from the passenger compartment is absorbed by the boiling refrigerant and hidden in the vapor. The refrigeration cycle is now under way. To complete the cycle, the following remains to be done:

(1) Dispose of the heat in the vapor.
(2) Convert the vapor back to liquid for re-use.
(3) Return the liquid to the starting point in the refrigeration cycle.

The compressor (Fig. 1) performs these functions. It pumps the refrigerant (containing the hidden heat) out of the evaporator and forces it under high pressure into the condenser which is located in the outside air stream at the front of the car. The increased pressure in the condenser raises the R-12 vapor temperature to a point higher than that of the outside air. As the heat transfers from the hot vapor to the cooler air, the R-12 condenses back to a liquid. The liquid under high pressure now returns to the reservoir where it is stored for re-use.

It may seem difficult to understand how heat can be transferred from a comparatively cooler passenger compartment to the hot outside air. The answer lies in the difference between the refrigerant pressure that exists in the evaporator and the pressure that exists in the condenser. In the evaporator, the expansion valve reduces the pressure and thereby reduces the boiling point below the temperature of the passenger compartment. Thus, heat transfers from the passenger compartment to the boiling refrigerant. In the condenser, the compressor raises the condensation point above the temperature of the outside air. Thus, the heat transfers from the condensing refrigerant to the outside air. The expansion valve and the compressor simply create pressure conditions that permit the laws of nature to function.

AIR CONDITIONER COMPONENTS

RECEIVER UNIT

The air conditioning system stores

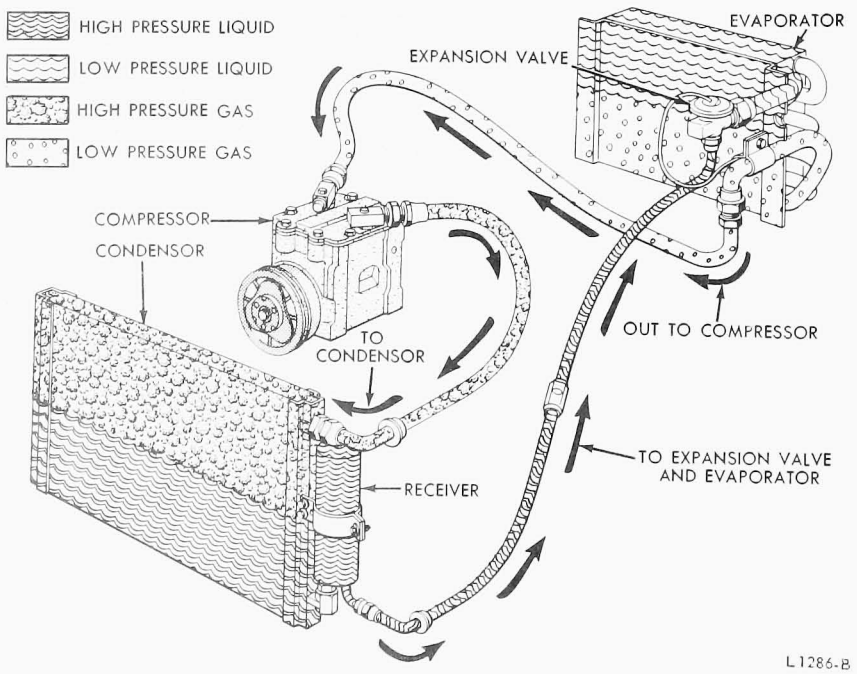

FIG. 1 Typical A/C Basic System

the liquid Refrigerant-12 under pressure in a combination receiver and dehydrator (Fig. 1). The pressure in the receiver normally varies from about 80 to 300 psi, depending on the surrounding air temperature and compressor speed.

The dehydrator serves the purpose of removing any traces of moisture that may have accumulated in the system. Even small amounts of moisture will cause an air cooling unit to malfunction. A fusible plug is screwed into the receiver. This will release the refrigerant before the refrigerant temperature exceeds 212 degrees F.

EVAPORATOR UNIT

When the cooling system is in operation, the liquid Refrigerant-12 flows from the combination receiver and dehydrator unit through a flexible hose to the evaporator (Fig. 1) where it is allowed to evaporate at a reduced pressure, to cool the evaporator. Air is blown through the evaporator fins and is thus cooled by the evaporator.

EXPANSION VALVE

The rate of refrigerant evaporation is controlled by an expansion valve (Fig. 1) which allows only enough refrigerant to flow into the evaporator to keep the evaporator operating efficiently, depending on its heat load.

The expansion valve on C-and W-Series Trucks consists of the valve and a temperature sensing capillary tube and bulb. The bulb is clamped to the outlet pipe of the evaporator. The expansion valve used on all except Cand W-Series is connected in line with both the inlet and outlet evaporator refrigerant lines. By use of internal passages leading to and from the underside of the valve diaphragm, the diaphragm senses the refrigerant temperature and pressure as it leaves the evaporator core. Thus the valve is controlled by evaporator outlet temperature.

The restricting effect of the expansion valve at the evaporator causes a low pressure on the low pressure side of the system of 12 to 50 psi, depending on the surrounding air temperature and compressor speed.

COMPRESSOR UNIT

The evaporated refrigerant leaving the evaporator (now in the form of a gas) at a pressure of 12 to 50 psi is pumped by the compressor, located on the engine (Fig. 2), into the top of the condenser.

The compressor maintains a pressure on its high pressure side of from 80 to 300 psi, depending on the surrounding air temperature and compressor speed.

CONDENSER

The air conditioning condenser is located in front of the radiator on light trucks and Econoline. On the C-, L-and W-Series, it is mounted on the cab roof. The condenser receives compressed (therefore heated) refrigerant gas from the compressor.

As the hot refrigerant gas flows down through the condenser, it is cooled by air passing between the sections of the condenser. The cooled, compressed refrigerant gas condenses to liquid refrigerant which then flows into the receiver.

LIQUID SIGHT GLASS

A liquid sight glass is mounted in the high pressure refrigerant line between the receiver and the expansion valve (Fig. 1). The sight glass is used to check whether there is enough liquid refrigerant in the system.

MAGNETIC CLUTCH

The compressor is cut in and out of operation by an electrically operated magnetic clutch mounted on the compressor crankshaft. The magnetic clutch is connected in series with the blower switch and the thermostatic de-icing switch.

THERMOSTATIC (DE-ICING) SWITCH

The thermostatic (de-icing) switch is controlled both manually and automatically. It is manually cut in or out of the clutch circuit by the temperature control lever or knob. With the temperature control in A/C position and the blower motor switch ON, the magnetic clutch is controlled through the automatic action of the switch. The temperature sensing tube of the switch is placed in contact with the evaporator fins. When the temperature of the evaporator becomes too cold, the switch opens the magnetic clutch electrical circuit, disconnecting the compressor from the engine. When the temperature of the evaporator rises, the thermostatic (de-icing) switch closes and energizes the magnetic clutch. This connects the compressor to the engine, and cooling action begins again.

When the blower switch is off or the temperature control lever or knob is **not in an A/C position, the magnetic clutch cannot be energized for compressor operation.**

SERVICE VALVES

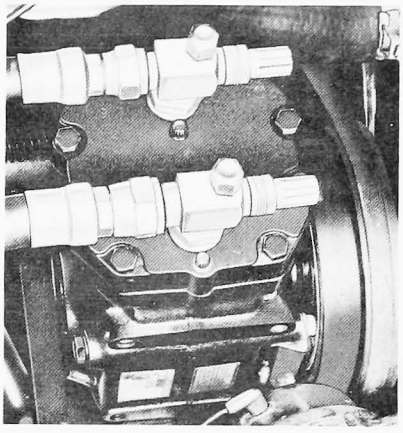
The service valves on the compressor are used to test and service the cooling system (Fig. 3). The high pressure service valve, mounted at the outlet to the compressor, allows access to the high pressure side of the system for attaching a service hose with attached pressure gauge.

The low pressure valve, mounted at the inlet to the compressor, allows access to the low pressure side of the system for attaching a service hose with attached pressure gauge.

Both service valves may be used to shut off the rest of the system from the compressor during compressor service.

HEATER-A/C SYSTEMS CONTROL DOORS

With all Ford heater-A/C systems, outside air comes through an opening at the upper cowl and into the right end of the evaporator and blower assembly. All evaporator and blower assemblies on all except Econoline and C-Series Trucks contain:



L1287-A

FIG. 2 Compressor Installed

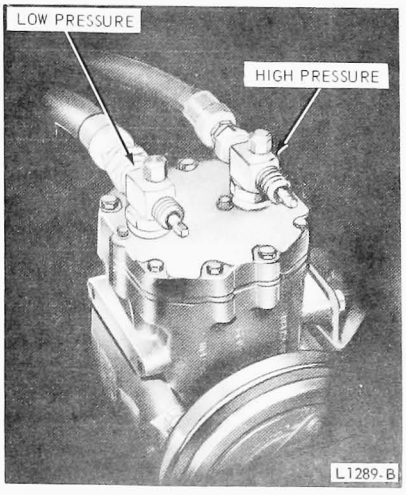


FIG. 3 Service Valves

1. An evaporator core through which flows Refrigerant-12.
2. A heater core through which flows engine coolant.
3. A blower which forces air through the evaporator core, through the heater core, and out through various outlets.
4. Several control doors.

The evaporator assembly on Econoline and C-Series Trucks does not contain a heater core, Item (2) above. For the separate heating systems, see Parts 36-20 and 23.

The control doors determine the following functions:

1. Whether outside air or inside (recirculating) air goes through the system.
2. The amount of air that goes through the heater core.
3. The particular outlet(s) through which the air discharges.

TESTING

SAFETY PRECAUTIONS

The refrigerant used in the air conditioner system is Refrigerant-12. Refrigerant-12 is non-explosive, non-inflammable, noncorrosive, has practically no odor, and is heavier than air. Although it is classified as a safe refrigerant, certain precautions must be observed to protect the parts involved and the person who is working on the unit.

Use only Refrigerant-12. Do not use refrigerant that was canned for pressure operated accessories (such as boat air horns). This type is not pure Refrigerant-12 and will cause a malfunction.

Liquid Refrigerant-12, at normal atmospheric pressures and temperatures, evaporates so quickly that it has the tendency to freeze anything it contacts. For this reason, **be very careful to prevent any liquid refrigerant from coming in contact with the skin and especially the eyes.**

Refrigerant-12 is readily absorbed by most types of oil. It is therefore recommended that a bottle of sterile mineral oil and a quantity of weak boric acid solution be kept nearby when servicing the air conditioning system. **Should any liquid refrigerant get into the eyes, immediately use a few drops of mineral oil to wash them out, then wash the eyes clean with the weak boric acid solution. Seek a doctor's aid immediately even though irritation may have ceased.**

Always wear safety goggles when servicing any part of the refrigerant system.

The Refrigerant-12 in the system is always under pressure. Because the system is tightly sealed, heat applied to any part would cause this pressure to build up excessively.

To avoid a dangerous explosion, never weld, use a blow torch, solder, steam clean, bake body finishes, or use any excessive amount of heat on or in the immediate area of any part of the air cooling system or refrigerant supply tank, while they are closed to the atmosphere whether filled with refrigerant or not.

The liquid refrigerant evaporates so rapidly that the resulting refrigerant gas will displace the air surrounding the area where the refrigerant is released. To prevent possible suffocation in enclosed areas, always discharge tthe refrigerant from an air cooling system into the garage exhaust collector. Always maintain good ventilation surrounding the work area.

Although Refrigerant-12 gas, under normal conditions, is nonpoisonous, the discharge of refrigerant gas near an open flame can produce a very poisonous gas. This gas will also attack all bright metal surfaces. This poisonous gas is generated when the flame-type leak detector is used. **Avoid inhaling the fums from the leak detector. Make certain that Refrigerant-12 is both stored and installed in accordance with all state and local ordinances.**

When admitting Refrigerant-12 gas into the cooling unit, always keep the tank in an upright position. If the tank is on its side or upside down, liquid Refrigerant-12 will enter the system and damage the compressor. In surrounding air temperatures above 90 degrees F, prolonged engine idle will result in excessively high compressor pressures.

VISUAL INSPECTION

Obstructed air passages, broken belts, disconnected or broken wires, loose clutch, loose or broken mounting brackets may be determined by visual inspection of the parts.

PROPER USE OF SERVICE VALVES

The service valves (Fig. 4) are used throughout the service procedures in this section and in the following, Adjustments.

When in the **Back-Seated** position, both valves are cut off from the gauge manifold; the low pressure valve is open between the suction side of the compressor and the evaporator; and the high pressure valve is open between the discharge side of the compressor and the condenser. This is the normal operating position.

In the **Front-Seated** position, the low pressure valve cuts off the suction side of the compressor from the evaporator; and the high pressure valve cuts off the discharge side of the compressor from the condenser.

In the **Mid-Position,** the valves are open between the gauge manifold, the cooling system, and the compressor. This is the position used in performing various tests and service operations.

COMPRESSOR TEST

1. Attach the manifold gauge set (Fig. 5). It will not be necessary to attach the Refrigerant-12 tank or the vacuum pump.
2. Set both manifold gauge valves at full clockwise (closed) position.
3. Turn the low pressure service valve to the Front-Seated (full clockwise) position, and turn the high pressure service valve to the Back-Seated (full counterclockwise) position (Fig. 4).
4. With the engine running at idle speed, set the A/C controls to maximum cooling (to engage the compressor clutch) **for 30 seconds only. Then, to avoid damaging the compressor, quickly disengage the clutch by returning the A/C controls to OFF**

The low pressure (suction) gauge should reach 20-inches of vacuum within the 30 seconds of operation and should remain below zero psi for at least one minute.

If the compressor does not satisfy these two conditions after at least 3 cycles of clutch engagement, the compressor has either a blown head gasket or leaking valves. Remove the

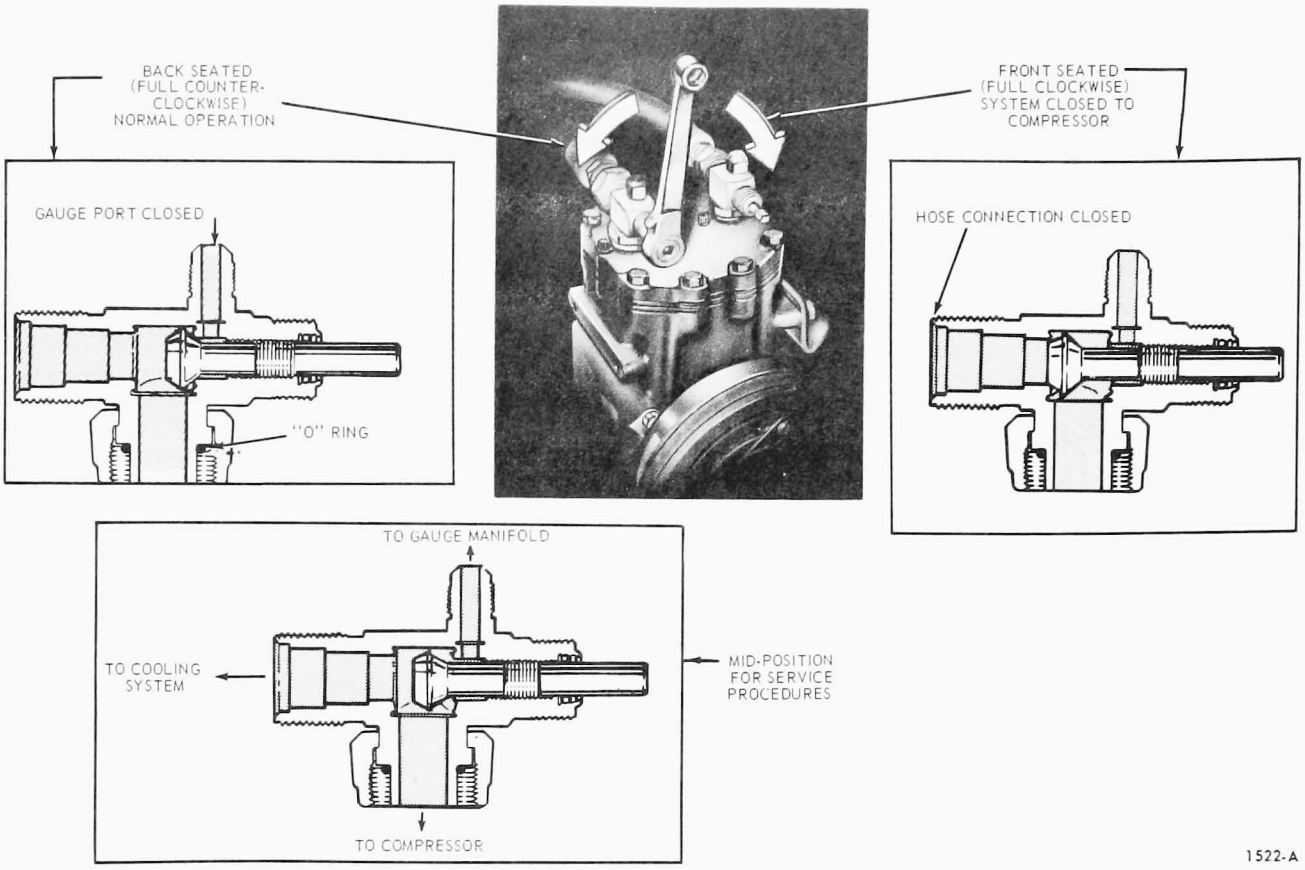

FIG. 4 Service Valve Positions

head and inspect the valve plate and gaskets for damage. Replace parts if necessary. Replace a compressor, if the cylinder walls are scored or pieces of metal are inbedded in the pistons.

CHECKING FOR LEAKS

Attach the manifold gauge set (Fig. 5). Leave both manifold gauge valves at the maximum clockwise position. Set both service valves at the center position. Both gauges should show approximately 60 to 80 pounds pressure at 75 degrees F with the engine not running. If very little or no pressure is indicated, leave the vacuum pump valve closed, open the Refrigerant-12 tank valve, and set the low pressure (suction) manifold gauge valve to the counterclockwise position. This opens the system to tank pressure. Check all connections, and the compressor head gasket, oil filler plug, and shaft seal for leaks, using a flame-type leak detector (Fig. 6). **Avoid inhaling the fumes from the leak detector.** Follow the directions with the leak detector. The smaller the flame the more sensitive it is to leaks.

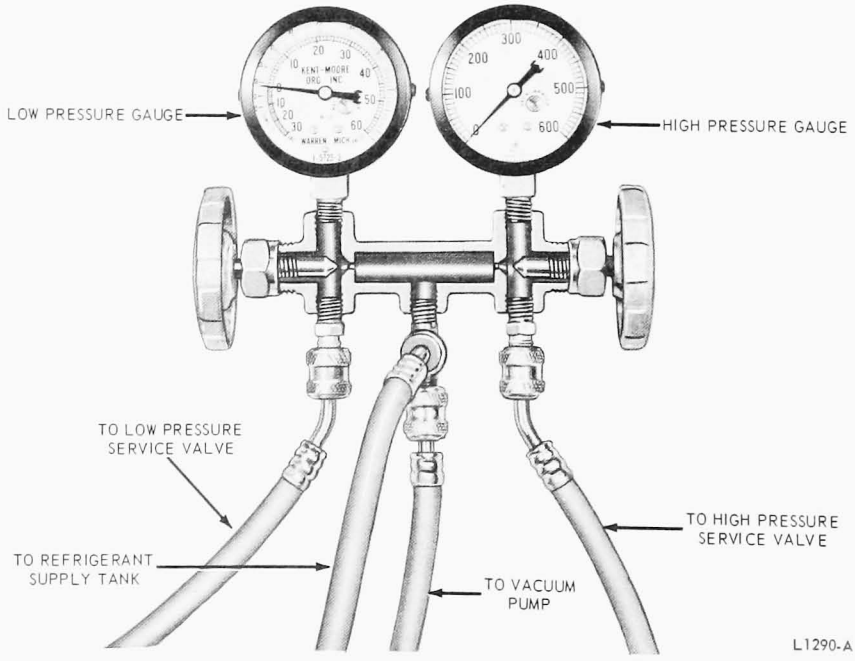

FIG. 5 Manifold Gauge Set

Therefore, to insure accurate leak indication keep the flame as small as possible. The copper element must be red hot. If it is burned away, replace the element. Hold the open end of the hose below each suspected leak point for two or three seconds. The flame will normally be almost colorless. The slightest leak will be indicated by a bright green blue color to the flame. Be sure to check the manifold gauge set and hoses for leaks as well as the rest of the system.

If the surrounding air is contaminated with refrigerant gas, the leak detector will indicate this gas all the time. Good ventilation is necessary to prevent this situation. A fan, even in a well ventilated area, is very helpful in removing small traces of refrigerant vapor.

USE OF SIGHT GLASS

Clean the sight glass before checking for a proper charge of refrigerant. Then, observe the sight glass for bubbles with the engine running at 1500 rpm and the A/C controls set at maximum cooling. A continuous or large amount of bubbles in the sight glass indicate an undercharge of refrigerant. If an undercharge of refrigerant is found, check the system for leaks. Repair any leaks, evacuate the system with a good vacuum pump, and charge the system with the proper amount of Refrigerant-12.

No bubbles in the sight glass immediately after clutch engagement indicate either too much refrigerant or a complete loss of refrigerant. While observing the sight glass, cycle the magnetic clutch off and on, with the engine running at 1500 rpm. If refrigerant is in the system, bubbles will appear while the clutch is off and disappear when the clutch is on. If no bubbles appear during the on and off cycle of the magnetic clutch, there is no refrigerant in the system. If there is no refrigerant in the system, it will be necessary to leak test, repair as required, and charge the system. **Under conditions of extremely high temperatures, occasional foam or bubbles may appear in the sight glass.**

AIR CONDITIONER PERFORMANCE TEST

The pressures developed on the high pressure (discharge) and low pressure (suction) side of the compressor indicate whether or not the system is operating properly.

Attach the manifold gauge set (Fig. 5). It will not be necessary to attach the Refrigerant-12 tank. Set both manifold gauge valves at the maximum clockwise, or closed, position. Set both service valves at the center position.

Check the system pressures with the engine running at 1500 rpm, all controls set for maximum cooling, and the front of the vehicle at least 5 feet from any wall.

The actual pressures indicated on the gauges will depend on the temperature of the surrounding air and the humidity. Higher air temperatures along with high humidity, will give higher system pressures.

At idle speed and a surrounding air temperature of 100 to 110 degrees F, the high pressure may go as high as 300 pounds or more. If it becomes necessary to operate the air conditioner under these conditions, keep the high pressure down with a fan directed at the condenser and radiator.

Correct pressures for a normally operating system are shown on line (1) in the Refrigerant System Analysis Chart (Fig. 7): the low pressure gauge should indicate 10 to 20 psi; the high pressure gauge should indicate 180 to 225 psi. Lines 2 through 8 in Fig. 7 show various abnormal pressure conditions and the possible problems that could be their cause.

THERMOSTATIC DE-ICING SWITCH TEST

Fill a container with crushed ice, salt and water. Put enough salt in the water so that the temperature of the solution is 25 degrees F or lower.

Use a self-powered test light or ohmmeter connected to the switch terminals to check whether or not the switch is closed.

Place the sensing tube in the ice, salt and water solution. **Make certain that no salt water gets into the control.** The thermostatic (de-icing) switch contact points should open and remain open while the tube is in the solution. Remove the sensing tube from the solution. As the tube warms up, the switch contacts should close. If the switch contacts do not open and close as indicated, replace the switch.

An ohmmeter check of the contacts should show a resistance of less than an ohm. If a resistance of one ohm or more occurs, replace the switch.

RECEIVER—DRYER TEST

Operate the air conditioner for about five minutes; then, slowly move your hand across the length of the unit from one end to the other. There should be no noticeable difference in temperature. If cold spots are felt, it indicates that the unit is restricting the refrigerant flow, and the receiver-dryer must be replaced.

MAGNETIC CLUTCH TEST

Disconnect the magnetic clutch wire at the bullet connector, and connect it to the negative lead of an ammeter. Connect the positive lead of the ammeter to the battery positive terminal. The magnetic clutch should pull in with a distinct click and the current reading on the ammeter should be to specification.

BLOWER MOTOR TEST

Disconnect the blower motor wire at the bullet connector, and connect it to the negative lead of an ammeter. Connect the positive lead of the ammeter to the battery positive terminal. The motor should operate and the reading on the ammeter should be to specification.

COMPRESSOR CRANKSHAFT SEAL LEAK TEST

The cross sectional view in Fig. 8 shows the design and the components of the seal assembly. Oil leak problems can

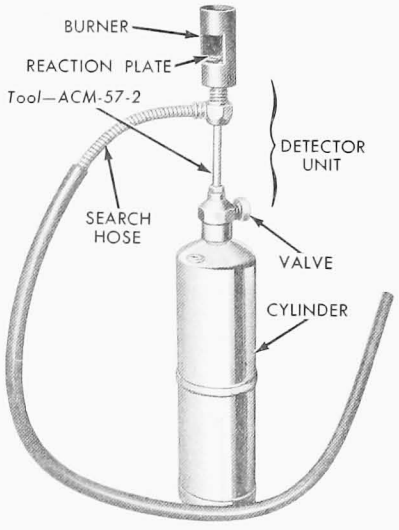

FIG. 6 Torch Type Leak Detector

Low Press (Suction) Gauge	High Press (Discharge) Gauge	Problem
(1) 10-20 psi	180-225 psi	Normal
(2) Normal	Too High	Restriction in line. Plugged Condenser { Look for frost ring. Radiator Overheating. Air in System. Engine fan too small – or Viscous fan (Fluid Clutch) Inoperative. Condenser Blower Not Operating (Trucks Only).
(3) Too High	Too High	Condenser Blower Not Operating (Trucks Only). Very hot shop, no auxiliary fan directed toward condenser. Restricted air flow through condenser. Overcharged system.

Low Press (Suction) Gauge	High Press Discharge) Gauge	Problem
(4) Too High	Too Low	Compressor head gasket blown.
(5) Too Low	Too Low	Undercharged system.
(6) Vacuum	Normal	Expansion valve stuck closed. Plugged receiver (see Note). Iced up (Moisture in System).
(7) Too High	Normal	Capillary tube temperature sensing bulb uncovered and exposed to engine compartment heat.
(8) Normal (Complaint of Intermittent cooling)	Normal	Moisture in system, passes critical point and clears up but freezes again.
NOTE: If the condenser is hot from top to bottom and the receiver is hot but the receiver outlet line is cool, the receiver desiccant is restricted. Replace the receiver.		

CL 1521-A

FIG. 7 Refrigerant System Analysis Chart

be identified by observing the three possible leakage paths shown in Fig. 9.

OIL LEAKAGE PAST CARBON RING

Oil weepage through the carbon ring forming a streak or drip pattern as shown in the left illustration of Fig. 9 is considered normal. However, if oil is present on the surface of the compressor beyond the clutch or has sprayed on the hood and surrounding brackets, the leakage is excessive. Replace the seal assembly.

OIL LEAKAGE THROUGH O-RING

Leakage through the O-ring type gasket on the cover plate (center illustration, Fig. 9) indicates possible cracked, pinched, split or loose mounting screws. Check the screws for good condition and proper torque (7 to 13 ft-lbs). If there is heavy oil discharge with screws of good condition and correct torque, replace the oil seal assembly.

OIL LEAKAGE THROUGH DAMAGED BELLOWS

Oil will leak through the rubber bellows as shown in the right illustration of Fig. 9, if the bellows distorts or cracks due to heat, a large discharge of oil on the front of the compressor beyond the clutch indicates this type of leakage. Replace the oil seal assembly.

REFRIGERANT 12 LEAKAGE

Refrigerant 12 leakage through any part of the seal can be determined only by a leak detector. **Avoid inhaling the fumes from the leak detector.** Be sure to wipe all the oil away from the seal area before using the leak detector, because

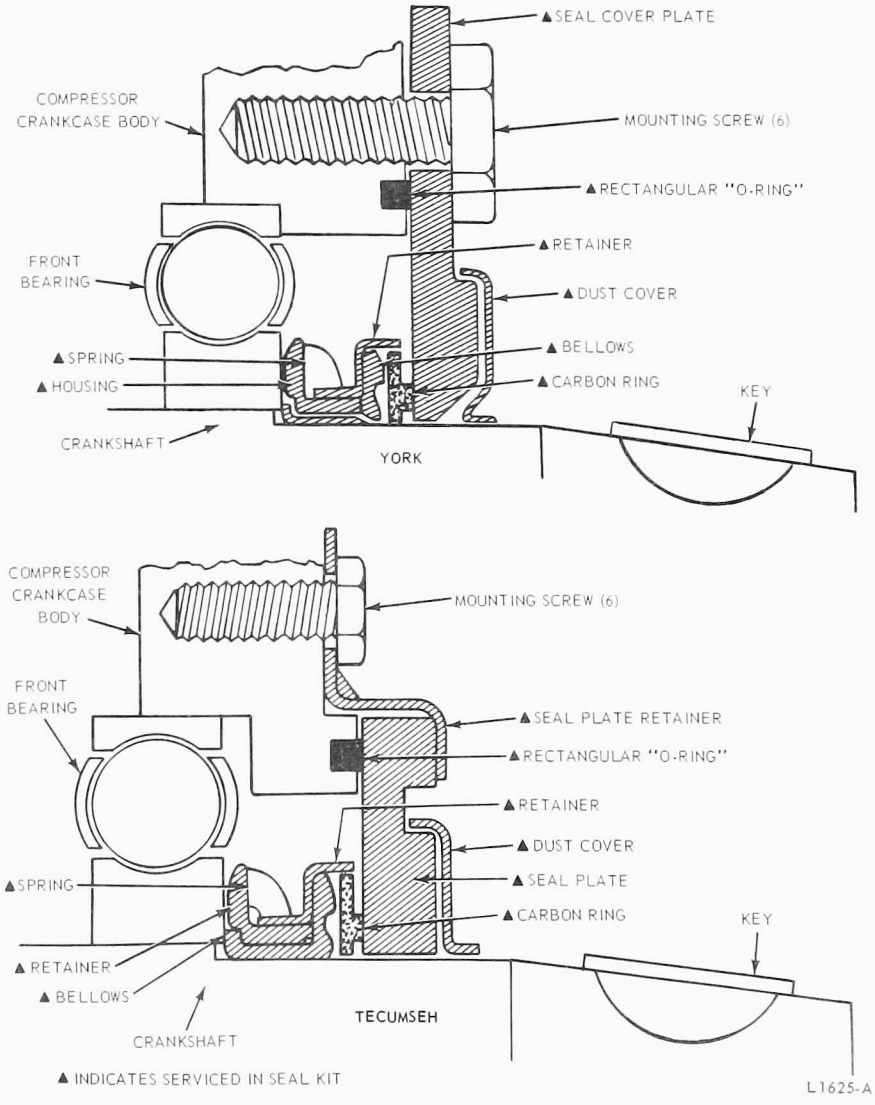

FIG. 8 Compressor Oil Seal—Cross Sectional View

the oil may contain refrigerant which would give erroneous readings. If refrigerant leakage at the seal exceeds 1 oz. per year, replace the seal as outlined in Disassembly and Assembly.

If no leak is found at the compressor crankshaft seal, thoroughly check all system fittings and lines for leaks as outlined in this Section.

ADJUSTMENTS

DISCHARGING THE SYSTEM

Discharge the refrigerant from the system before replacing any part of the system, except the compressor.

To discharge the system, connect the manifold gauge set to the system (Fig. 5). Do not connect the manifold center connection hoses to the Refrigerant-12 tank or to the vacuum pump. Place the open end of these hoses in a garage exhaust outlet. Set both manifold gauge valves at the maximum counterclockwise or open position. Open both service valves a slight amount (Fig. 3) and allow the refrigerant to discharge slowly from the system.

Do not allow the refrigerant to rush out, because it will carry the compressor oil out with it.

EVACUATING THE SYSTEM

Attach the manifold gauge set, a tank of Refrigerant-12 and a vacuum pump to the system (Fig. 5). The refrigerant 12 tank should be set on a scale and its weight noted so that the proper amount of refrigerant will enter the system during charging. Make certain that the Refrigerant-12 tank valve is tightly closed. Set both service valves to the mid-position (Fig. 4). Open both manifold valves (Fig. 5). To release any pressure remaining in the system after discharging, loosen a hose connection. Then retighten all connections. Open the vacuum pump valve and run the pump until the low pressure gauge reads at least 25-inches, and as close to 30 inches of vacuum as possible. Continue vacuum pump operation for 20 to 30 minutes to boil any moisture out of the system. Close the pump valve. Turn off the pump.

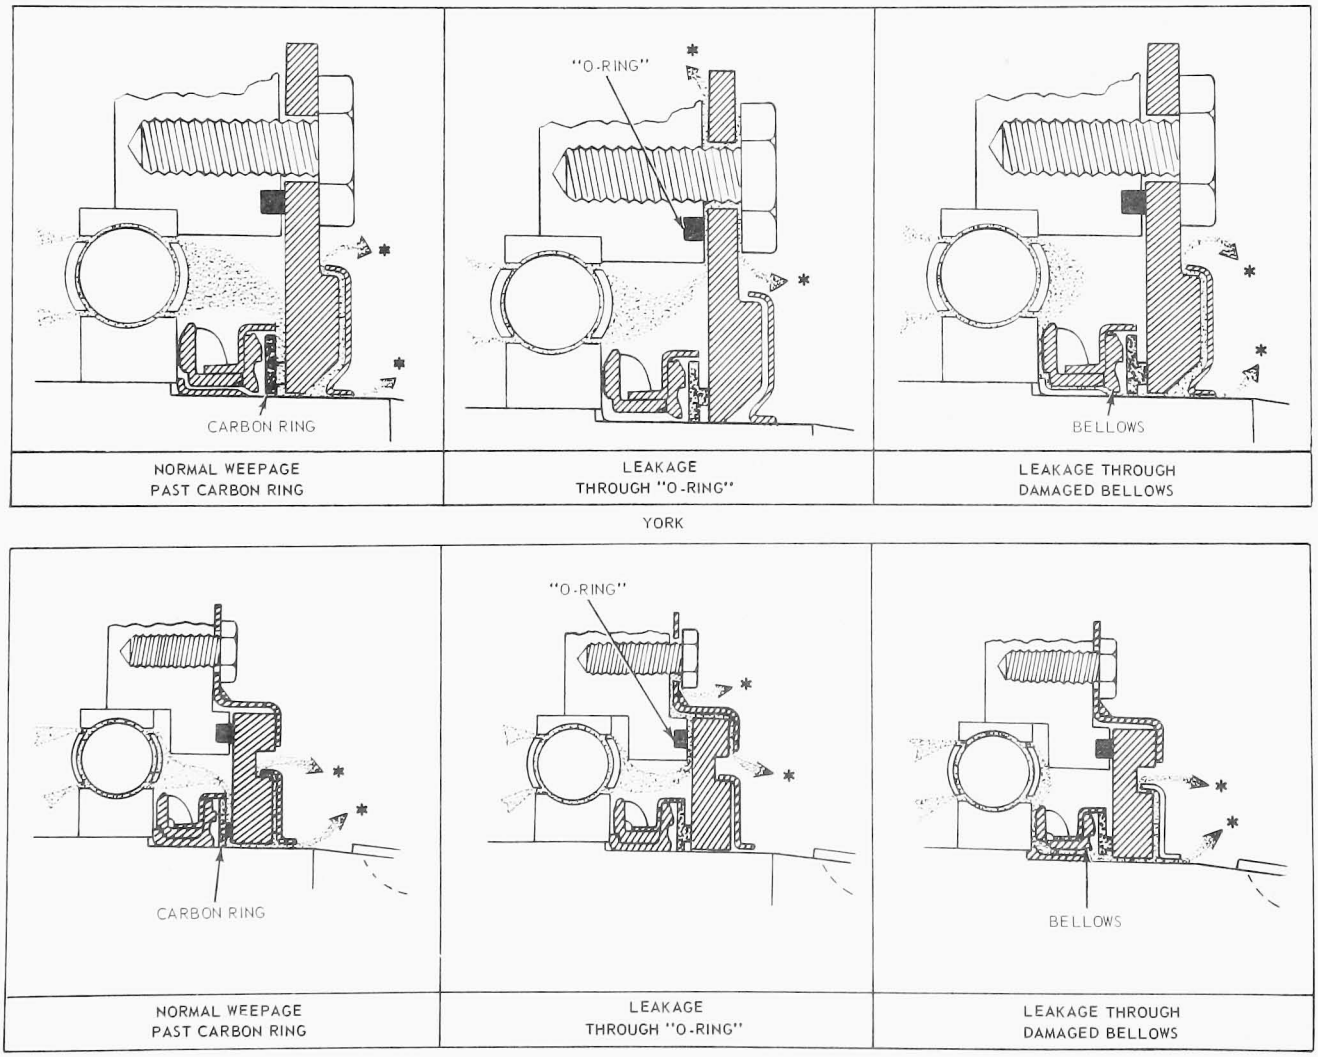

FIG. 9 Oil Leakage Paths—Compressor Oil Seal

CHARGING THE SYSTEM

1. Evacuate the system as outlined in the foregoing procedure.

Be sure to subtract the specified charge from the weight of the tank as registered on the scale so that you will know when to stop charging. For example, if the scale shows a total weight of 8 pounds and the specified charge is 2 1/2 pounds, you should stop charging when the scale shows 5 1/2 pounds.

2. Leave both service valves at the mid-position (Fig. 10) and the vacuum pump valve closed.
3. Leave the low pressure (suction) manifold gauge valve at the full counterclockwise or open position (Fig. 5).
4. **Set the high pressure (discharge) manifold gauge valve at the full clockwise or closed position.**
5. Open the Refrigerant-12 tank valve to allow refrigerant to enter the system, and observe the gauges. When both gauges reach 60 to 80 pounds at approximately 75 degrees F, shut off the tank valve.
6. Perform the leak test with the leak detector as outlined in Testing in this Part.
7. Set the temperature control at the maximum COLD position, the mode control at the PANEL position and set the blower switch at HI speed.
8. Start the engine, and open the R-12 tank valve again to prevent drawing vacuum on the suction side. When the suction gauge shows pressure instead of vacuum, close the R-12 tank valve.
9. Run the engine at 1500 rpm for about ten minutes or until both gauge readings have stabilized. If the clutch disengages during the stabilization process, continue running the engine until the pressures again stabilize after the clutch re-engages.
10. With the engine still running, open the R-12 tank and charge the system until the scale indicates that the specified weight of R-12 refrigerant has entered the system. Then close the valve.
11. If the refrigerant will not enter the system due to low temperature, it may be necessary to place the Refrigerant-12 tank in a container of hot water at about 150 degrees F. This will increase the R-12 pressure and force the gas from the tank during charging. **Never heat the Refrigerant-12 tank with a torch. A dangerous explosion may result.**

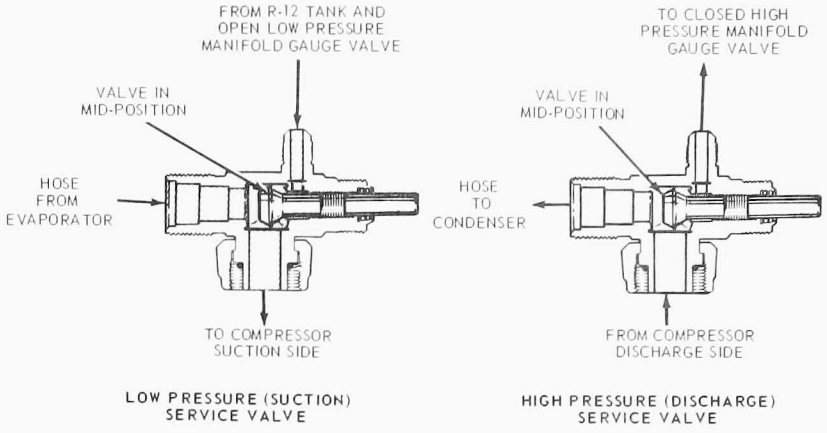

FIG. 10 Charging the Air Conditioning System

12. During the charging, the high pressure (discharge) side may build up to an excessive value. This can be caused by an overcharge of refrigerant, or an overheated engine, in combination with high surrounding temperatures. Never allow the high pressure to exceed 240 pounds while charging. Stop the engine, determine the cause, and correct it.
13. After the proper charge has been made, close the Refrigerant-12 tank valve, and check the system pressures for proper operation as described under Air Conditioner Performance Test, Testing in this Part.
14. After satisfactory operation has been achieved, set both service valves at the maximum counterclockwise (gauge port closed) position (Fig. 4). Remove the gauge set, and cap the service valve gauge ports and valve stems.

CHARGING FROM SMALL CONTAINERS

Refrigerant-12 is available in one-pound cans. **Do not open the high pressure (discharge) gauge valve on the manifold because the container can explode.**

1. A special valve and valve retainer is required for connecting the small can to the A/C system. Attach the valve retainer to the can by engaging the three tabs of the retainer to the lip at the top of the can. Turn the valve assembly into the threaded hole in the center of the valve retainer. In containers where the center of the can is deeply recessed, a washer should be inserted before installing the valve.

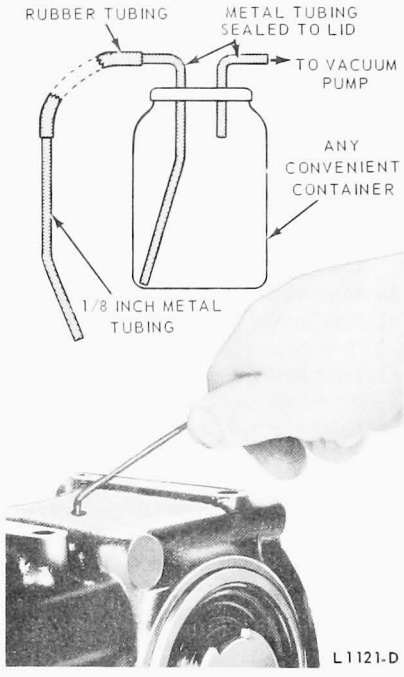

FIG. 11 Compressor Oil Level Check and Oil Trap

2. Connect the manifold gauge set to the system (Fig. 6). Connect the hose (normally connected to the large R-12 tank) to the special valve on the small can. **Make sure that the valve is closed (full clockwise position).**
3. Once the can is connected, charge the system as outlined in the foregoing procedure. When the can is empty, close the valve and remove the empty can. Connect a new can, open the valve again and continue charging until the specified weight of R-12 has entered the system.

When you need a half pound of refrigerant such as with a 2 1/2 pound charge capacity, stop charging from one

can when extreme cold is felt half-way down the can. Weigh the can to make sure one-half pound of refrigerant is installed.

COMPRESSOR OIL LEVEL CHECK

Under normal conditions, when the air conditioning system is operating satisfactorily, the compressor oil level need not be checked. There is no place for the oil to go except inside the sealed system. When the engine is first started, some of the oil will be pumped into the rest of the refrigerant system. After several minutes of operation, most of the oil is returned to the compressor crankcase.

Check the compressor oil level only if any portion of the refrigerant system is being replaced, or if there was a leak in the system and the refrigerant is being replaced.

1. After the system has been charged, operate the system for about ten minutes or until the pressures have been stabilized in a surrounding temperature of 60 degrees or above.
2. Stop the engine and isolate the compressor as outlined in the following procedure, Isolating the Compressor.
3. Remove the oil filler plug from the compressor. Insert a flattened 1/8-inch diameter rod (Fig. 11) in the oil filler hole until it bottoms. The rod or dipstick fashioned for the particular compressor (Figs. 12 and 13) should be used. **The dipstick must be wiped completely clean before insertion.** If necessary, **slightly** rotate the compressor crankshaft by hand so that the dipstick will clear the crankshaft.

On horizontally mounted compressors, the oil check hole is located on the side of the crankcase that faces up. On the opposite or downward side, there is a corresponding boss provided on the inner wall as an alternate oil check hole for a different mounting. When checking the oil level on such a compressor, angle the dipstick so that it bottoms against the lower side of the crankcase and not against the boss.

4. Pull out the dipstick, and check the oil indication. It should show at least the minimum amount of oil as indicated in Figs. 12 and 13.

If the oil level is low, add ESA-M2C31-A (Ford Part No. C9AZ-19577-A) oil.

If too much oil is indicated proceed as follows:

a. Draw out all of the oil using a trap similar to that shown in Fig. 11, or remove the compressor from the vehicle and pour the oil out of the crankcase.

b. Add approximately 4 oz. of oil to the crankcase, and replace the filler plug. Reinstall the compressor, if it was removed.

5. Evacuate the compressor with the vacuum pump (both service valves front-seated (Fig. 4) and both manifold gauge valves open).
6. Connect the compressor back into the system by turning both service valves to the back-seated (full counterclockwise) position.
7. Operate the system again for another 10 minutes as in Step 1,-and recheck the oil level as in Steps 3 and 4.

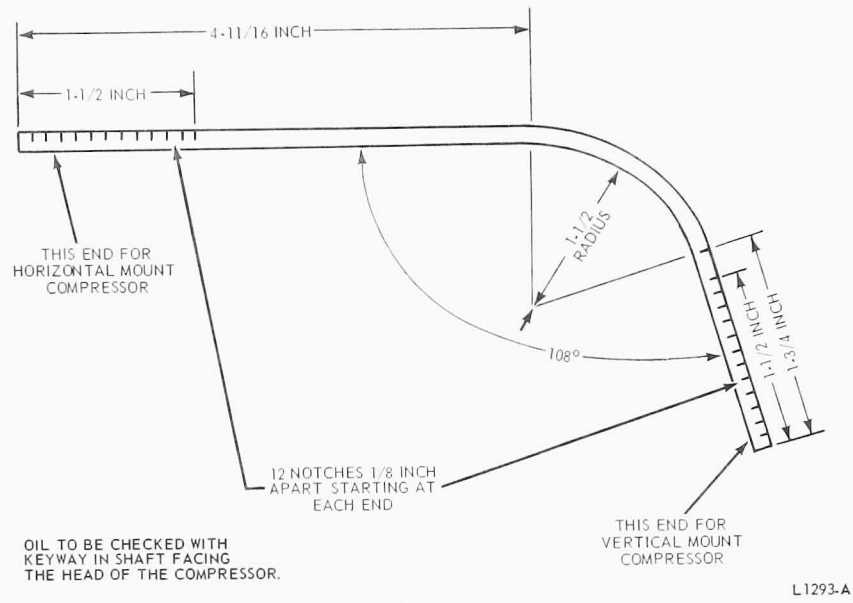

FIG. 12 York Compressor Oil Level Dipstick

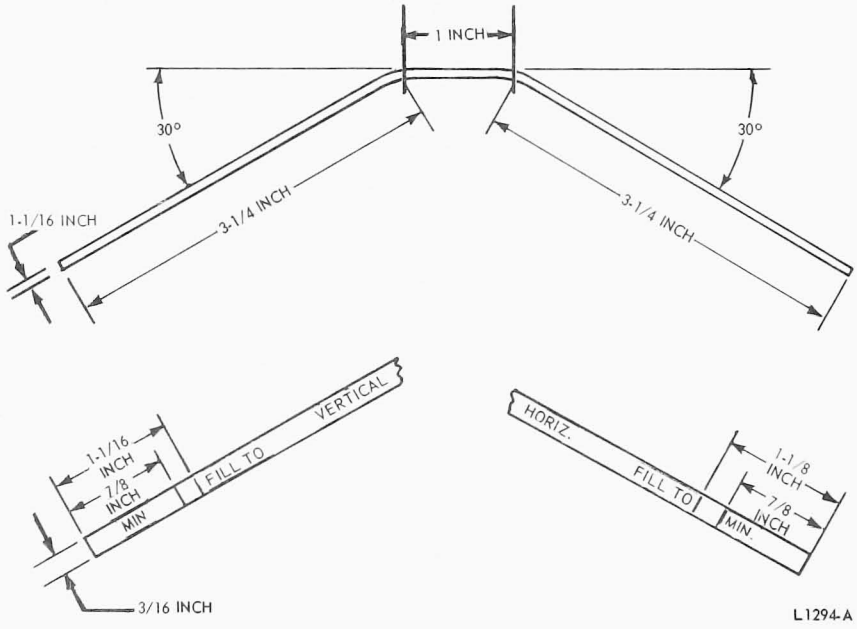

FIG. 13 Tecumseh Compressor Oil Level Dipstick

8. Replace the oil filler plug. Evacuate and connect the compressor back into the system.
9. Operate the system again for five minutes and make a final oil level check.

It is necessary to recheck the oil level a second time to be sure that all the oil has returned to the compressor.

10. Replace the oil filler plug. Evacuate and connect the compressor back into the system.
11. Check the compressor filler plug area for leaks with a leak detector.

ISOLATING THE COMPRESSOR

This procedure is used when checking the compressor oil level and when it is desired to replace the compressor without losing the refrigerant charge.

To isolate the compressor from the system, turn both the high and the low pressure service valves to the extreme clockwise (frontseat) position (Fig. 4). Loosen the cap on the high pressure service valve gauge port, and allow the gas to escape until the compressor is relieved of refrigerant pressure.

Loosen the cap a small amount only, and do not remove it until the pressure is completely relieved.

To connect the compressor back into the system, evacuate the compressor with a vacuum pump at both service valve gauge ports, close the vacuum pump valve, turn both service valves to the maximum counterclockwise (back-seat) position, and cap the high pressure service valve gauge port and service valve stems.

REMOVAL AND INSTALLATION

COMPRESSOR—ALL EXCEPT ECONOLINE

All compressor removal and installation operations, except belt replacement, can be performed only after the unit has been isolated from the rest of the system. (See Adjustments, in this part).

To reduce the amount of time to make a compressor replacement, the service compressors are dehydrated and filled with refrigerant (R-12) and the proper amount of the specified refrigerant oil is in the crankcase when received.

When replacing a compressor, the oil level in the old compressor should be checked. Then the right amount of oil should be removed from the new compressor so that the level in the new compressor is the same as that in the old compressor. This keeps the amount of oil in the system a constant. Failure to use this procedure is the most common reason for excessive oil in the crankcase. Refer to Compressor Oil Level Check, Adjustments in this part.

Removal

1. Isolate the compressor. Refer to Adjustments in this Part, and disconnect the two service valves and hoses from the compressor (Fig. 14). Energize the clutch and loosen and remove the clutch mounting bolt.
2. Install a 5/8-11 bolt in the clutch drive shaft hole. With the clutch still energized, tighten the bolt to loosen the clutch from the shaft. Disconnect the clutch wire at the bullet connector.
3. Loosen the idler pulley or alterntor and remove the drive belt and the clutch and then remove the mounting bolts and the compressor.

Installation

Before installing the compressor, carefully remove any burrs or dirt that may be on the compressor shaft. The shaft must be dry and brightly polished.

1. Mount the clutch on the shaft and install the mounting screw and washer finger-tight. Place the compressor on the mounting bracket and install the four mounting bolts finger-tight.
2. Connect the clutch wire, energize the clutch and torque the clutch mounting bolt to specification. Tighten the compressor mounting bolts to specifications.
3. Install the belt and adjust and tighten the idler pulley.
4. Install the service valves on the compressor using new seals. **Be certain to remove the rubber shipping plugs first.** Tighten the service valve nuts to specification. Do not over tighten. The new ROTOLOK service valves can be rotated slightly on their seat without breaking the high pressure seal. This is not an indication of a loose valve. Leak test the compressor, then evacuate it and connect it back into the system.
5. Check the oil level in the compressor, and add or remove oil if necessary (Adjustments).

COMPRESSOR—ECONOLINE

Removal

1. Remove the engine cover and remove the air cleaner.
2. If the vehicle is equipped with an auxiliary heater, partially drain the cooling system.
3. Remove the oil filler tube.
4. Insulate the compressor (Adjustments), and disconnect the two service valves and hoses from the compressor. Cover the opening, to prevent dirt from entering the system. Energize the clutch and remove the clutch mounting bolt.
5. Install a 5/8-11 bolt in the clutch drive shaft hole. With the clutch still energized, tighten the bolt to loosen the clutch from the shaft. Remove the clutch pulley and bolt. Disconnect the clutch wire at the connector. Remove the brush holder from the shaft.
6. If the vehicle is equipped with an auxiliary heater, disconnect the heater hoses at the water valve and at the T connector in the line.
7. On V-8 models, remove the hose retaining bracket from the engine and position the hoses out of the way.
8. Remove the compressor-to-engine bracket bolts.
9. Remove the compressor mounting bolts. On V-8 models, the compressor has 6 mounting bolts. Two bolts are removed from the front of the vehicle and 4 bolts are

removed from under the vehicle. On 6-cylinder models, the compressor has 4 mounting bolts. The 2 rear mounting bolts are reached from under the vehicle. On 6-cylinder models, move the compressor outboard and remove the 3 front bracket mounting bolts.

10. Lift the compressor from the vehicle.

Installation

1. Install the clutch brush holder on the front of the compressor and connect the wire.
2. Position compressor to the mounting brackets. On V-8 models, install the 6 mounting bolts. On 6-cylinder models, install the front bracket mounting bolt, and then install the four mounting bolts.
3. Install the compressor-to-engine mounting brackets.
4. On V-8 models, position the hoses in the retaining bracket and install the bracket on the engine.
5. Install both heater hoses if they were disconnected.
6. Install the clutch assembly on the shaft. Then install the retaining bolt. Energize the clutch and torque the retaining bolt to specification.
7. Position the clutch pulley drive belt and adjust the belt tension.
8. Install the oil filler tube.
9. Install the service valves on the compressor using new gaskets. Tighten the service valve flared nuts to specification. **Do not overtighten the flared nuts. The service valves can be rotated slightly without breaking the high pressure seal. This is not an indication of a loose valve.**
10. Leak test the compressor, then evacuate it and connect it back into the system.
11. Operate the system on full air conditioning for 15 minutes. Then isolate the compressor and check the oil level in the compressor and add or remove oil as required.
12. Add coolant to the radiator as required.
13. Install the air cleaner.
14. Install the engine cover.

VALVE PLATE AND HEAD GASKET

The procedure for replacing a blown head gasket is identical to the procedure for replacing the valve plate except that the old valve plate is used. If a worn or damaged valve plate has caused the cylinder walls to become scored or has inbedded pieces of metal in the pistons, the compressor should be replaced.

Removal—All Compressors

1. Isolate the compressor (Adjustments in this part), and disconnect both service valves. Place a clean drip pan under the horizontally mounted compressor.
2. Remove the cylinder head bolts.
3. Remove the valve plate and cylinder head from the compressor by tapping upward with a fiber hammer on the overhanging edge of the valve plate.
4. Remove the valve plate from the cylinder head by holding the head and tapping against the valve plate.
5. Remove the drip pan from under the horizontally mounted compressor. Then, remove all particles of gasket, dirt and foreign material from the surface of the cylinder head and

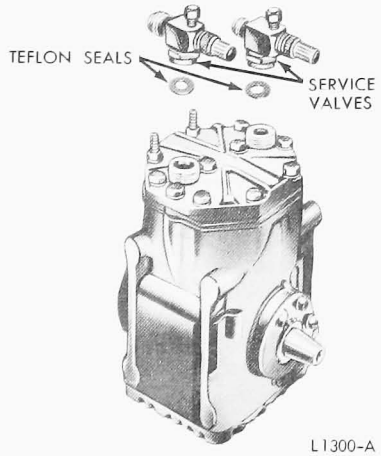

FIG. 14 Compressor Service Valves Removed

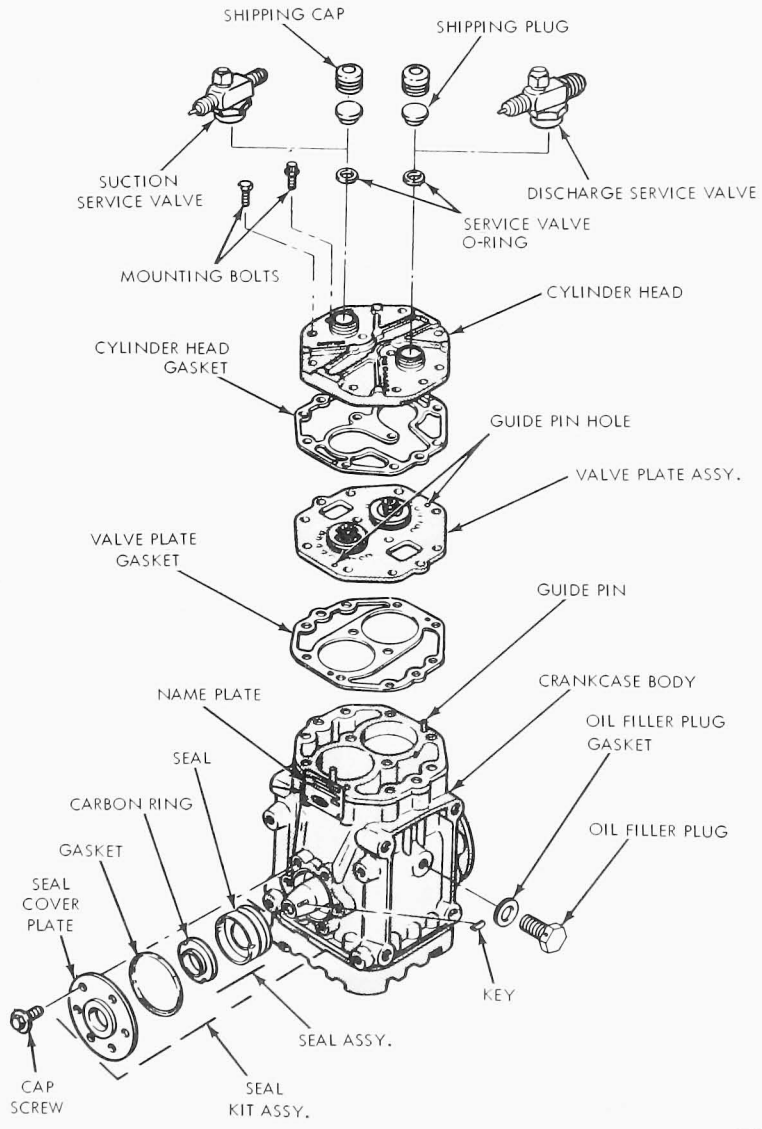

FIG. 15 York Compressor—Disassembled

cylinder face. **Be very careful not to scratch or nick the mating surfaces or any edges.**

Installation (York Compressor—Fig. 15)

1. Apply a thin film of clean refrigeration oil to each side of the valve plate gasket (Fig. 15).
2. Place the new valve plate gasket in position on the crankcase so that the crankcase dowel pins go through the dowel pin holes in the gasket (Fig. 15).
3. Place the valve plate in position on the cylinder so that the dowel pins go through the dowel pin holes (Fig. 15).
4. Apply a light film of clean refrigeration oil on each side of the cylinder head gasket. Then, place the gasket and cylinder head on the cylinder with the dowel pins inserted into the dowel pin holes in the gasket and head.
5. Insert the two longer cap screws in the two center holes of the cylinder head. Then, insert the remaining cap screws in the holes around the edge of the cylinder head. The four 12 point head screws should be inserted into the four holes closest to the service ports.
6. Tighten all head cap screws until they contact the head. Then, torque the two center screws to 15-23 ft-lbs.
7. Tighten the remaining cap screws in a pattern so that the cap screws diagonally opposite each other are evenly tightened to 15-23 ft-lbs. After the cylinder head has been installed 1/2 hour, retorque the head bolts to 15-23 ft-lbs.
8. Inspect the top of the cylinder head service valve ports to be sure that they are free of nicks and imperfections. Connect the service valves with new O-rings to the correct compressor ports and torque to specification. Then, check the compressor oil level and add or remove oil as required. (See Compressor Oil Level Check in Adjustments). Evacuate the compressor and connect it back into the system.

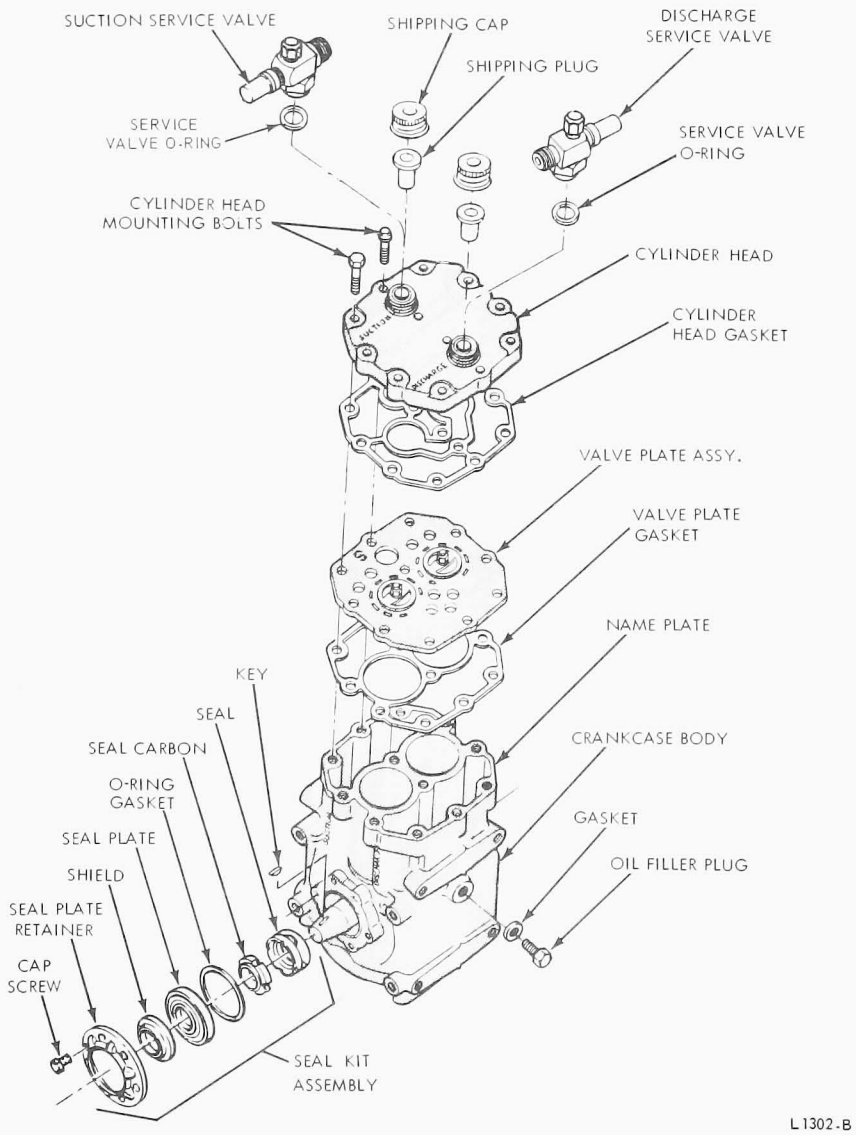

FIG. 16 Tecumseh Compressor—Disassembled

Installation (Tecumseh Compressor—Fig. 16)

1. Apply a thin film of clean refrigeration oil to each side of the valve plate gasket (Fig. 16).
2. Place the new valve plate gasket on the crankcase cylinder face and align the bolt holes.
3. Place the valve plate on the valve plate gasket so that the letter S (stamped on the valve plate) is on the same side of the crankcase as the word SUCTION. Align the bolt holes.
4. Apply a thin film of clean refrigeration oil on each side of the head gasket.
5. Place the head gasket on the valve plate with the largest hole of the gasket over the largest hole of the valve plate. Line up the holes of the gasket with those of the valve plate.
6. Position the cylinder head on the compressor. **The word SUCTION on the head must be up and on the same side as the word SUCTION on the compressor crankcase.**
7. Align the bolt holes of the cylinder head, gaskets and valve plate with the holes in the compressor crankcase.
8. Install the cylinder head attaching bolts in the bolt holes. The four 12 point head bolts must be inserted in the four holes nearest the head service ports.
9. Tighten the bolts until they contact the top surface of the cylinder head. Then, tighten the head bolts in a sequence so that the bolts diagonally opposite each other are evenly tightened to a torque of 20-24 ft-lbs.

   After the cylinder head has been installed 1/2 hour, retorque the head bolts to 20-24 ft-lbs.
10. Inspect the top of the cylinder head service valve ports to be sure that they are free of nicks and imperfections.

    Connect the service valves with new O-rings to the correct compressor ports and torque to specification.
11. Check the compressor oil level and add or remove oil as required. (See

Compressor Oil Level Check in Adjustments). Evacuate the compressor and connect it back into the system.

CRANKSHAFT SEAL

Removal—All Compressors

1. Isolate the compressor, loosen and remove the belt.
2. Remove the clutch and remove the Woodruff key. Carefully remove the secondary dust shield so as to avoid marring the shaft.
3. Carefully remove all accumulated dirt and foreign material from the seal plate and surrounding area of the compressor, and position a small drain pan beneath the seal plate.
4. Remove the seal plate cap screws, and gently remove the plate and gasket. Do not mar or scratch the sealing surfaces, or the polished shaft surface.
5. Remove the carbon seal ring and seal housing assembly from the crankshaft. A disassembled view of the crankshaft seal assembly is included in Figs. 15 and 16.
6. Clean all old gasket material from the seal plate and the compressor. Make certain that the shaft, the seal plate and the compressor gasket surfaces are completely clean.
7. Check the face of the crankshaft front bearing journal in the seal housing to make certain that there are no nicks or burrs. Check the crankshaft surface to be sure it is not damaged. Check all parts of the seal assembly to be sure that they are not damaged.
8. Inspect the compressor internal components for damage.

Installation—Tecumseh Compressor

1. Wash the new seal assembly components in clean refrigeration oil.
2. Coat the exposed surface of the crankshaft with clean refrigeration oil.
3. Place the seal (Fig. 16) over the compressor shaft with the end that fits the carbon ring facing out.
4. Position the carbon ring over the shaft and to the seal. The raised rim of the carbon ring must face outward.
5. Insert the O-ring in the crankcase mating surface for the seal plate.
6. Position the seal plate, shield and seal plate retainer to the compressor crankcase and align the cover attaching screw holes. Push the seal plate retainer against the mating surface of the crankcase and install the six attaching screws. Torque the screws in a circular sequence to 54-78 in-lb.
7. Rotate the shaft by hand 15 to 20 revolutions to seat the seal.
8. Make certain that there are no burrs or dirt on the compressor shaft. Install the key and magnetic clutch on the shaft.
9. Install the belt and adjust the tension to specifications.
10. Check the compressor oil level (Adjustments).

Installation—York Compressor

1. Wash the new seal assembly components in clean refrigeration oil.
2. Position the seal over the end of the shaft with the carbon ring retainer facing out. Move the seal in and out on the shaft a few times to insure a good seal between the seal and the shaft.
3. Push the seal all-the-way on the shaft. Be sure that the seal drive ring slots engage the drive pins on the shaft bearing journal face.
4. Place the carbon ring (Fig. 15) over the shaft and in the seal ring retainer. The polished surface of the carbon ring must face out and the lugs must engage the ring retainer and be fully seated.
5. Apply a light film of clean refrigeration oil on the matching faces of the crankcase and seal cover plate. Then, place the gasket in position on the crankcase face.
6. Place the seal cover plate in position (Fig. 15), with the polished side facing the carbon ring. Then, install the cap screws. Tighten the cap screws evenly while turning the crankshaft. Be sure that the clearance between the crankshaft and the hole in the seal cover plate is even all around the shaft. If the clearance is not equal all around the shaft, gently tap the seal face into position until the clearance is equal. Then, tighten diagonally opposite cover plate cap screws evenly to 7-13 ft-lb.
7. Make certain that there are no burrs or dirt on the compressor shaft. Install the key and magnetic clutch on the shaft.
8. Install the belt and adjust the tension to specification.
9. Check the compressor oil level (Adjustments).

CLUTCH

1. Loosen and remove the belt.
2. Energize the clutch and loosen and remove the clutch mounting bolt.
3. Install a 5/8-11 bolt in the clutch

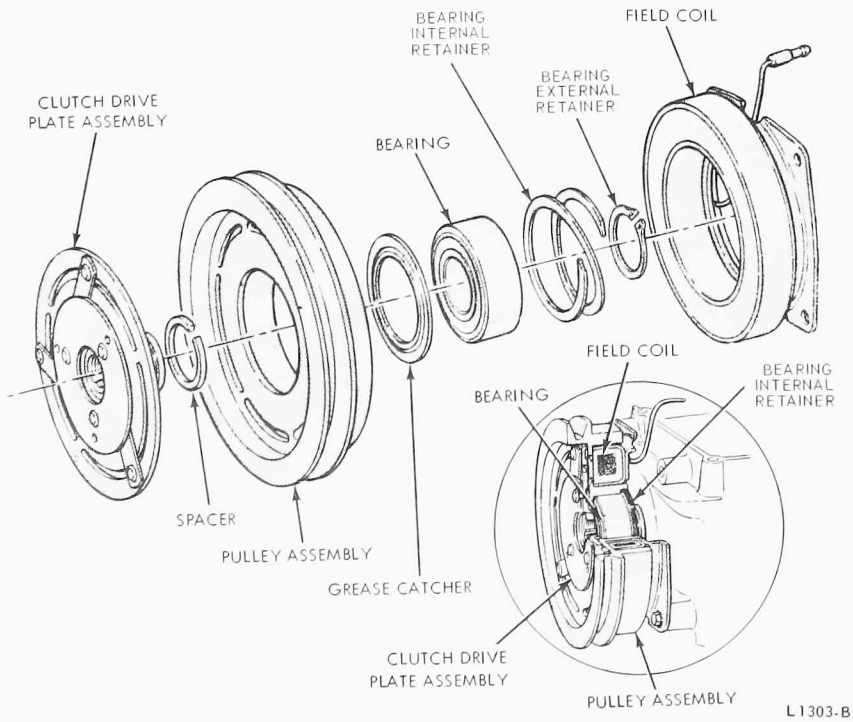

FIG. 17 A/C Clutch Assembly

drive shaft hole. With the clutch still energized, tighten the bolt to loosen the clutch from the shaft, then remove the magnetic clutch.
4. Carefully remove any burrs or dirt that may be on the compressor shaft. The shaft must be dry and brightly polished. Install the clutch, the clutch mounting bolt, and the washer.
5. Energize the clutch, and torque the bolt to specification.
6. Install and adjust the belt.

CLUTCH BEARING

When **installing** a new bearing, be very careful to support the bearing and the clutch assembly so as not to place any pressure on the balls of the bearing.

The following procedure should be rigidly adhered to during bearing replacement. Any exceptions due to clutch design are noted. Refer to Fig. 17.

Removal

1. Remove the clutch assembly from the compressor shaft as outlined in the foregoing procedure.
2. With the clutch assembly face down, remove the bearing external retainer from the drive plate shaft.
3. Support the clutch, face down, by the outer edge so as to clear the drive plate. Insert a 5/8-11 inch bolt through the drive plate shaft and hand tighten the bolt.
4. Smoothly apply enough pressure on the bolt to free the shaft from the bearing inner race and then remove the drive plate assembly. Before proceeding, check the drive face plate for any excessive warping or breakage. Replace the entire clutch assembly if any damage is evident.
5. Remove the bearing internal retainer from the pulley assembly. Support the pulley assembly, face up, by the bearing bore making certain that there is no interference when the bearing is pressed out. With a suitable plug, force the bearing out of the pulley assembly by the inner race. **The plug should clear the metal grease catcher, but do not remove the grease catcher from the pulley assembly.**

Installation

Before installing the bearing, be sure that all bearing contact surfaces are clean.

1. Support the pulley assembly face down, near the bearing bore; but do not support it by the sides of the pulley grooves as this may bend the pulley assembly.
2. Press a new bearing into the bearing bore by the outer race. **Do not press the bearing in by the inner race.** Pressure should be uniform and in line with the axis of the bearing bore. Replace the bearing internal retainer.
3. Support the pulley assembly, face up, by the bearing inner race. Insert a 5/8-11-inch bolt into the front of the drive face plate and carefully press the shaft into the bearing inner race, exerting pressure on the bolt. Be certain that the shaft is in line with the axis of the bearing bore.
4. Replace the bearing external retainer onto the drive plate shaft. Rotate the pulley relative to the drive plate to make certain that there is free rotation and that there is no looseness of the assembly before installing the clutch onto the compressor.
5. Install the clutch assembly on the compressor shaft.

DRIVE BELT

1. Loosen the idler pulley or compressor and remove the belt.
2. Place the new belt in position, and adjust the belt tension (Tool T63L-8620-A) to specification. Then, tighten the idler pulley or compressor.
3. Check the belt alignment, and adjust it if necessary.

Control Assembly	61-09	Registers	61-10

DESCRIPTION AND OPERATION

DESCRIPTION

The heater-air conditioner is an integral unit with the evaporator housing mounted to the engine side of the dash panel. The plenum and air intake is mounted under the instrument panel. The condenser and 40 degree ambient switch are located ahead of the radiator.

The system can be operated with either fresh or recirculated air, depending on the positions of the control levers.

1. With mode (lower) lever on VENT—all air is fresh regardless of the TEMPERATURE lever position.
2. With mode (lower) lever in all other positions—system operates on recirculated air with TEMPERATURE lever on COOL to about 1-1/2 inches toward WARM. Fresh air is used from about 1-1/2 inches toward WARM to WARM position.

The controls are located in the upper center of the instrument panel. The controls consist of two horizontal sliding levers and a blower switch. The top sliding lever is the temperature lever which controls the air blend door, fresh air-recirc. door, and the water valve. The lower sliding (mode) lever controls air distribution to the desired outlets, the blower off switch, and the compressor switch. The blower switch is located to the left of the horizontal sliding levers. This switch controls the blower motor speed only, and will **not** shut the blower OFF.

OPERATION

Air is drawn into the system through the recirculating air door or the fresh air door, through the evaporator core into the evaporator housing. From that point, air is pulled around and/or through the heater core to the blower. The diversion of air through or around the heater core is dependent on the temperature lever setting. From the blower motor, air is forced into the plenum and distributed to the floor, defrosters or registers, depending on the setting of the mode (lower) control lever. Fig. 1 shows the air flow for the various mode lever settings. Fig. 2 shows the effect the temperature lever has on air flow and water valve.

CONTROL OPERATION

The eight-port vacuum selector (located in the control assembly) is operated by the mode (lower) control lever. The rubber diverter plate located in the selector directs vacuum or atmospheric pressures to the ports and thence to the vacuum motors as required by the system. The eight-port selector also comes equipped with the low speed blower switch that is activated when the lever is moved to the VENT position on the control panel. At this point the fresh air door is opened and a forced air ventilation system is in operation. The switch remains closed through the remainder of the lever travel. The second switch on the selector activates the compressor clutch in the PANEL and partial (DELTA) modes only.

In series with the clutch switch is the de-icer switch which senses the temperature of the evaporator core through a capillary tube inserted in the core fins. Should the temperature of the core fall below 28 degrees F, the clutch is deactivated and the core is protected from icing. The de-icer switch is again activated when the core temperature reaches 34 degrees F. The 40 degrees F ambient temperature switch (located on the radiator support) is also connected in series with the clutch circuit and deactivates the clutch when the ambient falls below 40 degrees F. This switch will not reactivate until the ambient temperature reaches 55 degrees F.

The three-port vacuum selector is also located on the control assembly and is operated by the temperature lever. The first 10 degrees of lever travel partially opens the water valve. The movement from 10 degrees to 20 degrees fully opens the water valve and the fresh air door.

The system temperature is further modulated by the movement of the air blend door which controls the amount of cooled air that passes through or by-passes the heater core. The blend door is connected to the temperature lever by a Bowden cable.

The low blower switch, as mentioned above, is located on the eight port selector. If higher blower speeds are desired, they can be obtained by activating the blower switch. This switch has four speeds, Low, two intermediate and High. The blower can only be shut-off by moving the mode (lower) lever to OFF.

ADJUSTMENTS

AIR BLEND DOOR

The only adjustment necessary is the air blend door. This door is connected to the temperature (upper) control lever by a Bowden cable. To adjust, loosen the cable clamp screw (Fig. 5). Move the temperature control lever to the extreme right and hold in that position. Then, rotate the air blend door crank to the extreme rearward position (Fig. 5), and tighten the cable clamp screw.

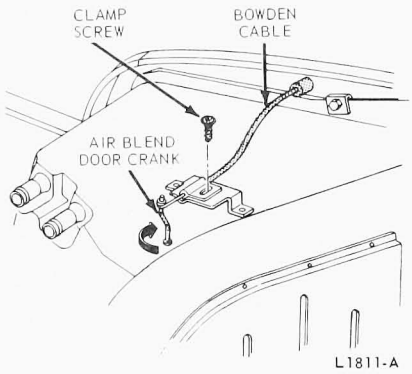

FIG. 5 Air Blend Door Cable Adjustment

REMOVAL AND INSTALLATION

HEATER CORE AND/OR BLOWER MOTOR

Removal

1. Disconnect the battery cable, remove the carburetor air cleaner and drain the coolant from the engine.
2. Remove the heater hoses from the heater core.
3. Remove the A/C hose support from the cowl (Fig. 6).
4. Remove the insulation tape from the expansion valve. Then, remove the cover plate and seal from the evaporator housing at the expansion valve.
5. Remove the glove box liner and the right A/C duct. Pull the duct from the register and release the clip at the plenum for duct removal.
6. Disconnect the vacuum hose from the fresh air door vacuum motor (Fig. 7).
7. Remove evaporator rear housing from dash panel and fresh air inlet boot (Fig. 8). Install one upper nut to retain evaporator front housing to dash after rear housing is removed.
8. Rmove the icing switch and icing switch mounting plate (Fig. 8). Push wire grommet out of the mounting plate.
9. Remove plenum from evaporator front housing and lower plenum down (Fig. 9).
10. Remove 4 screws attaching evaporator core to housing. Pull core away from housing and position up and rearward from housing. This can be done by tying twine to one of the core end tubes, routing the twine through the glove box opening and connecting it to the steering wheel.
11. Remove heater core from evaporator housing (3 screws and 2 plates).
12. To remove the blower, unsnap temperature door from arm, and remove the arm support (2 screws).
13. Remove temperature door arm pivot retainer (1 screw).
14. Remove blower and motor from housing.

Installation

1. Install the blower in the housing.
2. Install the temperature door pivot retainer, support and door in the housing.
3. Install the heater and evaporator cores in the housing.
4. Install the plenum and icing switch. Connect the blower and icing switch wires.
5. Install the evaporator rear housing and connect the fresh air inlet boot to the housing.
6. Connect vacuum hose to the fresh air door vacuum motor.
7. Install the right A/C duct and glove box liner.
8. Install the seal and cover plate on the evaporator housing at the expansion valve.
9. Install the insulation tape on the expansion valve.
10. Install the A/C hose support on the cowl.
11. Connect the vacuum hoses to the intake manifold and the heater hoses to the heater core.
12. Fill the cooling system and install the carburetor air cleaner.
13. Connect the battery ground cable.

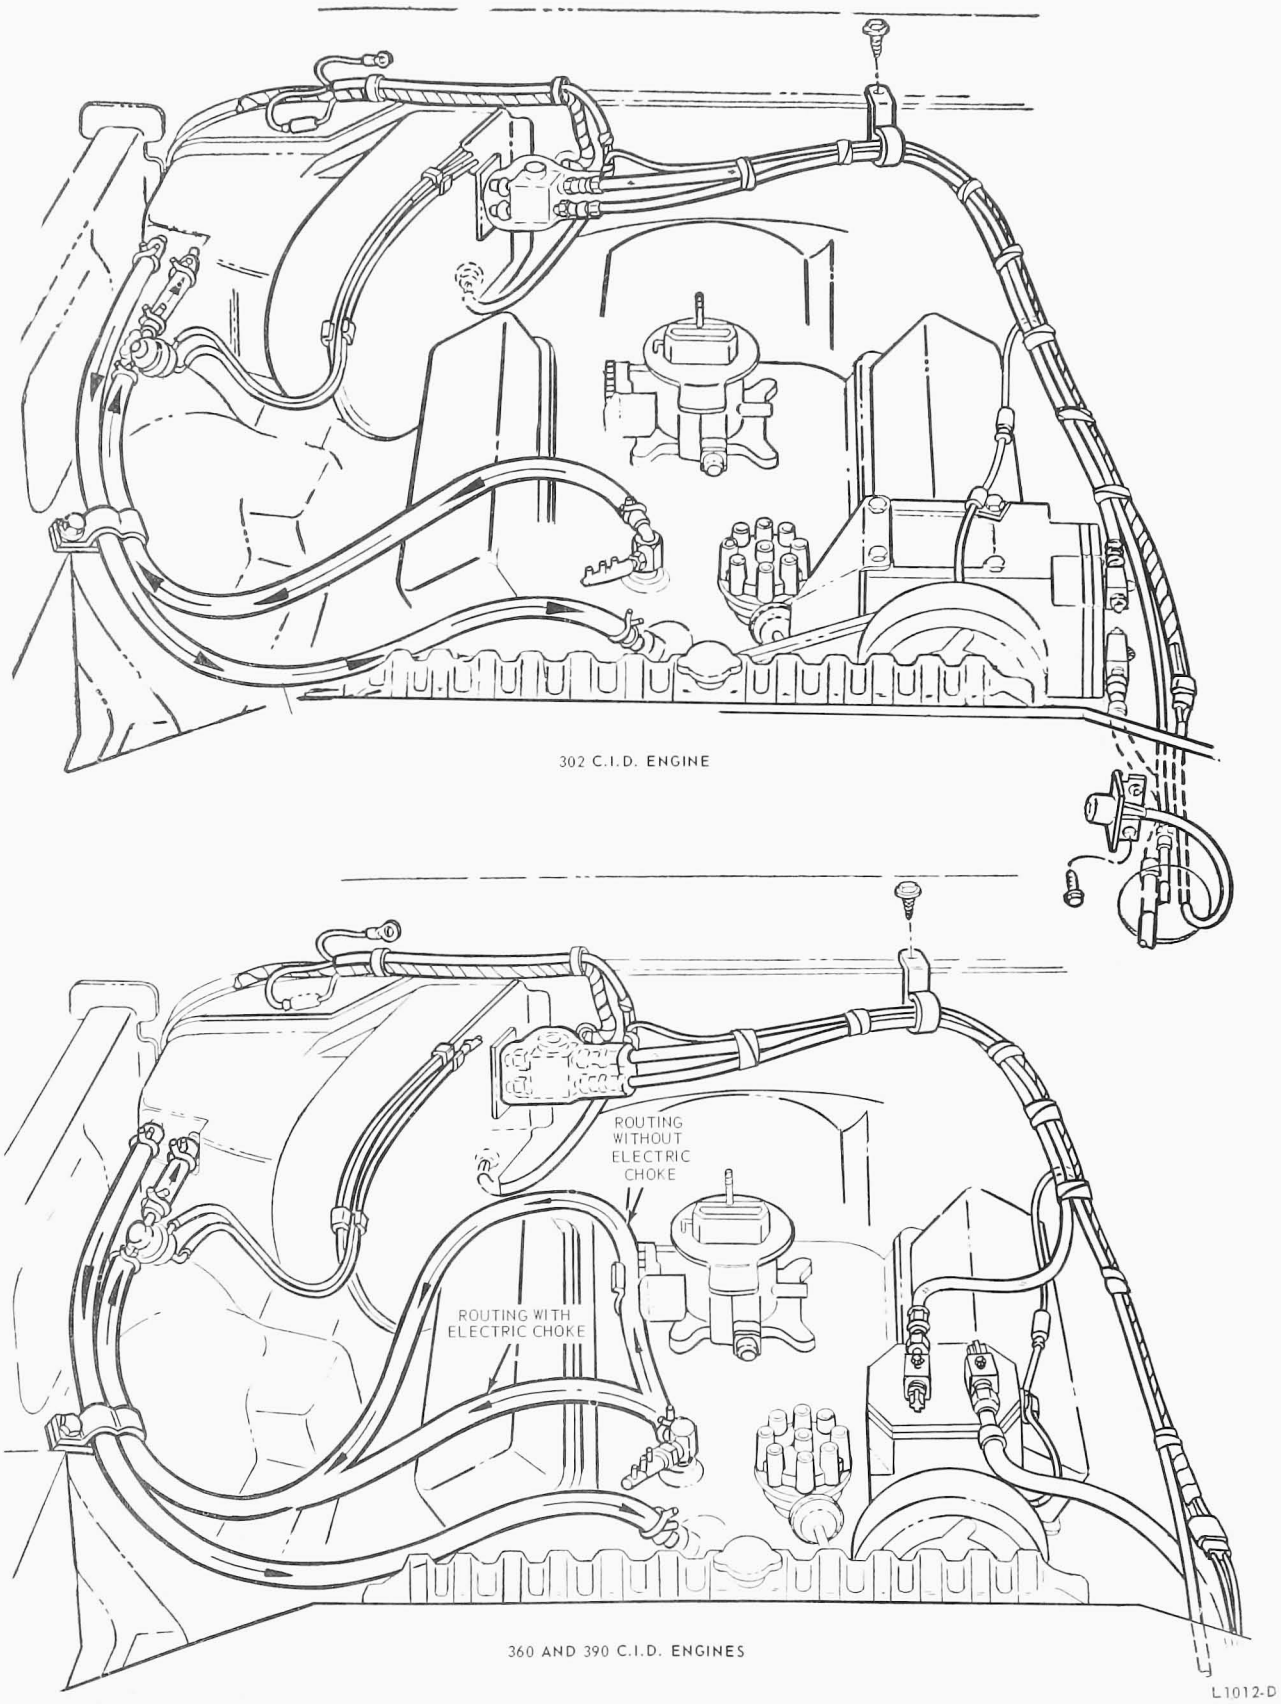

FIG. 6 Heater and A/C Hose Routings

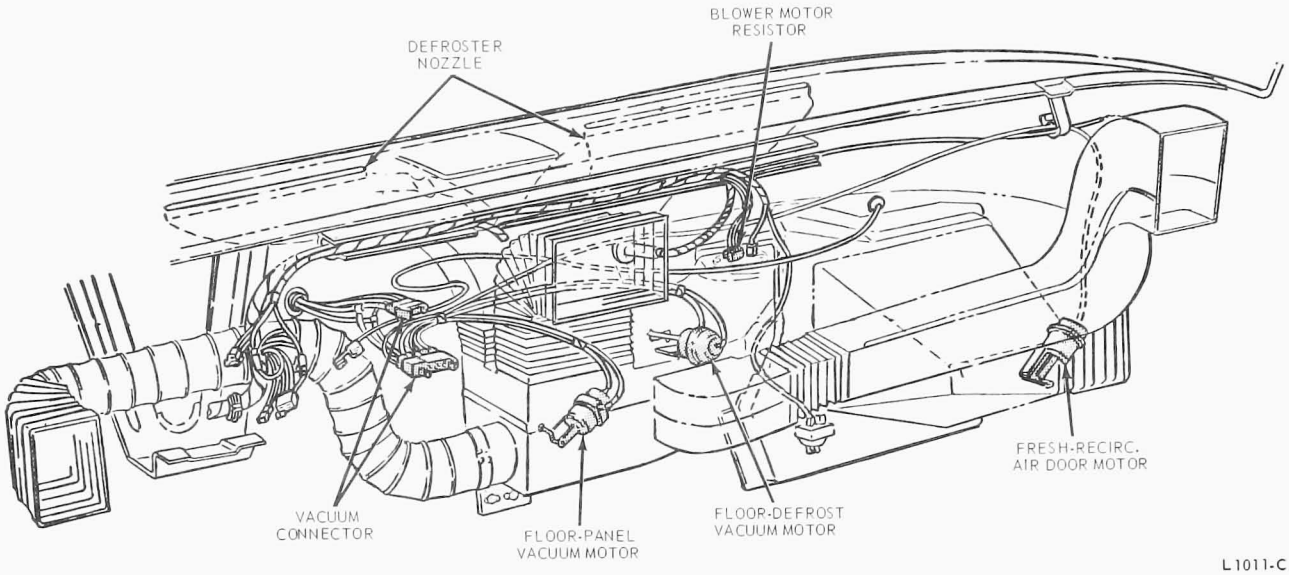

FIG. 7 Heater-Air Conditioner Installation

EVAPORATOR CORE

Removal

1. Disconnect the battery cable and remove the carburetor air cleaner.
2. Discharge the refrigerant from the A/C system. Refer to Part 36-30.
3. Remove the A/C hose support from the cowl (Fig. 6).
4. Remove the insulation tape from the expansion valve. Then, remove the cover plate and seal from the evaporator housing at the expansion valve.
5. Remove the glove box liner and the right A/C duct. Pull the duct from the register and release the clip at the plenum for duct removal.
6. Disconnect the vacuum hose from the fresh air-recirc. door vacuum motor (Fig. 7).
7. Remove evaporator rear housing from dash panel and fresh air inlet boot (Fig. 8). Install one upper nut to retain evaporator front housing to dash after rear housing is removed.
8. Remove the icing switch and icing switch mounting plate (Fig. 8). Push wire grommet out of mounting plate.
9. Remove plenum from evaporator front housing and lower plenum down (Fig. 9).
10. Remove the expansion valve from the evaporator core (Fig. 6).
11. Remove 4 screws attaching evaporator core to housing and remove core.

Installation

1. Position core to evaporator housing and install attaching screws.

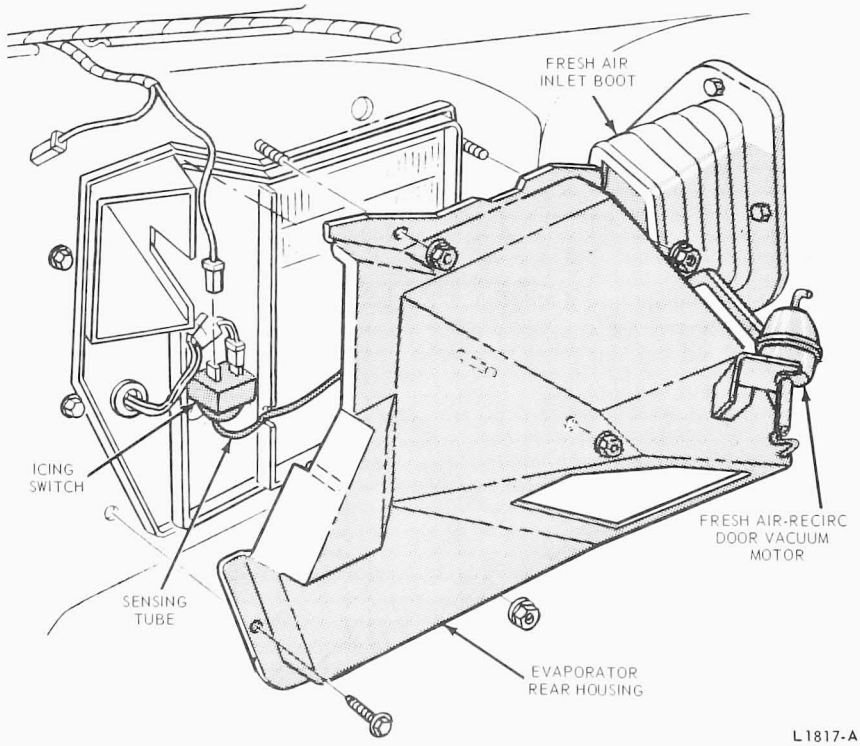

FIG. 8 Evaporator Rear Housing Removal

2. Connect the expansion valve to the evaporator core.
3. Install the plenum and icing switch. Connect the blower and icing switch wires.
4. Install the evaporator rear housing and connect the fresh air inlet boot to the housing.
5. Connect vacuum hose to the fresh air door vacuum motor.
6. Install the right A/C duct and glove box liner.
7. Install the seal and cover plate on the evaporator housing at the expansion valve.
8. Install the A/C hose support on the cowl.
9. Leak test, evacuate, and charge the air conditioning system as outlined in Part 36-30.

10. Install the insulation tape on the expansion valve.
11. Install the carburetor air cleaner.
12. Connect the battery ground cable, and check the system operation.

EXPANSION VALVE

Removal

1. Remove the carburetor air cleaner.
2. Discharge the refrigerant from the A/C system. Refer to Part 36-30.
3. Remove the A/C hose support from the cowl (Fig. 6).
4. Remove the insulation tape from the expansion valve, and remove the expansion valve from the evaporator core tubes and refrigerant lines.

Installation

1. Connect the expansion valve to the evaporator core tubes and the refrigerant lines.
2. Leak test, evacuate, and charge the A/C system as outlined in Part 36-30.
3. Install the insulation tape on the expansion valve.
4. Install the carburetor air cleaner, and check the operation of the A/C system.

ICING SWITCH

Removal

1. Disconnect the battery ground cable.
2. Remove the glove box liner and the right A/C duct. Pull the duct from the register and release the clip at the plenum for duct removal.
3. Disconnect the vacuum hose from the fresh air door vacuum motor (Fig. 6).
4. Remove the evaporator rear housing from the dash panel and the fresh air inlet boot (Fig. 8). Install one upper nut to retain evaporator front housing to dash after rear housing is removed.
5. Disconnect icing switch wires, pull sensing tube from evaporator core, and remove 2 switch attaching screws.

Installation

1. Installing icing switch screws connect wires, and insert sensing tube 4 inches into evaporator core. Be sure sensing tube is placed in notch of housing as shown in Fig. 8.
2. Install the evaporator rear housing and connect the fresh air inlet boot to the housing.
3. Connect the vacuum hose to the fresh air door vacuum motor.
4. Install the glove box liner and the right A/C duct.
5. Connect the ground cable to battery and check operation of A/C system.

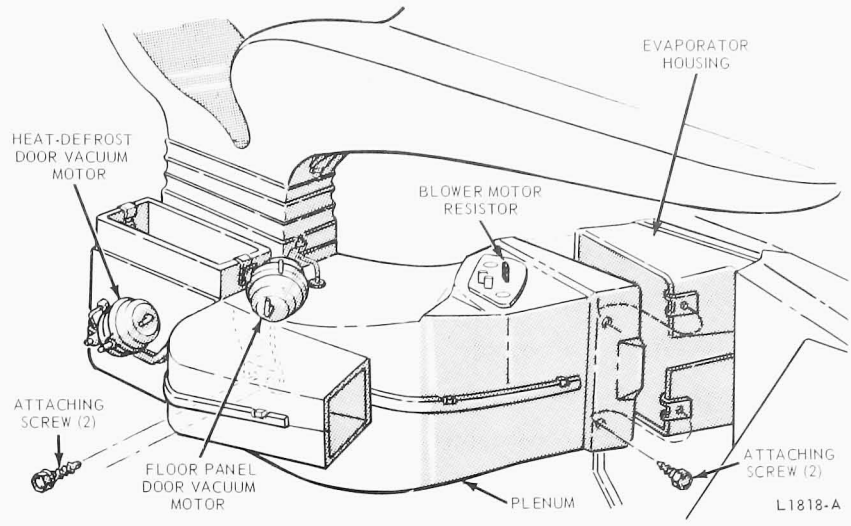

FIG. 9 Heater-A/C Plenum Installation

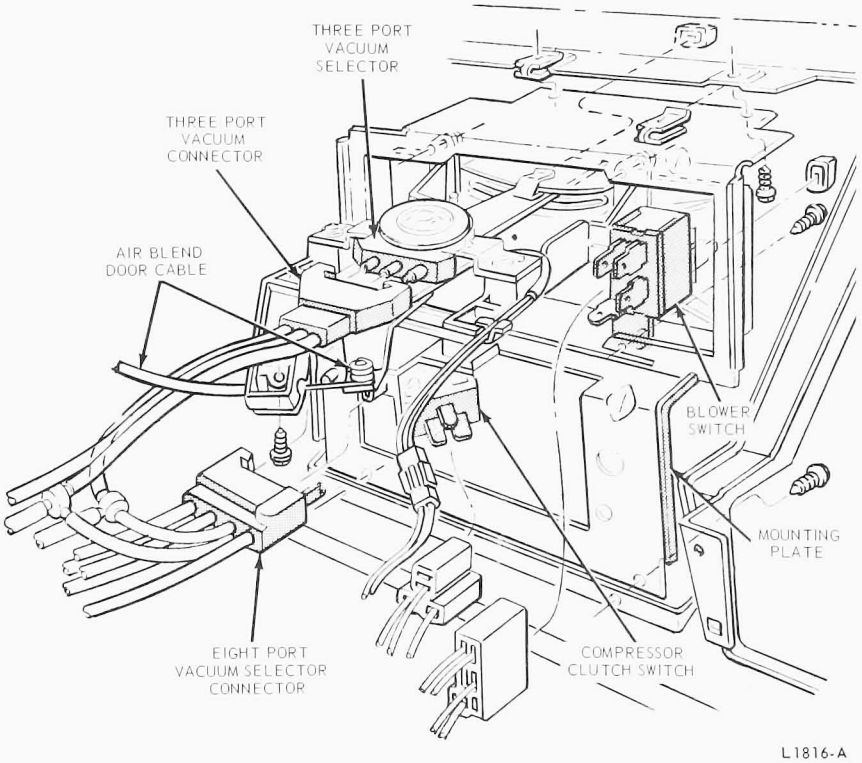

FIG. 10 Heater-Air Conditioner Control Connections

CONTROL ASSEMBLY

1. Remove the instrument cluster as outlined in Group 33 of this manual.
2. Remove 4 screws attaching the control to the mounting plate.
3. Disconnect the wire connectors, vacuum connectors, and Bowden cable from the control (Fig. 10). Then, remove the control assembly.
4. To install, position the control assembly and connect the wire connectors, vacuum connectors, and Bowden cable to the control. The pigtail of the Bowden cable must be up as shown in Fig. 10, and the cable must be routed over the vacuum hoses.
5. Install 4 screws attaching control to mounting plate.

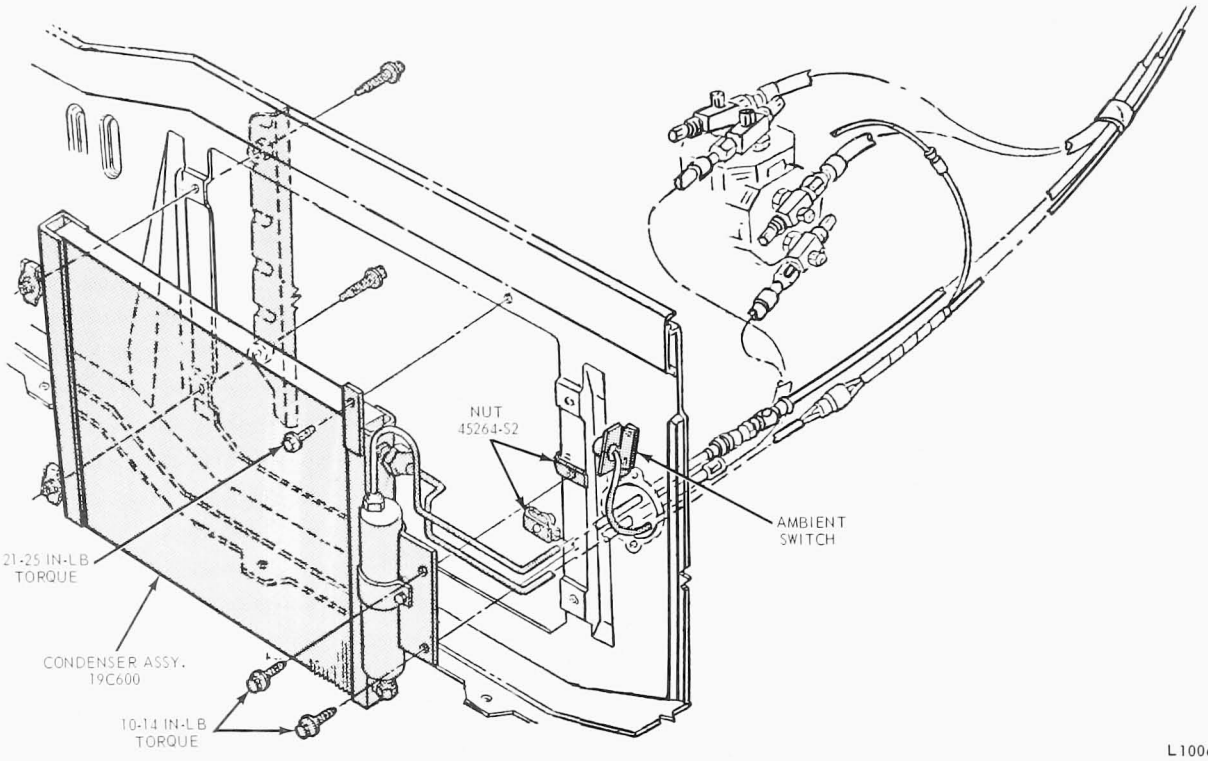

FIG. 11 Condenser and Receiver Tank Installation

6. Install the instrument cluster as outlined in Group 33, and check operation of heater-A/C system.

CONDENSER AND/OR RECEIVER

Removal

1. Discharge the refrigerant from the A/C system. Refer to Part 36-30.
2. Remove the hood latch support (5 screws).
3. Disconnect the refrigerant lines at the receiver tank and condenser (Fig. 11).
4. Remove the condenser and receiver attaching bolts (Fig. 11), and remove the condenser and receiver tank.
5. Separate the receiver tank from the condenser for replacement, if necessary.

Installation

1. Assemble the condenser and receiver.
2. Install the condenser on the radiator support and connect the refrigerant lines.
3. Install the hood latch support.
4. Leak test, evacuate, and charge the air conditioning system as outlined in Part 36-30. Then, check the system operation.

REGISTERS

1. Insert a thin blade or ice-pick through the louvers and carefully pry the tabs (upper and lower) away from the housing to allow the pivots to clear housing. Then, pull louver assembly out of register housing (Fig. 12). Remove both louvers from center register assembly.
2. To remove register housing, pry four lock tabs (2 on each side) inward and pull register housing from instrument panel. The duct must be disengaged from the register housing for removal of the housing.

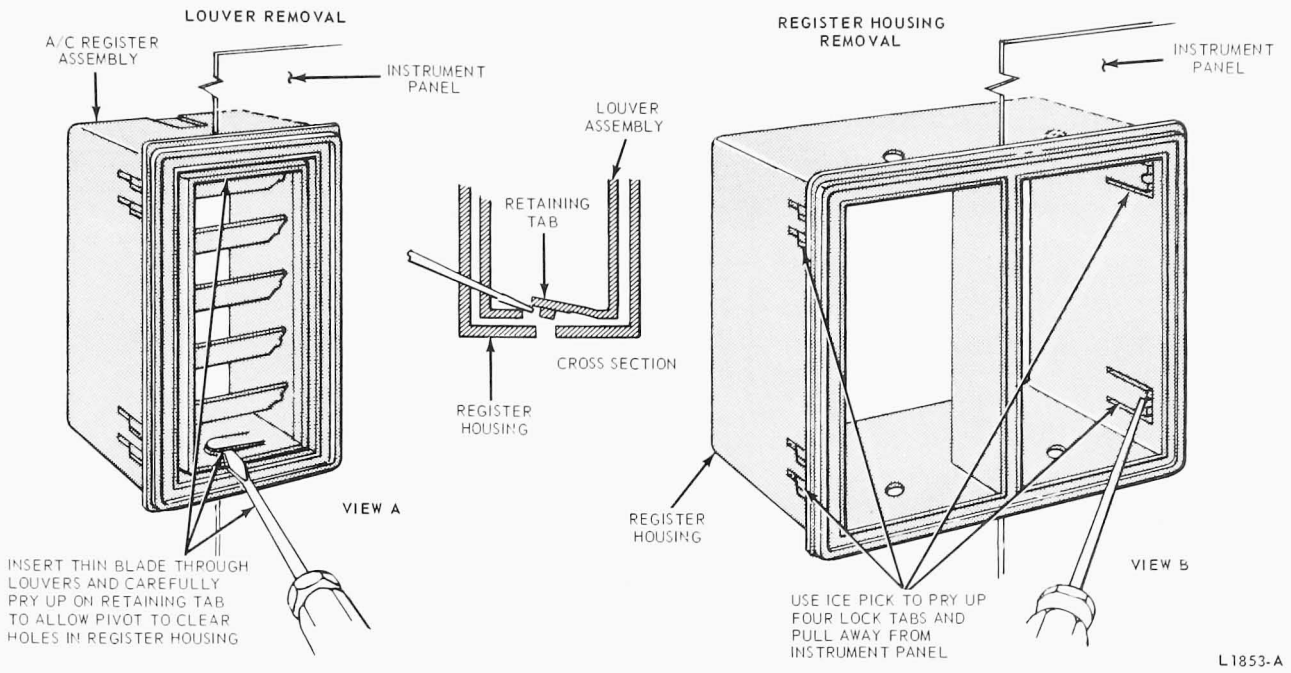

FIG. 12 Instrument Panel Register Removal

Blower Motor Switch	62-06	Receiver Tank	62-07
		Thermostatic Switch	62-06

This part deals with the controls and components that are peculiar to the L-Series truck heater-air conditioning system. Part 36-30 gives the information and procedures required for servicing the refrigeration system which is common to all truck lines. Reference to both parts is necessary for complete servicing of the L-Series system.

DESCRIPTION AND OPERATION

The heater-air conditioner (Figs. 1 or 2) is an integral system with the evaporator housing attached to the lower right side of the dash panel. The evaporator core is located inside the evaporator housing. The condenser is located on the truck cab roof (Fig. 5). The roof mounted condenser lines are routed along the cab right pillar post and are covered by two inspection covers.

Fresh air is used for heater operation and the heated air is directed at the floor area and/or the windshield. Recirculated air is used for air conditioner operation. The cooled air is discharged through the instrument panel registers.

The controls for the unit are located on the right side of the instrument cluster. The controls consist of two vertical sliding levers and a blower switch. The right sliding lever is the temperature lever. The left sliding lever is the heat, defrost and A/C selector lever. The blower switch is located below the sliding levers. **The blower switch must be ON for air conditioner operation.**

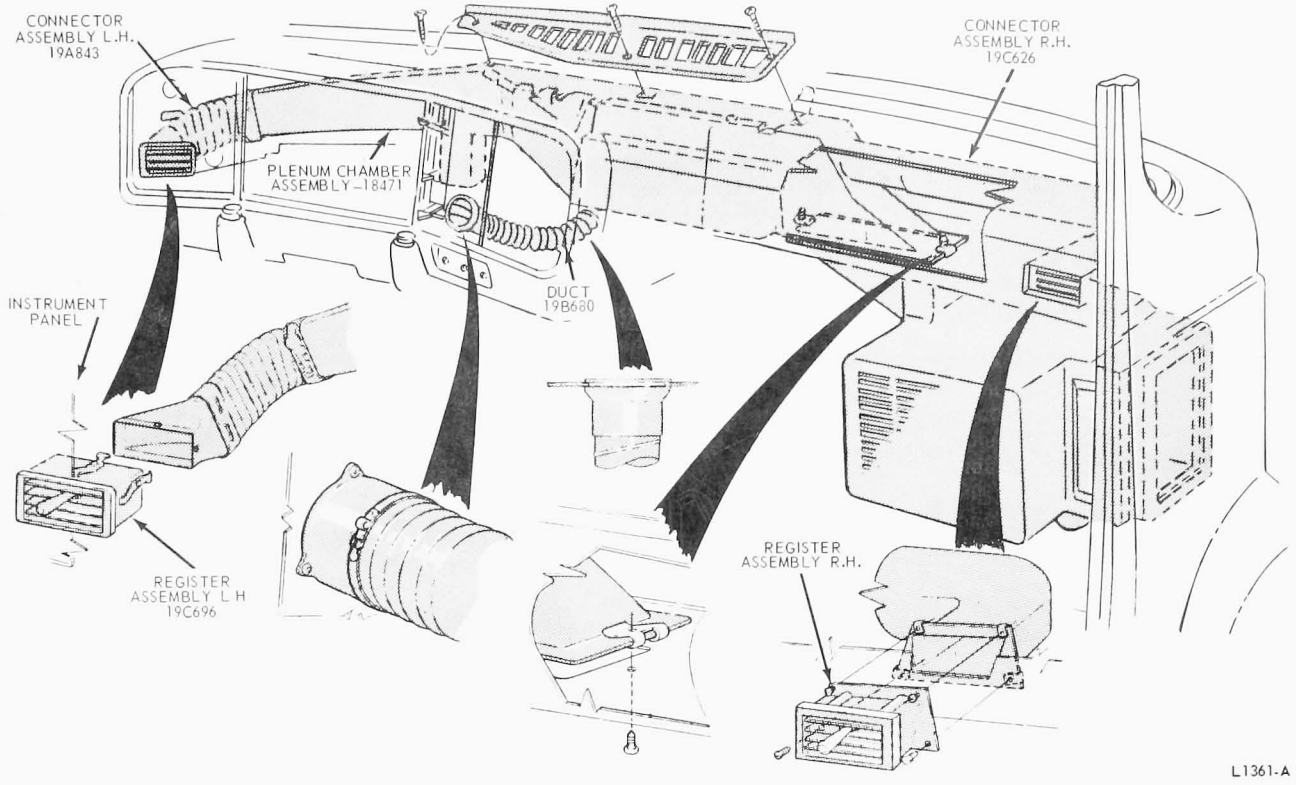

FIG. 1 L-Series Heater-Air Conditioner (Line Haul)

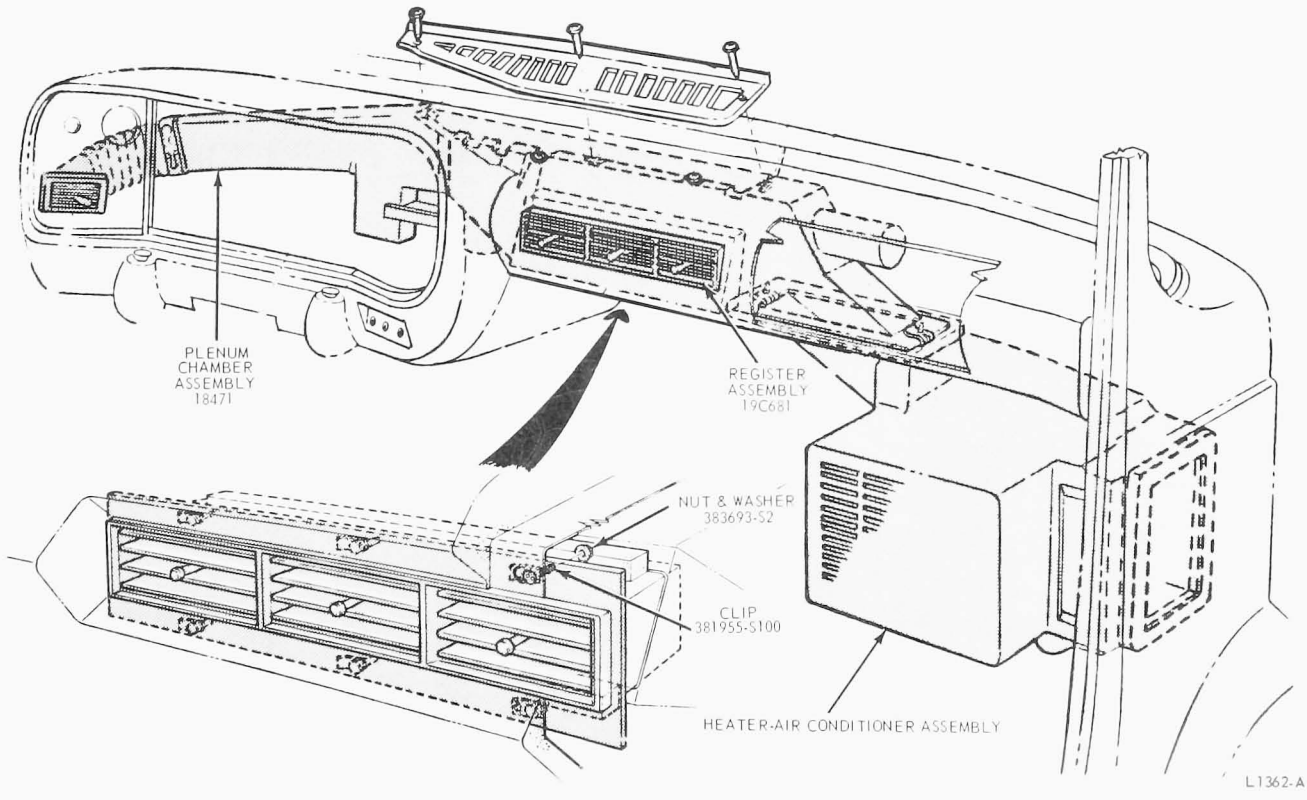

FIG. 2 L-Series Heater-Air Conditioner (City Delivery)

ADJUSTMENTS

A/C-HEAT DOOR CABLE

1. Loosen the cable clamp at the crank arm on the heater-A/C housing (View F, Fig. 3).
2. Move the left control lever to the mid-position of the control head slot. **The control lever must be in the mid-position to obtain proper adjustment.**
3. Move the A/C-heat door crank arm to the full forward position and tighten the cable retaining clamp.

HEAT-DEFROST DOOR CABLE

1. Loosen the cable clamp at the heat-defrost door (View C, Fig. 3).
2. Move the left control lever to the mid-position of the control head slot. **The control lever must be in the mid-position to obtain proper adjustment.**
3. Pull the heat-defrost door crank arm to the full rearward position, and tighten the cable retaining clamp.

THERMOSTATIC SWITCH CABLE

1. Loosen the cable clamp at the thermostatic switch (View G, Fig. 3).
2. Move the right control lever to the mid-position of the control head slot. **The control lever must be in the mid-position to obtain proper adjustment.**
3. Move the thermostatic switch lever all-the-way to the right until it stops. Then, tighten the cable retaining clamp.

HEATER WATER VALVE CABLE

1. Loosen the cable clamp at the water valve (View D, Fig. 3).
2. Move the right control lever to the mid-position of the control head slot. **The control lever must be in the mid-position to obtain proper adjustment.**
3. Push the water valve lever to the full forward position, and tighten the cable retaining clamp.

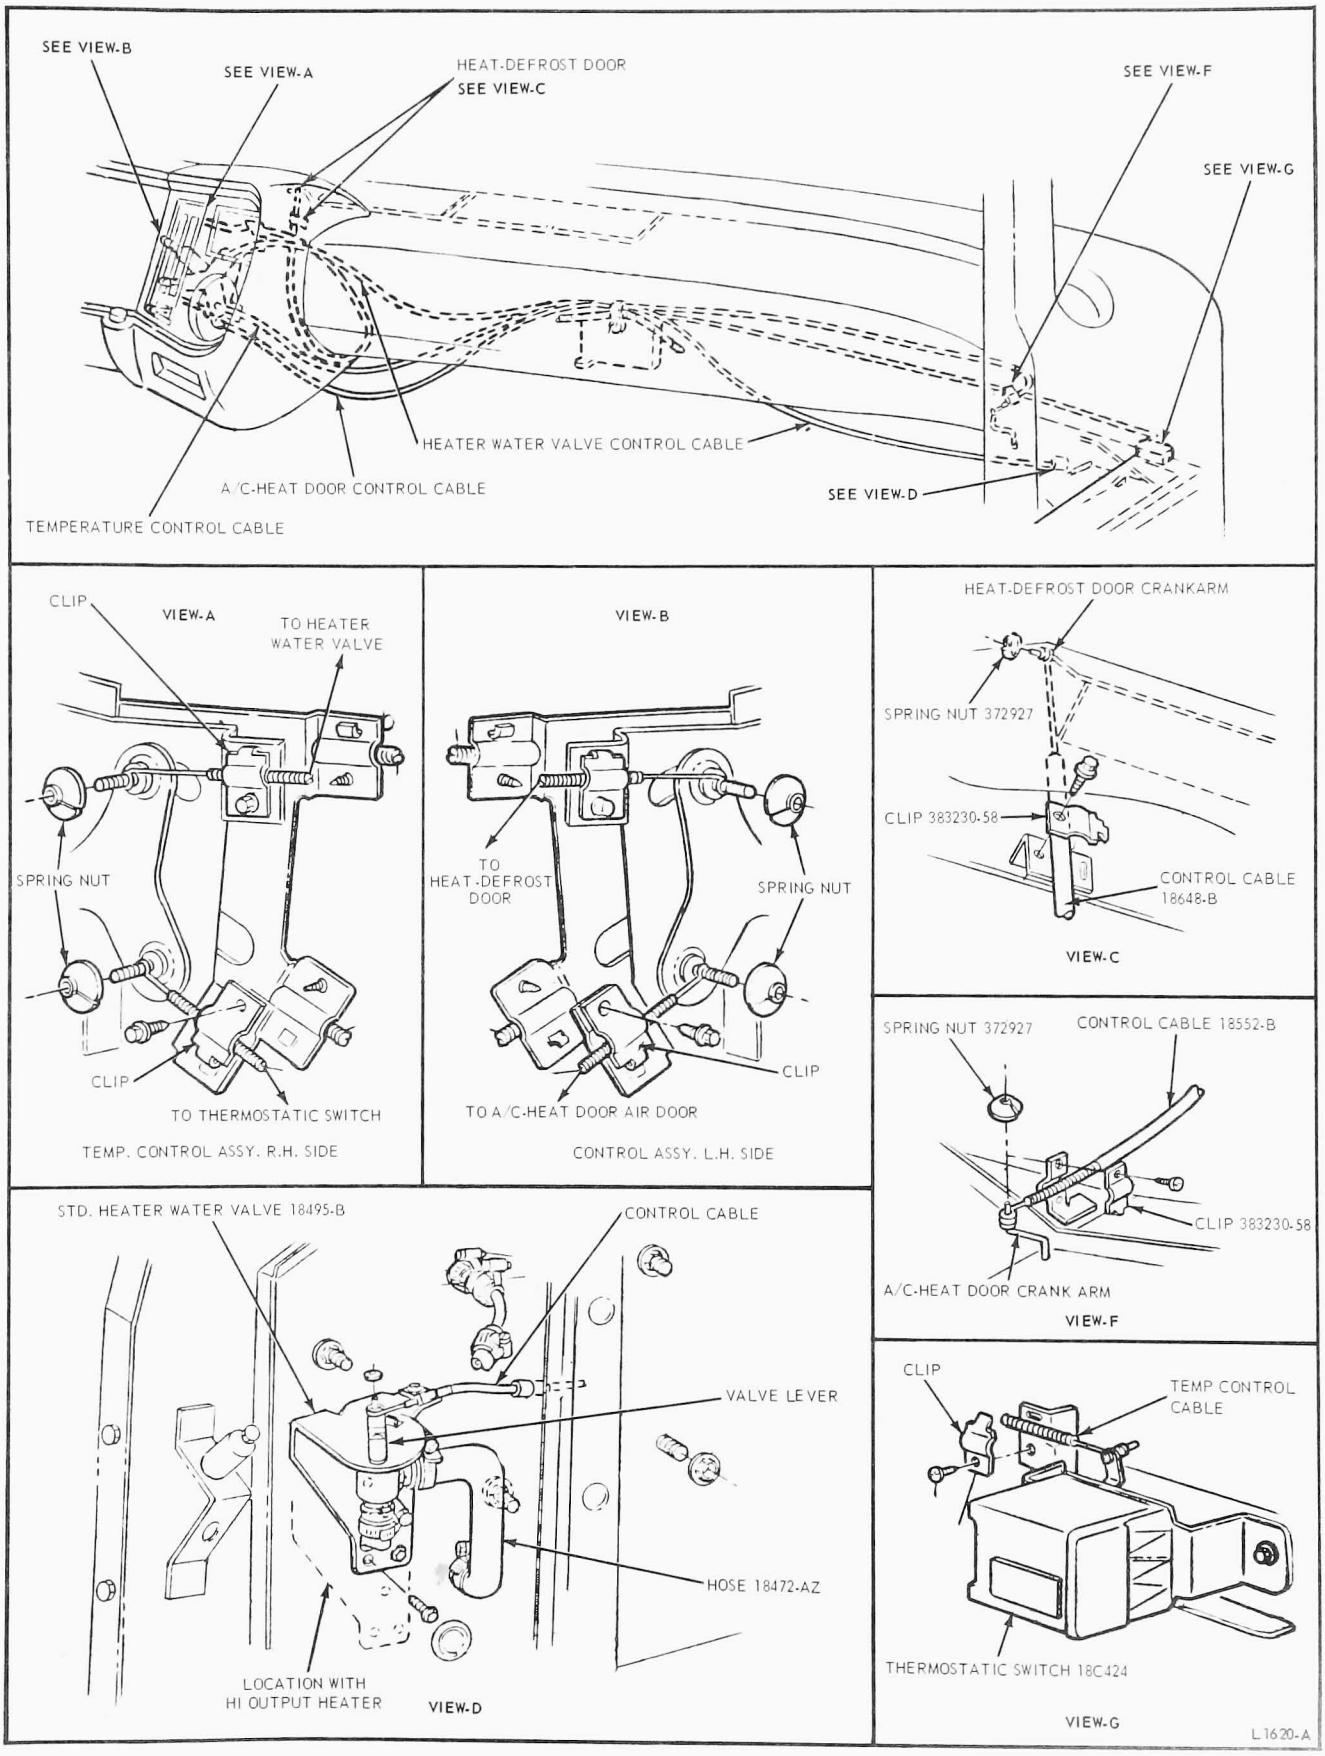

FIG. 3 Heater-A/C Control System—L-Series

REMOVAL AND INSTALLATION

HEATER-AIR CONDITIONER ASSEMBLY

Removal

1. Drain the engine cooling system.
2. Discharge the air conditioning system as outlined in Part 36-30, Adjustments.
3. Disconnect the battery ground cable.
4. Disconnect the refrigerant low pressure hose at the dash panel (Fig. 4).
5. Remove the refrigerant low pressure hose fitting retaining nut and lockwasher.
6. Remove the bolts attaching the heater-air conditioner to the dash panel.
7. Disconnect the drain tube at the bottom of the assembly housing.
8. Disconnect the heater hoses at the bottom of the assembly housing.
9. Disconnect the refrigerant high pressure hose at the side of the assembly housing.
10. Lower the assembly to the vehicle floor and disconnect the Bowden cables from the heater-air conditioner.
11. Disconnect the wires from the blower switch.
12. Disconnect the ground wire.
13. Remove the heater-air conditioner from the vehicle and place on a work bench.

Installation

1. Position the heat-air conditioner assembly in the vehicle (Fig. 4), and connect the refrigerant low pressure hose fitting to the dash panel.
2. Connect the Bowden cables to the heater-air conditioner assembly and adjust as outlined in Adjustments in this part.
3. Connect the wires to the blower switch and connect the ground wire.
4. Position the heater-air conditioner assembly to the dash panel and install the retaining nuts.
5. Connect the refrigerant low pressure hose to the dash panel fitting.
6. Install the heater hoses at the bottom of the assembly.
7. Attach the drain hose to the assembly.
8. Connect the refrigerant high pressure hose on the side of the assembly.
9. Connect the battery ground (-) cable.
10. Fill the cooling system.
11. Leak test, evacuate and charge the air conditioning system (Part 36-30, Adjustments). Then, check the system operation.

EVAPORATOR CORE

Removal

1. Discharge the air conditioning system (Part 36-30, Adjustments).
2. Remove the heater air conditioner assembly from the vehicle.
3. Remove the wire harness from the assembly.
4. Remove the blower resistor from the air conditioner housing.
5. Remove the screws retaining the evaporator core air deflector to the air inlet end of the housing.
6. Remove the housing cover retaining screws and remove the cover from the housing.
7. Remove the evaporator core retaining screws and remove the evaporator core and hoses.
8. Remove the expansion valve and hoses from the evaporator core.

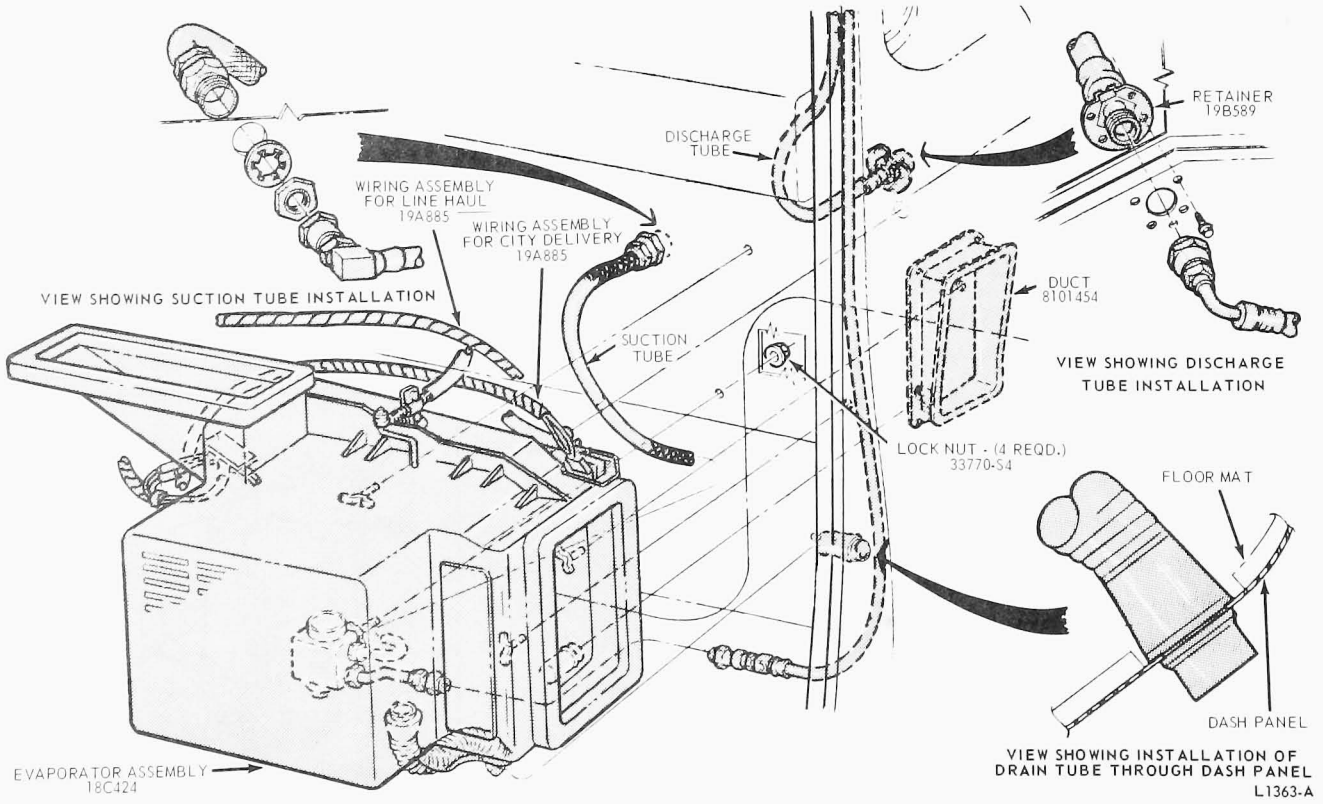

FIG. 4 Heater-Air Conditioner Installation—L-Series Truck

Installation

1. Connect the expansion valve and hoses to the evaporator core. Install the insulation on the expansion valve.
2. Install the evaporator core in the housing.
3. Position the housing cover on the housing and install the cover attaching screws. Install the evaporator core air deflector attaching screws.
4. Install the blower motor resistor.
5. Install the wire harness and clips on the housing.
6. Install the heater-air conditioner in the vehicle.
7. Leak test, evacuate and charge the air conditioning system (Part 36-30, Adjustments). Check the system operation.

HEATER CORE

Removal

1. Remove the heater-air conditioner assembly from the vehicle.
2. Remove the wire harness from the assembly.
3. Remove the blower resistor from the air conditioner housing.
4. Remove the screws retaining the evaporator core air deflector to the air inlet end of the housing.
5. Remove the housing cover retaining screws and remove the cover from the housing.
6. Remove the evaporator core retaining screws and remove the evaporator core and hoses.
7. Remove the blower and adapter plate attaching screws, and remove the blower and adapter plate.
8. Remove the screws attaching the A/C door lever retainers to the door and remove the door from the bellcrank.
9. Remove the screws attaching the evaporator core air deflector to the housing and remove the assembly from the housing.
10. Remove the heater baffle from the housing.
11. Remove the heater core retainer attaching screws and remove the heater core.
12. Remove the insulators from the heater core.

Installation

1. Install the insulators in the heater core.
2. Position the heater core in the housing and install the retainers and attaching screws.
3. Install the heater baffle in the housing.
4. Install the air deflector plate in the housing.
5. Install the A/C door and retainers.
6. Install the blower assembly and adapter plate.
7. Install the evaporator core in the housing.
8. Position the housing cover on the housing and install the cover attaching screws. Install the evaporator core air deflector attaching screws.
9. Install the blower motor resistor.
10. Install the wire harness and clips on the housing.
11. Install the heater-air conditioner in the vehicle.

EXPANSION VALVE

Removal

1. Discharge the air conditioning system (Part 36-30, Adjustments).
2. Remove two screws attaching the thermostatic switch to the heater-air conditioner housing and position the switch to one side.
3. Remove the bolts and nuts attaching the heater-air conditioner to the dash panel. Then, lower the assembly to the floor of the vehicle.
4. Remove the housing cover retaining screws and remove the cover from the housing.
5. Remove the insulation from the expanson valve.
6. Disconnect the refrigerant hoses from the expansion valve.
7. Disconnect and remove the expansion valve from the evaporator.

Installation

1. Connect the expansion valve to the evaporator.
2. Connect the refrigerant hoses to the expansion valve.
3. Install the insulation on the expansion valve.
4. Position the housing cover and install the housing cover retaining screws.
5. Position the heater-air conditioner to the dash panel, and install the attaching bolts and nuts.
6. Place the thermostatic switch in position on the heater-air conditioner housing and install the attaching screws.
7. Leak test, evacuate, and charge the air conditioning system (Part 36-30, Adjustments). Check the system operation.

BLOWER MOTOR

Removal

1. Remove the heater-air conditioner assembly from the vehicle.
2. Remove the wire harness from the assembly.
3. Remove the blower resistor from the housing.
4. Remove the screws retaining the evaporator core air deflector to the air inlet end of the housing.
5. Remove housing cover retaining screws and remove the cover from the housing.
6. Remove the blower and adapter plate attaching screws, and remove the blower and adapter plate.
7. Remove the motor and blower from the adapter plate.

Installation

1. Install the motor and blower on the adapter plate.
2. Position the blower and adapter plate to the housing and install the attaching screws.
3. Position the cover on the housing and install the housing cover retaining screws. Install the evaporator core air deflector attaching screws.
4. Position the blower motor resistor to the housing, and install the attaching screws.
5. Install the wire harness and clips on the housing.
6. Install the heater-air conditioner in the vehicle.

BLOWER MOTOR SWITCH

L-SERIES—LINE HAUL MODELS

1. Remove the battery box cover, and disconnect the ground cable.
2. Remove the strip that retains the instrument cluster side pad (4 screws), and swing the hinged pad down to gain access to the switch.
3. Remove the heater control assembly (4 retaining screws).
4. Remove the control knob from the switch shaft by loosening the set screw, disconnect the push-on connector, and remove the switch from the control assembly (1 retaining screw).

L-SERIES—CITY DELIVERY MODELS

Remove the control knob from the switch shaft by loosening the set screw. Reaching up under the instrument panel, disconnect the multiple connector. Remove the switch-to-heater control retaining screw and remove the switch from under the instrument panel.

THERMOSTATIC SWITCH

Removal

1. Disconnect the wires from the thermostatic switch.
2. Remove two thermostatic switch attaching screws; pull the sensing tube from the evaporator; and

disconnect the control cable from the switch.

Installation

1. Connect the control cable to the thermostatic switch and adjust the cable.
2. Position the switch to the mounting bracket and install the two attaching screws.
3. Insert the sensing tube into the evaporator core.
4. Connect the wires to the thermostatic switch.
5. Check the operation of the air conditioner.

CONDENSER

Removal

1. Discharge the system into the garage exhaust system (Part 36-30, Adjustments).
2. Remove the condenser cover retaining screws and remove the condenser cover (Fig. 5).
3. Disconnect the refrigerant hoses at the condenser tubes.
4. Disconnect the wiring connectors to the condenser motor and the fan switch.
5. Remove the four bolts retaining the condenser assembly to the roof panel.
6. Lift the condenser assembly high enough to provide access to the four nuts holding the condenser coil to the bottom pan of the assembly and remove the four retaining nuts.
7. Lift the condenser out.

Installation

1. To install, position the condenser to the bottom pan and install the four retaining nuts.
2. Install the four bolts retaining the condenser assembly to the roof panel (Fig. 5).
3. Connect the wiring connectors, the condenser motor and fan switch. **Be sure that the wiring routing grommets are securely seated at the point of entry into the roof.**
4. Connect the refrigerant hoses to the condenser coil. **Replace the connector rubber washers.**
5. Water test for leaks through the roof before installing the inspection cover or condenser cover.
6. Position the condenser cover and install the cover retaining screws. The longer screws must go in the top of the condenser cover.
7. Leak test, evacuate and charge the system (Part 36-30, Adjustment).

RECEIVER TANK

Removal

1. Discharge the air conditioning system into the garage exhaust system (Part 36-30, Adjustment).
2. Remove the condenser housing cover and grille assembly (12 screws).
3. Disconnect the inlet and outlet pipes from the receiver and cap the pipe fittings.
4. Loosen the two receiver tank clamp screws and remove the receiver.

Installation

1. Insert the receiver into the clamp and tighten the clamp screws.
2. Connect the inlet and outlet pipes to the receiver.
3. Install the condenser housing cover and grille assembly.
4. Leak test, evacuate and charge the system (Part 36-30, Adjustment).

CONDENSER FAN MOTOR

Removal

1. Remove the condenser housing cover.
2. Loosen the fan bulb set screw and remove the fan from the motor shaft.
3. Disconnect the motor wires at the multiple connector.
4. Remove the motor mounting strap and remove the motor.

Installation

1. Position the motor in the motor cradle and install the mounting strap.
2. Connect the motor wires at the multiple connector.
3. Install the fan on the motor shaft and tighten the hub set screw.
4. Check the surface of the condenser for accumulation of leaves or other foreign material causing restricted air flow around the condenser fins.
5. Install the condenser housing cover.

CONDENSER FAN SWITCH

Removal

1. Remove the cover from the condenser housing.
2. Disconnect the wires from the fan switch.
3. Remove the insulating tape from the temperature sensing bulb and clamp.
4. Loosen the bulb clamp screws and remove the bulb from the clamp.
5. Remove the switch attaching screws and remove the switch.

Installation

1. Position the switch to the sheet metal flange on the condenser head and install the attaching screws.
2. Insert the temperature sensing bulb in the bulb clamp and tighten the clamp screws. Make certain that there is good contact between the bulb and the tube. Any foreign matter will insulate the tube from the bulb and cause malfunction.
3. Wrap the bulb and clamp with insulating tape.
4. Connect the wires to the fan switch.
5. Install the condenser housing cover.

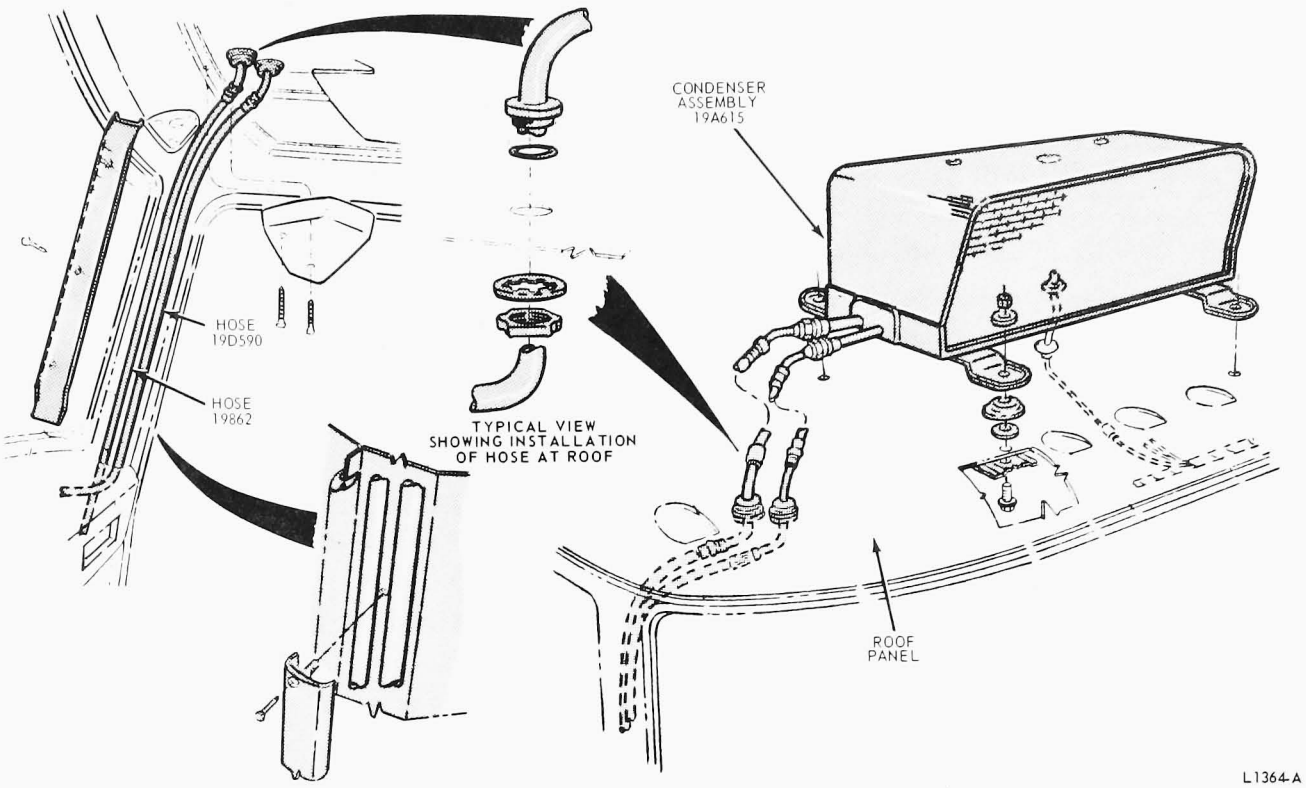

FIG. 5 Condenser Installation—L-Series

PART 36-63 W-Series Truck Heater-Air Conditioning System

Applies To W-Series Truck

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	63-01	REMOVAL AND INSTALLATION - Cont.	
REMOVAL AND INSTALLATION		Evaporator Blower Motor	63-04
Blower Switch	63-04	Evaporator Core and/or Expansion Valve	63-02
Condenser	63-04	Receiver Tank	63-04
Condenser Fan Motor	63-05	Safety Switch	63-04
Condenser Fan Switch	63-05	Thermostatic Switch	63-04

This part deals with the controls and components that are peculiar to the W-Series Truck Heater-Air Conditioning System. Part 36-63 gives the information and procedures required for servicing the refrigeration system which is common to all truck lines. Reference to both parts is necessary for complete servicing of the W-Series system.

DESCRIPTION AND OPERATION

The air conditioner used on W-Series trucks is intergral with the heating system. The evaporator core and heater core are located inside the heater-A/C housing. The condenser is located on the truck cab roof. All parts in the heater and evaporator housing are servicable in the cab. The water shut-off valve and the heater and refrigerant hoses are serviced on the underside of the engine cover.

The refrigerant lines are routed under the cab and are attached to the evaporator. The roof mounted condenser lines are routed along the cab right pillar post and are covered by three inspection covers. There is also an inspection cover in the roof at the point where the lines connect to the condenser.

There are five controls mounted on the left side of the heater-A/C unit. The forward control (No. 1, Fig. 1) operates a fresh-air damper door which should be open (control pulled out) for heater operation. This door should be closed for most efficient A/C operation (control pushed full-in).

The No. 2 knob performs two functions: It controls the temperature by operating the hot water control valve; and it controls the blower switch. Pulling the knob out increases the flow of hot water through the heater core to increase the temperature. Pushing the knob in, shuts off hot water flow through the core for **No Heat** or A/C operation. A shut-off valve at the engine is also provided for summer operation. Turning the knob clockwise turns on the blower for either heating or A/C operation.

The No. 3 control (Fig. 1) operates an air door that routes the discharge air either to the floor or through the frog eyes (moveable registers mounted on the housing cover). During heating operation: pushing the knob in gives minimum defrost through the frog eyes and maximum heat to the floor; pulling the knob out gives maximum defrost or spot defrost through the frog eyes. During A/C operation: pushing the knob in sends cooled air to the floor; pulling the knob out provides spot cooling through the frog eyes.

The No. 4 knob operates the thermostatic control switch, which senses the temperature of the evaporator fins and cycles the compressor on and off to maintain the interior temperature as desired. This control may be turned clockwise to provide cooler air temperature, or counterclockwise to the off position for heater operation. The temperature (thermostatic) control switch is wired in series with the fan switch, compressor clutch and high temperature shut-off switch. The high temperature shut-off switch is mounted on the liquid line inside the evaporator housing (before the expansion valve). This safety shut-off switch protects the system if the condensor system fails, by turning off the compressor clutch when head pressures exceed 360 psi. The switch opens the circuit to the clutch and disengages the compressor. The switch will close when the refrigerant temperature has cooled sufficiently at approximately 250 psi head pressure.

The No. 1 knob (Fig. 1) operates a by-pass damper located above the heater core. Pull the knob to close the door for heat, thereby permitting all of the air to be pulled through the heater core. When the knob is pushed in for air conditioning operation, additonal air delivery will be available because the open door will provide a by-pass air flow

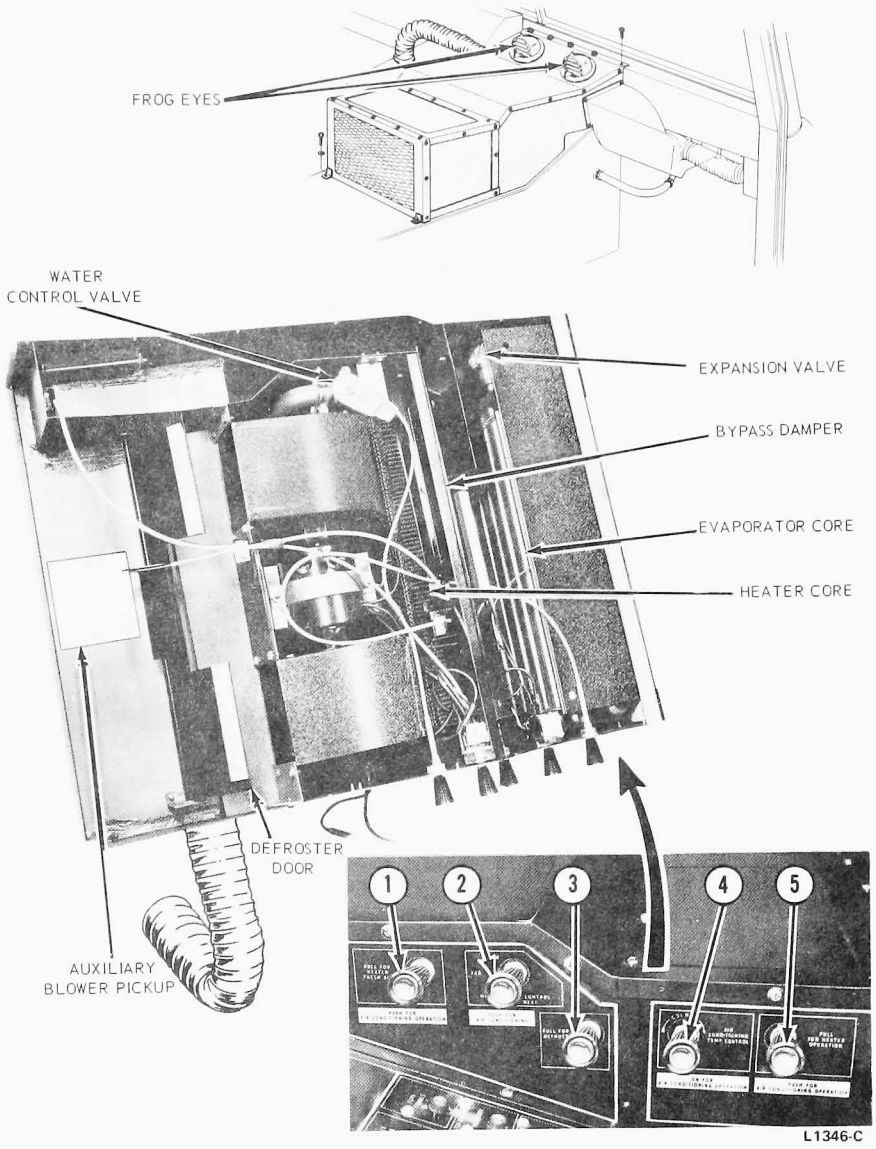

FIG. 1 W-Series Heater-A/C Control Location

over the top of the heater core and thus, reduce the air restriction in the unit.

In addition to the knob controls, frog eyes, and high-pressure safety switch, there is a motor switch in the roof top condenser that turns on the condenser fans when more condensing air is required. The motor switch senses the refrigerant temperature leaving the condenser. The condenser fans operate when the vehicle is stopped or moving slowly, or, when there is insufficient ram air to hold the head pressure down. The switch closes to operate the fans when the temperature in the refrigerant line reaches 135 to 140 degrees F. The condenser fans should start at 250-270 psi head pressure and stop at 200-220 psi head pressure.

The air conditioner electrical circuit has the same basic circuit as the heater blower motor circuit, but with some additional components. These additional components consists of the A/C temperature control, a temperature sensing bulb mounted in the evaporator fins, a high-temperature safety switch mounted on the liquid line inside the evaporator housing, a solenoid to actuate the compressor clutch, and a thermostatic switch to actuate two blower motors in the condenser housing.

REMOVAL AND INSTALLATION

EVAPORATOR CORE AND/OR EXPANSION VALVE

Removal

1. Discharge the system into the garage exhaust system (Part 36-30, Adjustments).
2. Disconnect the two evaporator refrigerant hoses at the underside of the engine cover (Fig. 2).
3. From inside the cab, remove the screws retaining the evaporator grille in place and remove the grille.
4. Remove the screws retaining the rear top cover in place and remove the rear top cover.
5. Remove the screws retaining the evaporator core insulation cover in place and remove the evaporator insulation cover.
6. Disconnect the two spade connectors from the thermostatic switch. Remove the high temperature shut-off switch from its retaining clip on the high pressure refrigerant line to the evaporator.
7. Remove the heater by-pass door operating cable from the heater by-pass door.
8. Remove the two bolts which retain the evaporator and housing assembly to the engine cover.
9. Remove the four screws (two on each side) which retain the evaporator housing assembly to the heater and blower unit. Remove the evaporator from the cab and place the assembly on a bench.
10. Remove the capillary sensing tube of

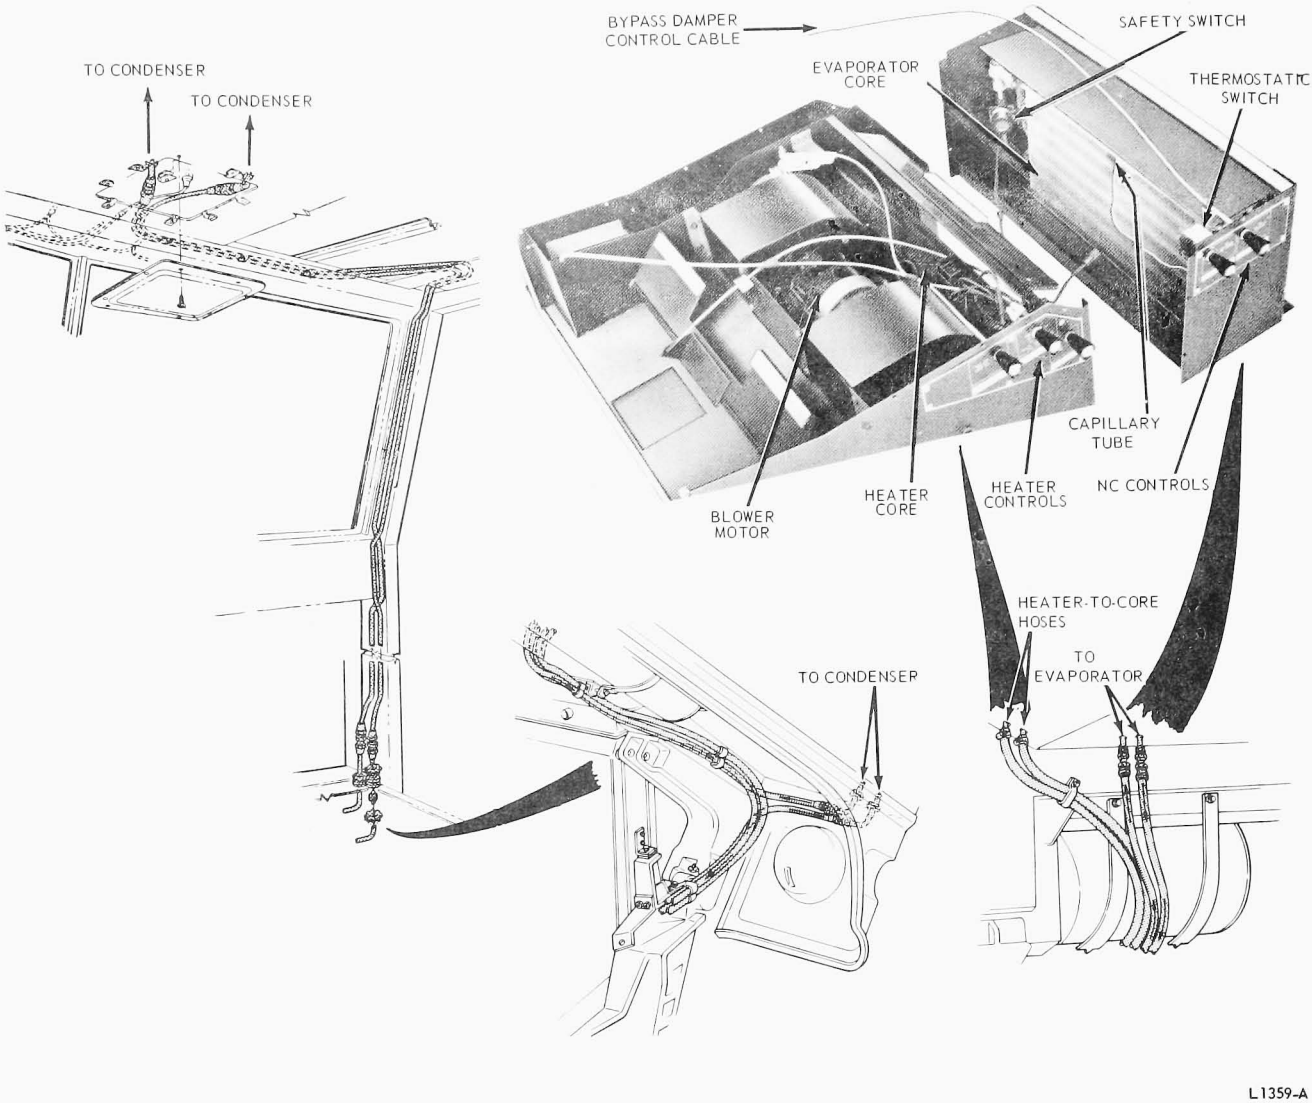

FIG. 2 Heater Air Conditioner Installation—W-Series

the thermostatic switch from the evaporator core. Note the position of the sensing tube so that it can be installed in the same area of the evaporator core during assembly.

11. Remove the screws which retain the evaporator core in its housing. Remove the sponge rubber insulating blocks (on the bottom of the evaporator housing) from around the evaporator inlet and outlet lines and lift the evaporator core from its housing.
12. Remove the insulating type covering the expansion valve sensing bulb clamp.
13. Remove the fitting on the inlet side of the expansion valve.
14. Loosen the flare nut and remove the expansion valve.

Installation

1. Install the expansion valve on the evaporator inlet pipe. Position the sensing bulb to the evaporator outlet pipe and retaining clamp and insulation.
2. Position the evaporator assembly in its housing and install the evaporator to housing retaining screws.
3. Position the sponge rubber insulating block around the evaporator inlet and outlet pipes on the bottom of the evaporator housing.
4. Insert the thermostatic switch capillary sensing tube in the evaporator core at the same location from which it was removed.
5. Position the evaporator assembly to the blower motor assembly in the cab and install the evaporator housing-to-blower motor housing reaining screws.
6. Install the two bolts which retain the evaporator and hoing assembly to the engine cover.
7. Install the heater by-pass door operating cable.
8. Install the high temperature shut-off switch retaining clamp and switch. **Make certain that there is no foreign material between the switch body and the refrigerant line. The switch is heat sensitive and any insulation between the switch body and its mounting point will cause a malfunction.**
9. Install the two spade wiring

connectors on the thermostatic switch assembly.
10. Position the evaporator core insulated-top cover and install the cover retaining screws.
11. Position the rear top cover retaining screws.
12. Position the evaporator grille and install the grille retaining screws.
13. Connect the two refrigerant hoses to the evaporator inlet and outlet pipes at the underside of the engine cover.
14. Leak test and charge the system.

EVAPORATOR BLOWER MOTOR

Removal
1. Remove the top cover attaching screws and remove the cover.
2. Remove eight screws attaching the two blower wheel housings to the heater-A/C housing.
3. Remove the Bowden wire clip holding the wire to air conditioner heat door and loosen the wire from the door.
4. Remove the two motor mounting strap attaching nuts and remove the strap.
5. Disconnect the motor leads from the blower switch and remove the blowers and motor from the housing.
6. Remove two nuts from each side of the motor and remove the blower housings.
7. Remove the set screw in each blower wheel hub and remove the blower wheels. **Note the rotation and blower wheel location before removing the wheels so they can be replaced in the same location.**

Installation
1. Position the blower wheels on the motor shaft in the same location as before removal and tighten the set screws. **Be sure they are installed on the correct side for proper rotation.**
2. Install the blower housings over the blower wheels.
3. Position the blower motor and wheels in the motor saddle.
4. Connect the blower motor wires to the blower switch.
5. Install the motor retaining strap.
6. Connect the Bowden wire to the air conditioner heat door. Adjust the cable and secure it in place with the cable clip.
7. Install the eight blower wheel housing attaching screws.
8. Check the operation of the blower motor and check to be sure that the blower wheels turn free. Then, install the housing top cover.

THERMOSTATIC SWITCH

Removal
1. Remove the grille and rear top cover from the heater-A/C housing.
2. Disconnect the two thermostatic switch wires.
3. Remove the thermostatic switch capillary tube from the evaporator core (Fig. 2). **Note the tube location in the core so that it can be installed in the same locations.**
4. Loosen the set screw and remove the knob from the thermostatic switch.
5. Remove the nut retaining the thermostatic switch to the housing and remove the switch.

Installation
1. Position the switch to the housing and install the retaining nut and knob.
2. Insert the capillary tube between the evaporator core fins in the same location as before removal.
3. Connect the two thermostatic switch wires.
4. Install the heater-A/C housing rear top cover and grille.

SAFETY SWITCH

Removal
1. Remove the rear grille assembly from the heater-A/C housing.
2. Remove the rear top cover from the housing.
3. Disconnect the safety switch wires (Fig. 2).
4. Insert a screwdriver between the switch and switch clamp. Then, twist the screwdriver and remove the switch.

Installation
1. Be sure that the refrigerant tube is clean and can make good contact with the switch. Then, insert the switch in the spring clamp. **Any foreign matter between the switch and the refrigerant tube will act as an insulator and cause malfunctions.**
2. Connect the safety switch wires.
3. Install the rear top cover and rear grille assembly on the heater-A/C housing.

BLOWER SWITCH

Removal
1. Remove the top cover from the housing.
2. Remove the clip retaining the Bowden cable to the water valve and disconnect the wire from the valve.
3. Disconnect the wires from the blower switch.
4. Remove the switch retaining nut and remove the switch.

Installation
1. Position the switch to the housing and install the retaining nut.
2. Connect the wires to the blower switch.
3. Connect the Bowden cable to the water valve and install the retaining clip.
4. Install the housing top cover.

CONDENSER

Removal
1. Discharge the system into the garage exhaust system.
2. Remove the condenser cover retaining screws and remove the condenser cover (Figs. 3 and 4).
3. Disconnect the refrigernat hoses at the condenser coil.
4. Disconnect the wiring connectors to the condenser motor and the fan switch.
5. Remove the four bolts retaining the condenser assembly to the roof panel.
6. Lift the condenser assembly high enough to provide access to the four nuts holding the condenser coil to the bottom pan of the assembly and remove the four retaining nuts.
7. Lift the condenser out.

Installation
1. To install, position the condenser to the bottom pan and install the four retaining nuts.
2. Install the four bolts retaining the condenser assembly to the roof panel.
3. Connect the wiring connectors, the condenser motor and fan switch. **Be sure that the wiring routing grommets are securely seated at the point of entry into the roof.**
4. Connect the refrigerant hoses to the condenser coil. **Replace the connector rubber washers.**
5. Water test for leaks through the roof before installing the inspection cover or condenser cover.
6. Position the condenser cover and install the cover retaining screws. The longer screws must go in the top of the condenser cover.
7. Leak test, evacuate and charge the system.

RECEIVER TANK

Removal
1. Discharge the air conditioning system into the garage exhaust system (Part 36-30, Adjustments).

2. Remove the condenser housing cover.
3. Disconnect the inlet and outlet pipes from the reciever and cap the pipe fittings.
4. Loosen the two reciever tank clamp screws and remove the receiver.

Installation

1. Insert the receiver into the clamp and tighten the clamp screws.
2. Connect the inlet and outlet pipes to the receiver.
3. Leak test, evacuate and charge the system (Part 36-30, Adjustments).
4. Install the condenser housing cover.

CONDENSER FAN MOTOR

Removal

1. Remove the condenser housing cover.
2. Loosen the fan bulb set screw and remove the fan from the motor shaft.
3. Disconnect the motor wires at the multiple connector.
4. Remove the motor mounting strap and remove the motor.

Installation

1. Position the motor in the motor cradle and install the mounting strap.
2. Connect the motor wires at the multiple connector.
3. Install the fan on the motor shaft and tighten the hub set screw.
4. Check the surface of the condenser for accumulation of leaves or other foreign material causing restricted air flow around the condenser fins.
5. Install the condenser housing cover.

CONDENSER FAN SWITCH

Removal

1. Remove the cover from the condenser housing.
2. Disconnect the wires from the fan switch.
3. Remove the insulating tape from the temperature sensing bulb and clamp.
4. Loosen the bulb clamp screws and remove the bulb from the clamp.

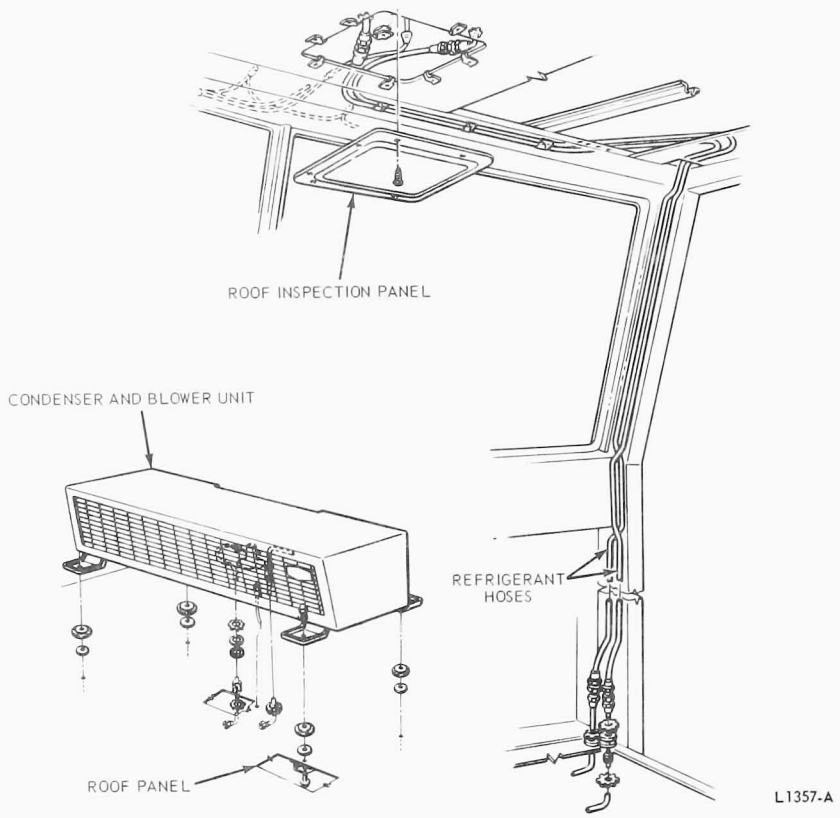

FIG. 3 Condenser Installation—W-Series

5. Remove the switch attaching screws and remove the switch.

Installation

1. Position the switch to the condenser head sheet and install the attaching screws.
2. Insert the temperature sensing bulb in the bulb clamp and tighten the clamp screws. Make certain that there is good contact between the bulb and the tube. Any foreign matter will insulate the tube from the bulb and cause malfunction.
3. Wrap the bulb and clamp with insulating tape.
4. Connect the wires to the fan switch.
5. Install the condenser housing.

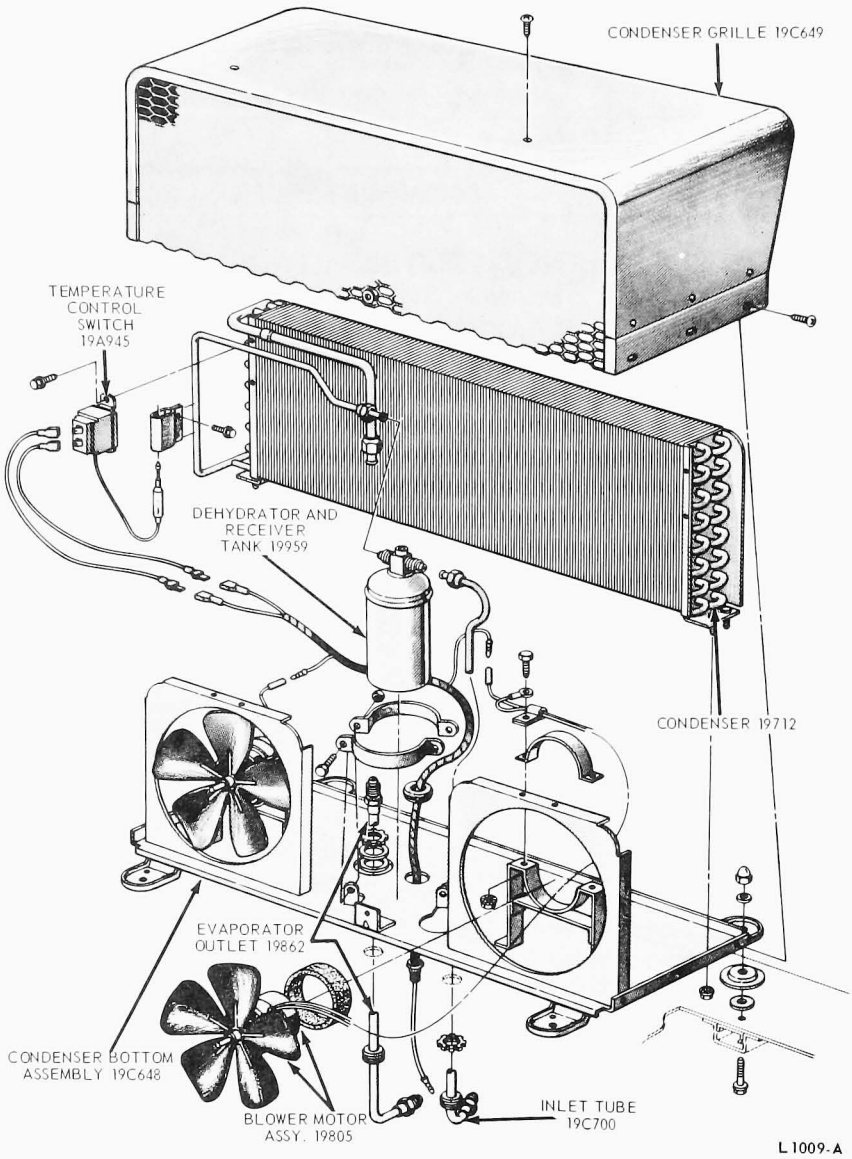

FIG. 4 W-Series Condenser, Receiver and Fan Installation

PART 36-64 C-Series Truck Air Conditioning System

Applies To C-Series Trucks

COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	64-01
REMOVAL AND INSTALLATION	
Blower Switch	64-04
Condenser	64-03
Condenser Fan Motor	64-05
Condenser Overheat Switch	64-04
REMOVAL AND INSTALLATION - Cont.	
Evaporator Blower and Motor	64-04
Evaporator Core	64-02
Expansion Valve	64-03
Receiver Tank and/or Sight Glass	64-04
Relay and Circuit Breaker	64-05
Roof Mounted A/C Unit	64-02
Thermostatic Switch	64-05

This part deals with the controls and components that are peculiar to the C-Series truck air conditioning system. Part 36-30 gives the information and procedures required for servicing the refrigeration system which is common to all truck lines. Reference to both parts is necessary for complete servicing of the C-Series system.

DESCRIPTION AND OPERATION

The air conditioner used on C-Series trucks is installed on the cab roof, and directs cooled air into the cab through the roof mounted control panel and air register. All components of the system except the compressor and connecting refrigerant lines and electrical system wires are encased in the roof unit. This includes the condenser receiver tank, condenser blower, evaporator, evaporator blower, expansion valve and condenser overheat switch.

The refrigerant lines, which are used to transfer refrigerant between the compresor and the roof unit, are shown in Fig. 1. The refrigerant lines are connected to the frame side rail near the compressor and routed forward to the cab hinges. They are then routed rearward along the cab lower reinforcement, up the rear of the cab, and across the top of the cab to the roof unit.

Blower speed is controlled by the front knob on the roof control panel and the air temperature adjustment is the rear control knob. Temperature of the incoming air is maintained at the desired level by an adjustable thermostatic switch. This switch is actuated by changes in evaporator temperature. A rise in temperature closes the switch energizing the magnetic clutch and puts the compressor into operation. As the temperature reaches the desired low point, the thermostatic switch opens and the compressor stops. A condenser overheat switch is also used in this circuit. This switch will open the clutch circuit if the condenser overheats (Fig. 1).

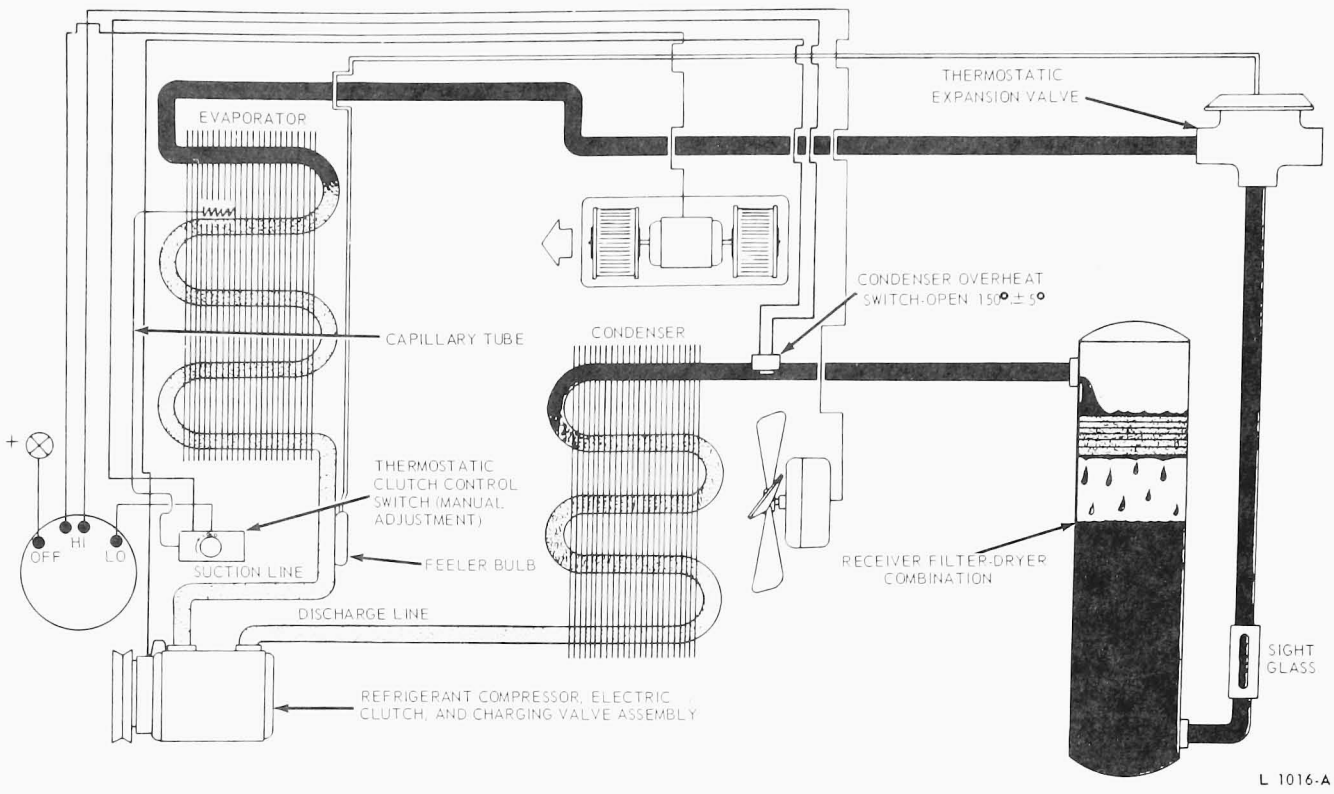

FIG. 1 Air Conditioning System Schematic— C-Series

REMOVAL AND INSTALLATION

ROOF-MOUNTED A/C UNIT

In cases of serious damage, or if for any other reason, it is desired to remove the entire air conditioning unit from the cab (Figs. 2 and 3), the following procedure should apply.

Removal

1. Discharge the system into the garage exhaust system.
2. Disconnect the hoses that lead to the compressor (Fig. 2) and cap the hoses and fittings. Tag these for correct connection later.
3. Disconnect the drain hose from the drain tube and clamp.
4. Remove the four top mounting nuts.
5. Raise the unit and block it up.
6. Reach under the unit and with a sharp knife cut all the way around the joint seal boot.
7. Disconnect the wires and remove the air conditioner from the cab.
8. Remove the bolts holding the joint seal boot to the bottom of the air conditioner, and remove the remains of the joint seal boot.
9. Remove the cemented portion of the joint seal boot from the roof of the cab and thoroughly clean the cemented area.

Installation

1. Bolt a new joint seal boot to the bottom of the air conditioner.
2. Apply a good coat of cement using care to distribute it evenly around the opening in the cab roof. Be sure to cover the area at least one inch out from the opening.
3. Apply cement to the joint seal boot flange using care to distribute it evenly and over the entire flange area.
4. Position the air conditioner in place blocking it up for clearance.
5. Reaching beneath the unit, position the joint seal boot flange and press it to the truck cab roof with the fingers. Work all air pockets from beneath the flange. Press firmly.
6. Connect the drain hose to the drain tube and install the clamp.
7. Connect the wires and remove the temporary blocks and install the air conditioner securing it at four positions.
8. Before installing the four top mounting bolts, check to be certain that the unit is correctly positioned.

It is advisable to slant the unit slightly so that the rear is lower than the front to promote drainage of condensed moisture through the drain tube.

9. Install the four top mounting bolts.
10. Connect the hoses that lead to the compressor taking special care to attach them to the connector that they were marked for during removal.
11. Leak test, evacuate and charge the system (Part 36-30).

EVAPORATOR CORE

1. Discharge the air conditioning system into the garage exhaust system (Part 36-30).
2. Remove the screws which retain the covering hood, and remove the hood and screen.

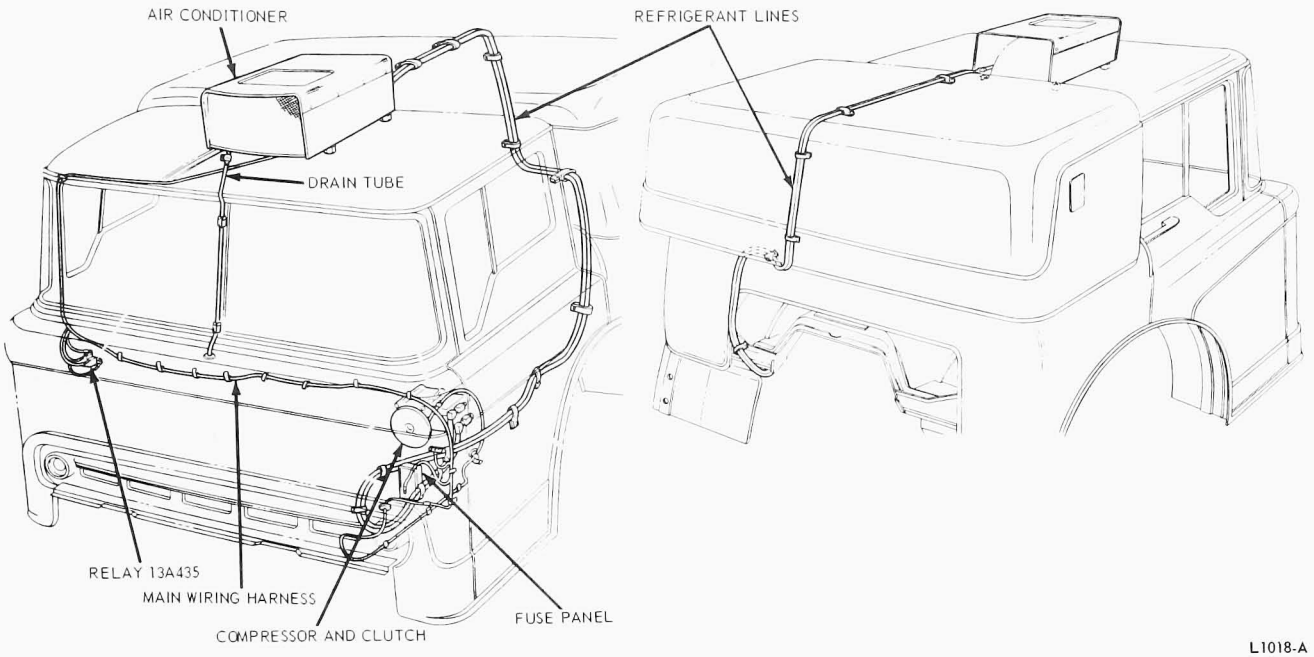

FIG. 2 Air Conditioner Installation—C-Series

3. Remove the evaporator cover, retaining screws, and remove the evaporator cover.
4. Disconnect the expansion valve and the evaporator outlet tube from the evaporator (Fig. 4).
5. Remove 2 nuts attaching the lower front edge of the evaporator to the bottom of the unit housing.
6. Remove 3 screws attaching each side of the blower to the rear side of the evaporator.
7. Pull the thermostatic switch temperature sensing tube from the evaporator core.
8. Remove the evaporator core from the unit housing.
9. Position the vaporator core in the unit housing and install the attaching screws and nuts.
10. Insert the thermostatic switch temperature sensing tube in the evaporator core.
11. Connect the expansion valve and the evaporator outlet tube to the evaporator core.
12. Leak test, evacuate, and charge the system (Part 36-30).
13. Install the evaporator cover.
14. Install the screen and covering hood and install the retaining screws.

CONDENSER

1. Discharge the air conditioning system into the garage exhaust system (Part 36-30).
2. Remove the screws which retain the covering hood and remove the hood and screen.
3. Disconnect the condenser inlet (top) pipe from the condenser and cap the fittings (Fig. 5).
4. Remove the 4 housing to cab retaining bolts and washers from inside the cab.
5. Disconnect the drain hose; lift the unit up from the cab and install blocks. **Do not damage the seal around the rubber boot.**
6. Disconnect the condenser outlet line at the underside of the unit housing and cap the fittings.
7. Remove 2 screws from the front of the condenser on each side and remove the condenser.
8. Position the condenser to the front of the unit and install the 4 retaining screws.
9. Connect the inlet and outlet tubes to the condenser.
10. Leak test, evacuate, and charge the system (Part 36-30).
11. Remove the blocks and lower the unit to the top of the cab. Connect the drain hose and install the 4 unit retaining bolts and washers.
12. Install the screen and covering hood and install the retaining screws.

EXPANSION VALVE

1. Discharge the air conditioning system into the garage exhaust system (Part 36-30, Adjustments).
2. Remove the screws which retain the covering hood, and remove the hood and screen.
3. Remove the evaporator cover retaining screws and remove the evaporator cover.
4. Remove the insulation from the expansion valve temperature bulb and remove the bulb clamp (Fig. 4).
5. Disconnect the valve from the evaporator inlet pipes and remove the valve.
6. Connect the valve to the evaporator inlet pipes.
7. Position the temperature bulb to the evaporator outlet pipe and install the clamp and insulation.

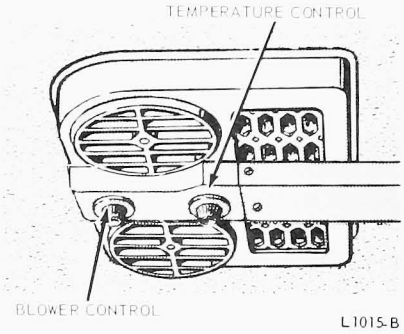

FIG. 3 Air Conditioner Control Panel and Air Registers—C-Series

8. Leak test, evacuate, and charge the system (Part 36-30).
9. Install the evaporator cover.
10. Install the screen and covering hood and install the retaining screws.

RECEIVER TANK AND/OR SIGHT GLASS

1. Discharge the air conditioning system into the garage exhaust system (Part 36-30).
2. Remove the screws which retain the covering hood, and remove the hood and screen.
3. Disconnect the inlet pipe from the top of the receiver and cap the fittings (Fig. 5).
4. Remove the 4 housing-to-cab retaining bolts and washers from inside the cab.
5. Disconnect the drain hose; lift the unit up from the cab and install blocks under the unit. **Do not damage the seal around the rubber boot.**
6. Disconnect the tube from the sight glass and cap the fittings.
7. Remove the 2 U-bolts attaching the receiver to the fan shroud and remove the receiver and sight glass.
8. Remove the sight glass from the receiver tank.
9. Install the sight glass to the receiver tank, making sure it can be seen after installation.
10. Position the receiver and sight glass to the shroud and install the U-bolts.
11. Connect the tube to the sight glass at the lower side of the unit.
12. Connect the tube to the top of the receiver tank.
13. Leak test, evacuate, and charge the system (Part 36-30).
14. Remove the blocks and lower the unit to the top of the cab. Connect the drain hose and install the 4 retaining bolts and washers.
15. Install the screen and covering hood and install the retaining screws.

EVAPORATOR BLOWER AND MOTOR

1. Remove the screws which retain the covering hood, and remove the hood and screen.
2. Remove the evaporator cover retaining screws and remove the evaporator cover.
3. Disconnect the blower motor wires.
4. Remove 2 nuts retaining the blower housing to the unit housing bottom (Fig. 4).
5. Remove 3 screws attaching each side of the blower to the rear side of the evaporator core and remove the blower and motor.
6. Position the blower and motor in the unit housing and install the attaching screws and nuts.
7. Connect the blower motor wires.
8. Install the evaporator cover.
9. Install the screen and covering hood and install the retaining screws.

BLOWER SWITCH

1. Pull the air register down and unhook the spring from the housing.
2. Pull the knob off the blower switch.
3. Remove the switch retaining nut and remove the wires from the switch and remove the switch.
4. Connect the wire to the switch. Install the switch in the opening and install the retaining nut and knob.
5. Position the air register to the opening and hook the spring inside the housing.

CONDENSER OVERHEAT SWITCH

1. Remove the screws which retain the covering hood, and remove the hood and screen.
2. Disconnect the switch wires at the terminal block (Fig. 5).

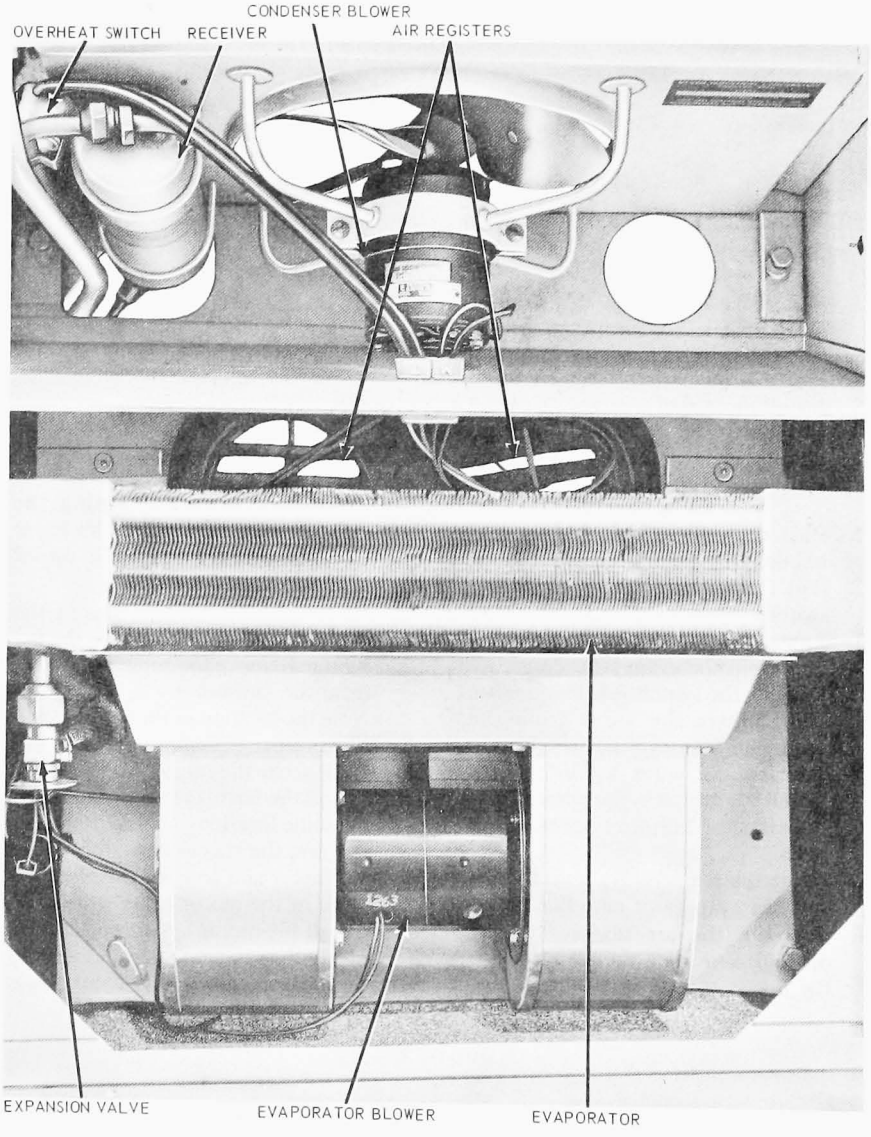

FIG. 4 C-Series Air Conditioner—Hood Removed

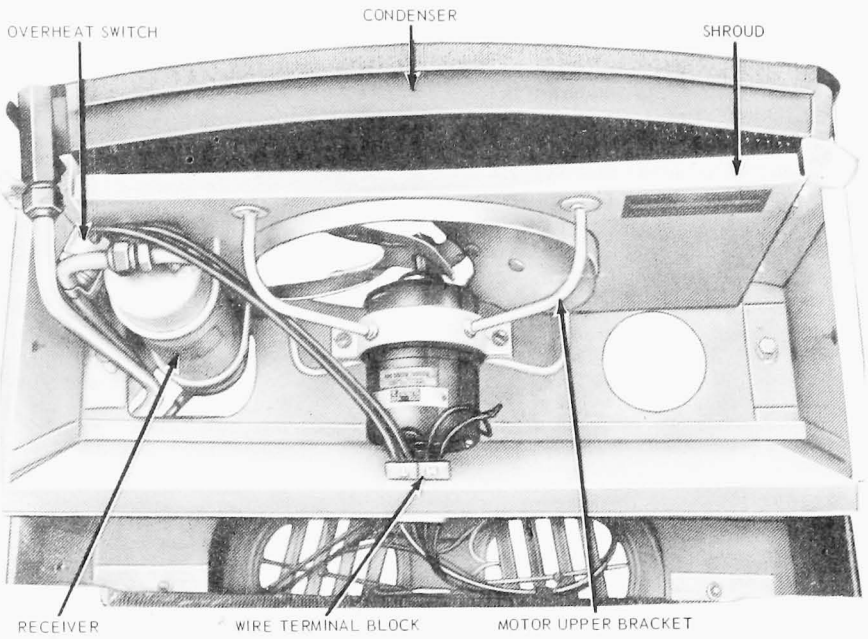

FIG. 5 C-Series Condenser, Receiver and Fan Installation

3. Pull the switch from the receiver outlet tube.
4. Clip the switch to the receiver outlet tube and connect the wires.
5. Install the screen and covering hood and install the retaining screws.

THERMOSTATIC SWITCH

1. Pull the air register down and unhook the spring from the housing.
2. Pull the knob off the thermostatic switch.
3. Remove the temperature sensing tube from the evaporator core.
4. Remove the switch retaining screws and remove the wires from the switch and remove the switch.
5. Connect the wires to the switch. Install the switch in the opening and install the retaining screws and knob.
6. Insert the temperature sensing tube into the evaporator core fins.
7. Position the air register to the opening and hook the spring inside the housing.

CONDENSER FAN MOTOR

1. Remove the screws which retain the covering hood, and remove the hood and screen.
2. Remove the nuts retaining the motor upper bracket to the fan shroud.
3. Remove 2 screws retaining the motor upper bracket to the lower bracket and remove the upper bracket (Fig. 5).
4. Disconnect the motor wires at the connector block and remove the fan motor. Remove the rubber insulator from the fan motor.
5. Note the location of the fan blade on the motor; then, remove the fan blade from the motor.
6. Install the fan blade on the motor in the same location as before removal.
7. Position the rubber insulator on the fan motor and position the motor in place in the motor lower bracket.
8. Install the motor upper bracket and install the retaining nuts and screws.
9. Connect the motor wires and check the operation of the motor and fan.
10. Check the surface of the condenser for accumulation of leaves or other foreign material causing restricted air flow around the condenser fins.
11. Install the screen and covering hood and install the retaining screws.

RELAY AND CIRCUIT BREAKER

A relay and circuit breaker are mounted on the lower lip of the instrument panel to the right of the glove box (Fig. 2).

Remove the two relay mounting bolts, nuts and washers and lower the relay assembly below the panel. Transfer the wires to the new assembly one at a time. Mount the assembly on the instrument panel, installing the black ground wire under the left mounting nut.

PART 36-65 Econoline Air Conditioning System

Applies To Econoline

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION AND OPERATION	65-01	REMOVAL AND INSTALLATION - Cont.	
REMOVAL AND INSTALLATION		Dehydrator-to-Evaporator Hose	65-03
Auxiliary Evaporator	65-04	Evaporator Core	65-02
Blower Motor - Auxiliary Evaporator	65-04	Evaporator-to-Compressor Hose	65-03
Blower Motor - Main Evaporator	65-03	Expansion Valve	65-02
Blower Switch	65-03	Thermostatic Switch	65-03
Condenser and/or Receiver	65-02		
Condenser-to-Compressor Hose	65-04		

This part deals with the controls and components that are peculiar to the Econoline air conditioning system. Part 36-30 gives the information and procedures required for servicing the refrigeration system which is common to all truck lines. Reference to both parts is necessary for complete servicing of the Econoline system.

DESCRIPTION AND OPERATION

The air conditioner used on the Econoline is a recirculating type, separate from the heater.

Controls for the unit are located on the left side panel directly behind the drivers seat (Fig. 1). The controls consist of two sliding levers. The left lever is the temperature control, while the right lever controls the blower motor.

The compressor and condenser assemblies are located at the front of the engine compartment. The evaporator locates against the left frame side rail and is bolted to the underside of the floor (Fig. 1). The evaporator must be serviced from under the vehicle.

Refrigerant hoses are routed from the engine compartment under the floor pan, to the evaporator.

The thermostatic switch is located inside the unit control housing.

The blower motor switch is also located in the control housing.

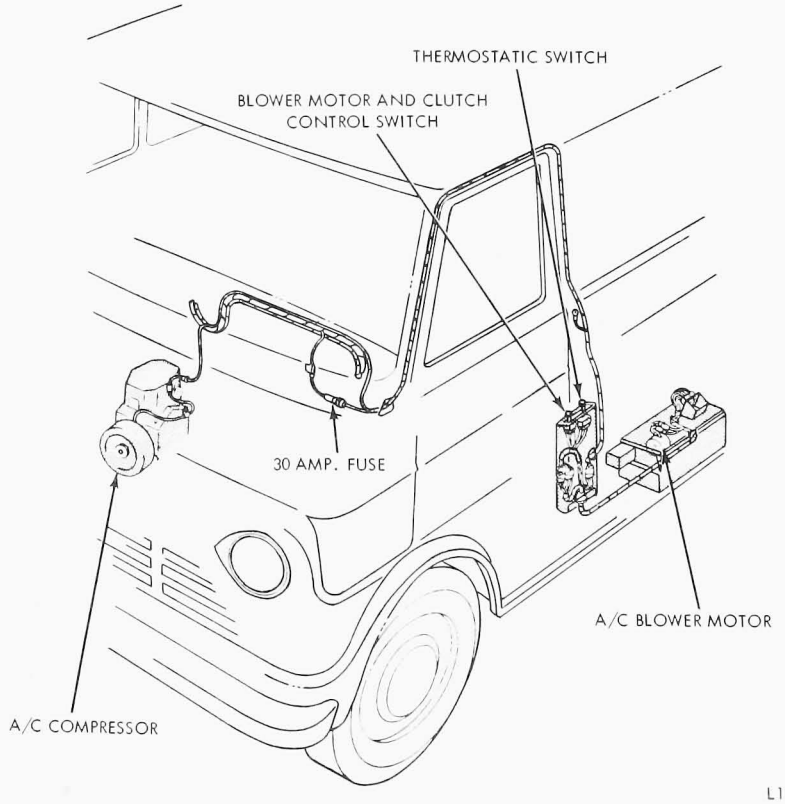

FIG. 1 Econoline Air Conditioner System

REMOVAL AND INSTALLATION

EVAPORATOR CORE

Removal

1. Remove the engine cover.
2. Remove the back seat if the vehicle is so equipped. Pull the carpet or mat out of the way.
3. Remove the control housing cover and disconnect the wiring harness. Tie the harness out of the way.
4. Remove the screws retaining the register to the floor and remove the register (Fig. 2).
5. Position the sensor tube out of the evaporator core.
6. Position a floor jack under the evaporator case and raise the jack until it just contacts the evaporator. Disconnect the hoses at the evaporator.
7. Working inside the vehicle, remove the screws retaining the rear air duct and remove the duct.
8. Remove the 10 bolts retaining the evaporator to the floor pan.
9. Working under the vehicle, remove the front and rear evaporator retaining nuts. Lower the evaporator case on the jack while pulling the wire through the floor pan opening. Remove the evaporator from under the vehicle.
10. Remove the screws retaining the expansion valve cover and remove the cover. Then, remove the cover seal.
11. Remove the gasket from the top of the case.
12. Remove the screws from the top rail which positions the evaporator core to the case. Remove the rail.
13. Remove the insulating tape from the expansion valve and remove the valve from the core.
14. Remove the 4 screws retaining the evaporator core to the case and lift the core out of the case.

Installation

1. Position the evaporator core in the case and install the 4 retaining screws. Then, install the top rail which positions the core in the case.
2. Install the expansion valve and seal. Wrap the valve with insulating tape.
3. Install the expansion valve cover.
4. Position a new gasket on top of the evaporator case (Fig. 2).
5. Position the evaporator case on a jack and raise the case into position against the floor pan. Install the front and rear retaining nuts. Route the wire harness up through the floor pan. Connect the hoses at the evaporator then lower the jack.

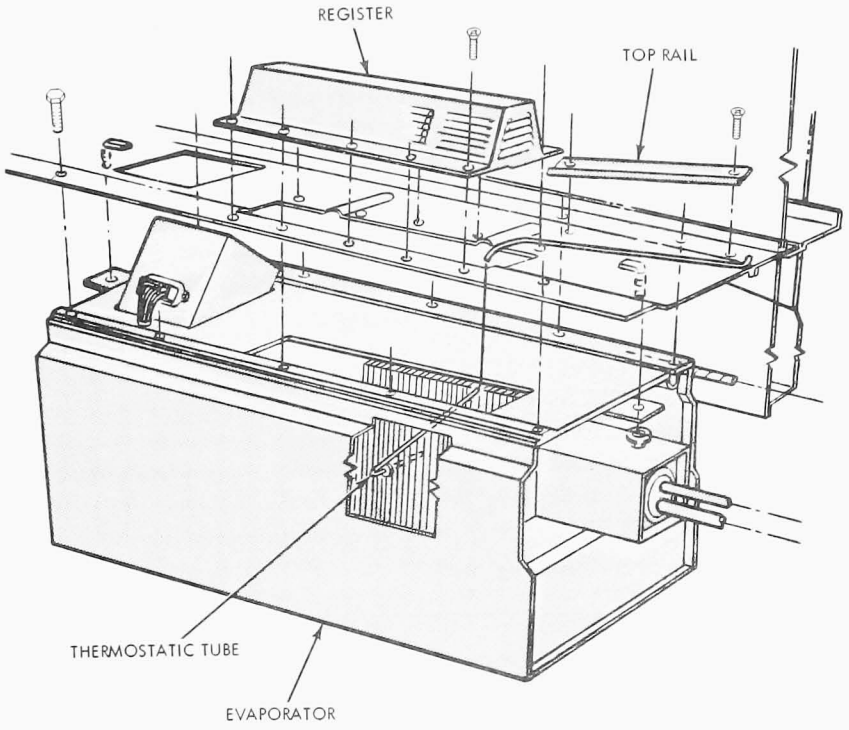

FIG. 2 Evaporator Installation—Econoline

6. From inside the vehicle install the 10 evaporator retaining bolts.
7. Position the sensor tube into the evaporator core.
8. Install the air duct.
9. Install the register.
10. Reposition the carpet and install the rear seat, if equipped.
11. Connect the wires in the control housing and install the cover.
12. Install the engine cover.

CONDENSER AND/OR RECEIVER TANK

Removal

1. Open the hood and remove the hood lock assembly mounting bracket.
2. Disconnect both lines at the condenser and receiver tank and position the lines out of the way.
3. Remove the 4 bolts retaining the condenser assembly to the radiator and lift the condenser out of the vehicle.
4. If the receiver tank is to be replaced, remove it from the condenser assembly.

Installation

1. If the receiver tank has been removed from the condenser, install the receiver.
2. Position the condenser assembly on the radiator and install the 4 retaining bolts.
3. Connect the lines at the condenser and receiver tank.
4. Install the hood lock mounting bracket.

EXPANSION VALVE

Removal

1. Raise the vehicle on a hoist.
2. If the vehicle is equipped with an auxiliary heater, disconnect the 2 heater hoses and allow the coolant to drain into a pan.
3. Remove the 4 nuts retaining the auxiliary heater to the floor and push the heater up and out of the way.
4. Disconnect the two hoses at the expansion valve.
5. Remove the expansion valve cover and seal from the evaporator.
6. Unwrap the insulating tape from the expansion valve.
7. Remove the expansion valve from the evaporator.

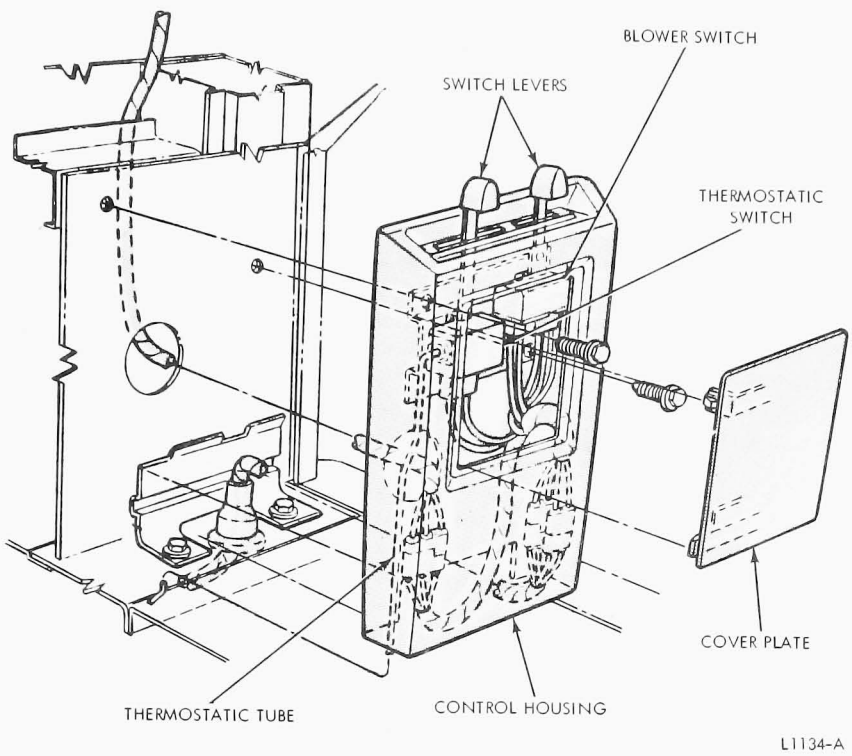

FIG. 3 Air Conditioner Control Housing—Econoline

Installation
1. Install the expansion valve to the evaporator.
2. Wrap the expansion valve with insulating tape.
3. Install the expansion valve cover and seal on the evaporator.
4. Connect the lines to the expansion valve.
5. If the vehicle is equipped with an auxiliary heater, position the heater against the floor pan and install the retaining nuts.
6. Connect the auxiliary heater hoses.
7. Lower the vehicle and add coolant as required.

BLOWER MOTOR

Removal
1. Remove the evaporator and core from the vehicle following the procedure outlined previously in this section.
2. Disconnect the blower motor wires.
3. Remove the 4 retaining screws and remove the blower motor assembly from the case.

Installation
1. Position the blower motor in the case and install the retaining screws.
2. Connect the blower motor wires.
3. Install the evaporator core and evaporator assembly in the vehicle as outlined previously in this section.

THERMOSTATIC SWITCH

Removal
1. Position the carpet or mat out of the way.
2. Remove the evaporator register from the floor pan.
3. Position the sensor tube out of the evaporator core.
4. Remove the control housing cover (Fig. 3).
5. Remove the Allen screw that retains the switch lever to the switch and remove the lever.
6. Disconnect the wires to the thermostatic switch and remove the retaining screw. Remove the switch and tube assembly.

Installation
1. Position the switch and tube assembly in the housing. Route the sensor tube into the evaporator core. Connect the switch wires and install the retaining screw.
2. Install the switch lever.
3. Install the control housing cover.
4. Install the register in the floor.
5. Reposition the carpet or mat.
6. Check the operation of the blower.

BLOWER SWITCH

Removal
1. Remove the control housing cover.
2. Remove the Allen screw retaining the switch lever to the blower switch and remove the lever (Fig. 3).
3. Disconnect the wires at the blower switch.
4. Remove the blower switch retaining screw and remove the switch.

Installation
1. Position the blower switch in the control housing and install the retaining screw.
2. Connect the switch wires.
3. Install the switch lever.
4. Install the control housing cover.

DEHYDRATOR-TO-EVAPORATOR HOSE

Removal
1. Remove the engine cover and the air cleaner.
2. Discharge the air conditioning system (Part 36-30, Adjustments).
3. Raise the vehicle on a hoist.
4. Remove the clamp retaining the hoses at the condenser (Fig. 4). Disconnect the hose at the receiver tank.
5. Remove the 2 strap retainers and hose clamp, from inside the engine compartment.
6. Working under the vehicle remove the strap retainers and hose clamps. Remove the hose from the evaporator clamp, and remove the hose from the vehicle.

Installation
1. Position the new hose in the vehicle and route the hose properly (Fig. 4).
2. Connect the hose at the evaporator.
3. Position the hose in the hose clamps and install the clamps on the underside of the vehicle. Also install the strap retainers.
4. Connect the hose at the receiver tank.
5. Position the hoses in the hose clamps and install the clamps. Also install the strap retainers.
6. Install the air cleaner.
7. Leak test, evacuate and charge the air conditioning system (Part 36-30, Adjustments).
8. Install the engine cover.

EVAPORATOR-TO-COMPRESSOR HOSE

Removal
1. Remove the engine cover and the air cleaner.
2. Raise the vehicle on a hoist.
3. Discharge the air conditioning system (Part 36-30, Adjustments).

4. Disconnect the hose at the service valve on the compressor.
5. Remove the hose clamps and strap retainers from inside the engine compartment.
6. Working under the vehicle, remove the hose clamps and strap retainers.
7. Disconnect the hose at the evaporator and remove the hose from the vehicle.

Installation

1. Position the hose in the vehicle and route the hose properly.
2. Connect the hose at the evaporator.
3. Install the hose clamps and strap retainers on the underside of the vehicle.
4. Connect the hose to the service valve on the compressor.
5. Install the hose clamps and strap retainers.
6. Leak test, evacuate and charge the air conditioning system.
7. Install the air cleaner and the engine cover.

CONDENSER-TO-COMPRESSOR HOSE

Removal

1. Remove the engine cover and the air cleaner.
2. Discharge the air conditioning system (Part 36-30, Adjustments).
3. Remove the hose at the condenser.
4. Disconnect the hose at the condenser.
5. Remove the hose from the service valve on the compressor.

Installation

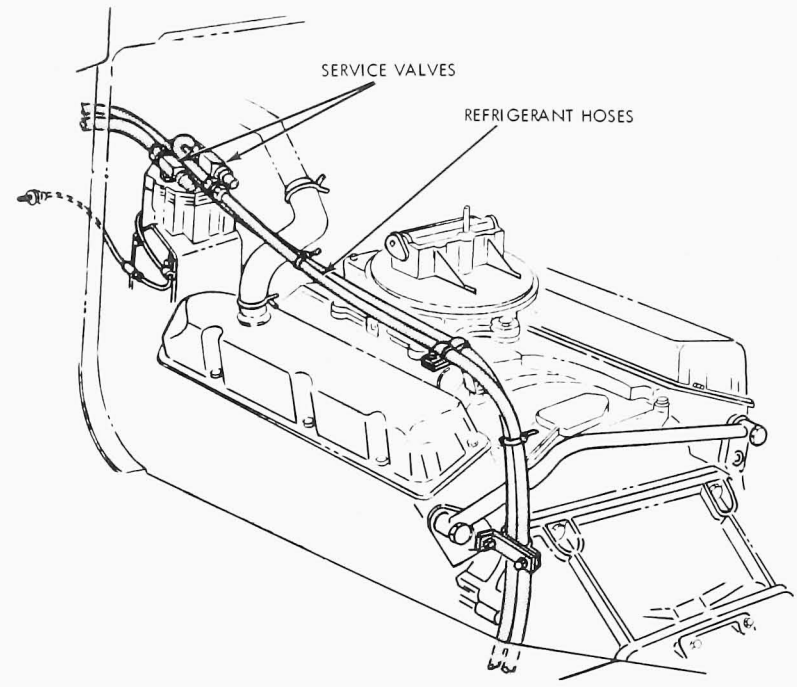
1. Position the hose in the vehicle and connect the hose to the service valve on the compressor.
2. Connect the hose at the condenser.
3. Install the hose clamps at the condenser.
4. Leak test, evacuate and charge the air conditioning system (Part 36-30, Adjustments).
5. Install the air cleaner and the engine cover.

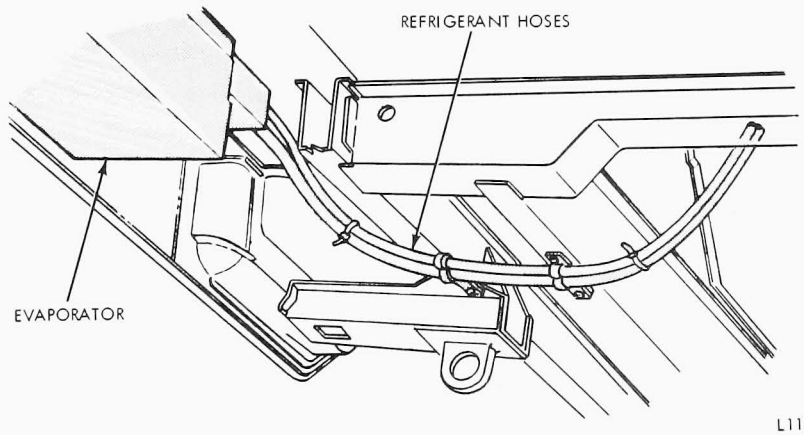
AUXILIARY EVAPORATOR ASSEMBLY

The auxiliary evaporator is located inside the body under the first bench seat on all A/C equipped bus models. On van models, it is mounted forward of the left rear wheel housing.

Both the main evaporator and the auxiliary evaporator are operated by the same control levers.

1. Remove the bench seat.
2. Raise the vehicle, and install safety stands.





L1132-A

FIG. 4 Refrigerant Hose Routing—Econoline

3. From under the vehicle, disconnect the wiring harness at the connector, and the suction and liquid lines at the quick disconnect fitting (Fig. 5).

Bleed off refrigerant pressure before disconnecting the liquid and suction lines.

4. Remove the four washer-head type nuts that retain the evaporator to the floor pan.
5. Remove the safety stands, lower the vehicle, and remove the evaporator assembly from inside the vehicle.
6. After installing the evaporator, check all fittings and connections for tightness and recharge the system as outlined in (Part 36-30, Adjustments).

BLOWER MOTOR AND FAN ASSEMBLY—AUXILIARY EVAPORATOR

The blower motor and fan assembly can be removed and replaced without removing the auxiliary evaporator assembly from the vehicle.

1. Remove the bench seat.
2. Remove the four evaporator cover retaining screws, and remove the cover from the case.
3. Disconnect the blower motor leads, remove the two motor retaining bolts and nuts from the motor support, and lift the motor assembly from the evaporator housing.

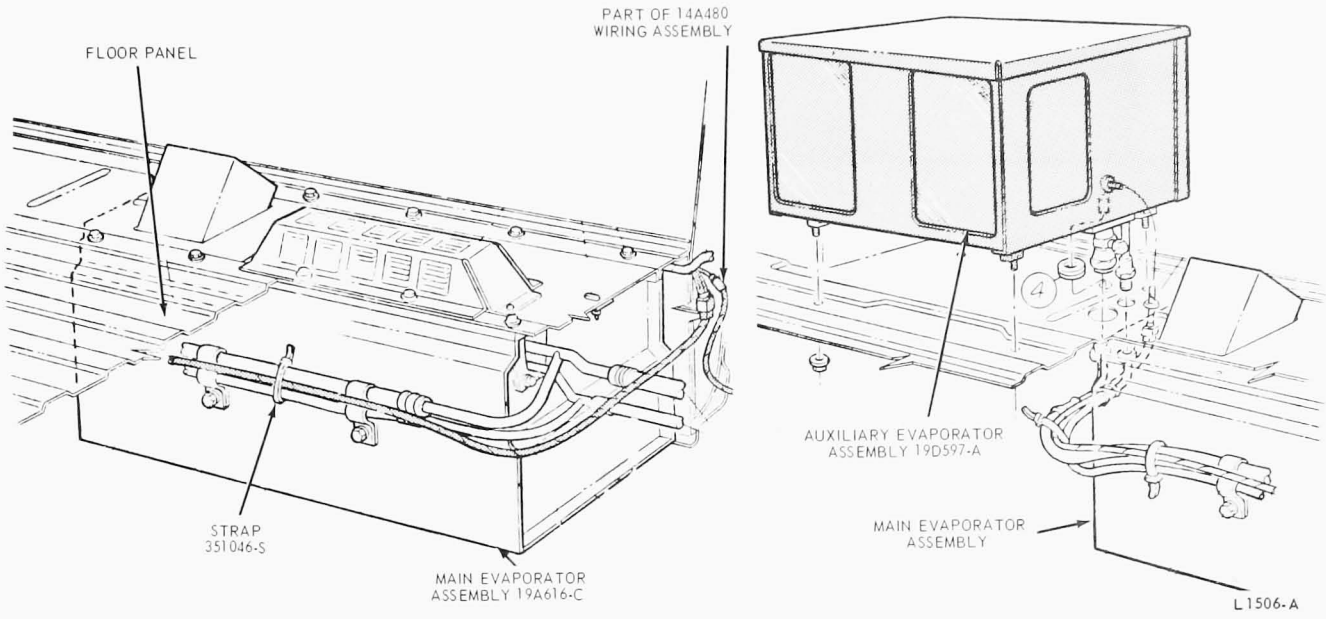


FIG. 5 Dual Evaporator Installation—Econoline

PART 41-01 Seat Tracks — Manual

ADJUSTMENTS

TIE ROD

Tie rod adjustment will affect only the passenger side of the seat. In case the latch retaining the track fails to release, turn the adjusting turnbuckle (Fig. 1), clockwise enough to shorten the tie rod travel and release the track latch. If the latch fails to secure the seat travel, turn the adjusting turnbuckle counterclockwise enough to allow the latch to snap into locking position.

SEAT BACK—ANGLE

C-SERIES

Loosen the stop bolt lock nuts (Fig. 2). Slide the bolt through the bracket on the seat cushion to obtain the desired seat back angle. Then, tighten the lock nuts against the seat cushion bracket. Adjust both stop bolts the same amount to avoid twisting the seat back frame.

REMOVAL AND INSTALLATION

SEAT TRACK—MANUAL BENCH TYPE

F-100-750 AND L-AND W-SERIES

Removal

1. Remove the seat track-to-floor pan retaining screw and washer assemblies three on each side and lift the seat and track assembly out of the vehicle. See Figure 3.
2. Disconnect the seat track latch tie rod from the latches on the seat tracks.
3. Remove the seat track-to-seat cushion (screw and washers) and remove the tracks from the cushion.

Installation

1. Lubricate the seat track assemblies. Assemble the seat tracks to the cushion assembly with the anti-squeak pads (and spacers if so equipped) fitting over the studs between the track and cushion (Fig. 3). Install the track-to-cushion screw and washers and tighten to specification (see Specifications Section).
2. Connect the tie rod to the latch on each seat track.
3. Lift the seat and track assembly into the cab and secure it to the floor pan

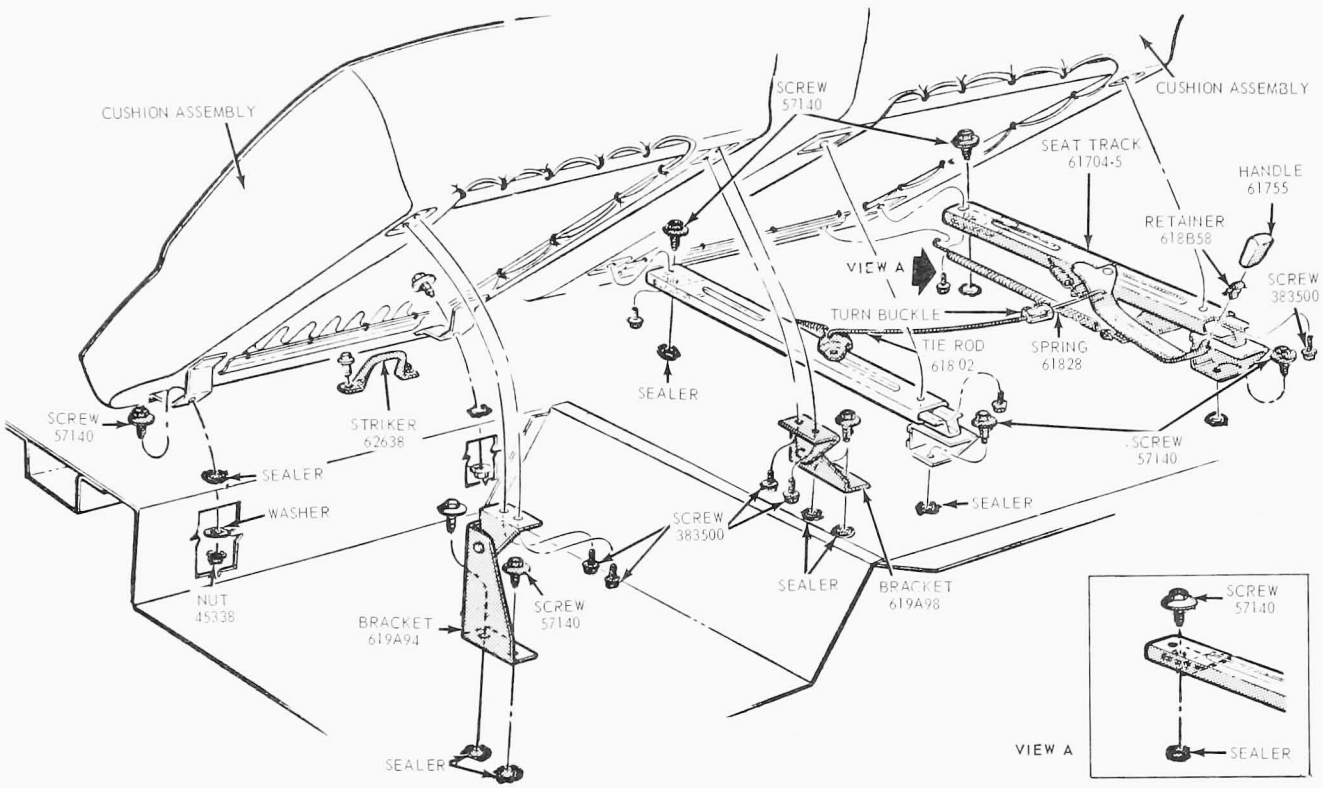

FIG. 1 Bronco Seat and Track Installation

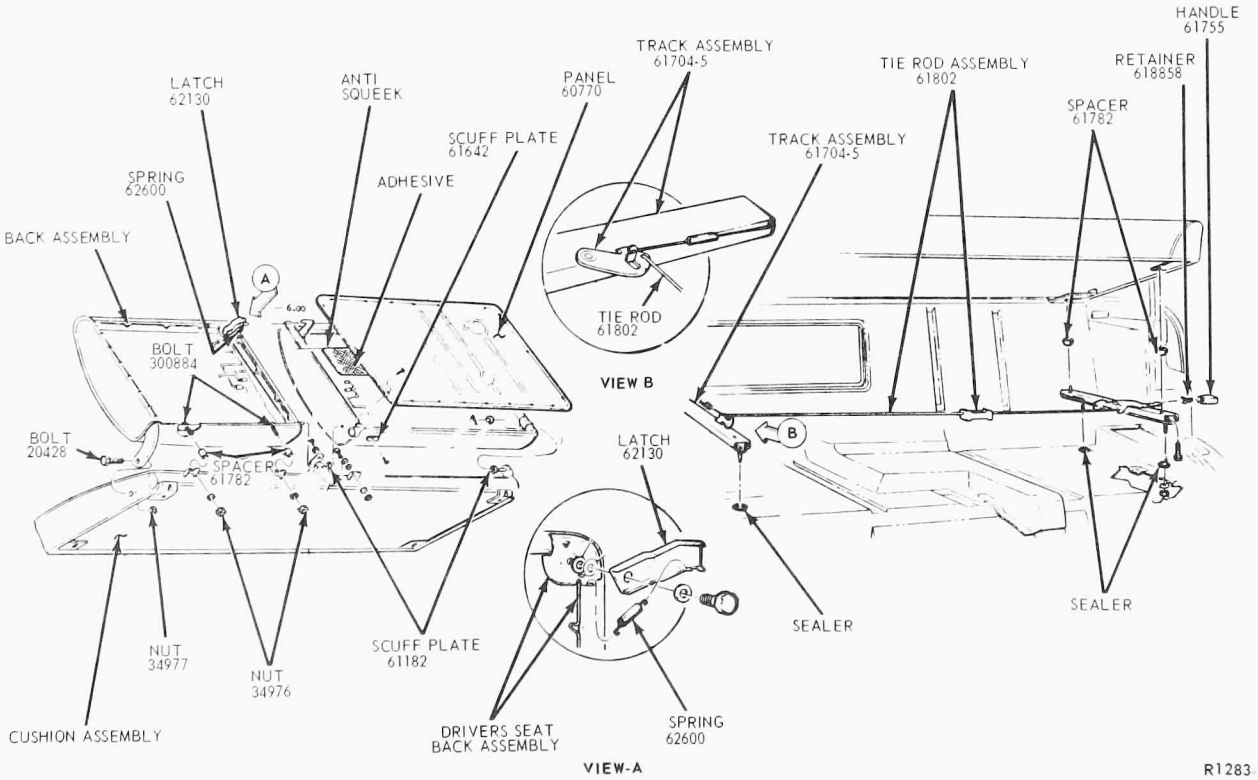
R1509-C



R1283-C

FIG. 2 Seat Back and Track Installation—C-Series

with the retaining screw and washer assemblies. Tighten the screws to specifications (see Specifications in this Part).

C-SERIES

Removal

1. Remove two seat track-to-floor pan retaining nuts and washers from each track (Fig. 2).
2. Lift the seat up to free the seat track studs from the floor pan, and then remove the seat and track assembly from the vehicle.
3. Disconnect the latch spring from the latch on the right seat track assembly and disconnect the latch tie rod from the latch (Fig. 2).
4. Remove the two right seat track-to-cushion screw and washer assemblies and remove the track from the cushion.
5. Separate the tie rod from the adjuster handle on the left track. Remove the two left track-to-cushion screw and washer assemblies and remove the track and adjuster handle assembly from the cushion.

Installation

1. Position the left seat track to the cushion with the anti-squeaks and spacers between the track and cushion. Position the retaining nut on the upper side of the cushion frame front support, install the two retaining screw and washer assemblies, and tighten to specification (see Specifications in this Part).
2. Connect the latch tie rod to the latch on the right track and insert the opposite end of the rod into the hole in the adjuster handle on the left track, and then position the right track to the cushion with the anti-squeaks and spacers between the track and cushion.
3. Position the right seat track and cushion. Position the retaining nut on the upper side of the cushion frame front support, install the two retaining screw and washer assemblies, and tighten to specification (see Specifications in this Part).
4. Lift the seat and track assembly into the cab and position it so that the track studs enter their proper holes in the floor pan.
5. Install the four track-to-floor pan washers and retaining nuts, and tighten to specification (see Specifications in this Part).

SEAT TRACK—BUCKET TYPE

BRONCO

Removal

1. Move the seat to the forward position and remove the screws and washer attaching the rear of each track to the floor pan (Fig. 1).
2. Remove the screws and washer attaching the front end of the seat tracks to the floor pan and remove the seat and track from the vehicle.
3. Disconnect the assist spring from the seat and track.
4. Remove four screws attaching the tracks to the seat frame and separate the tracks from the seat frame.

Installation

1. Position the seat tracks to the seat frame and install the four attaching screws. Tighten to specification in this section.
2. Connect the tie rod to the seat tracks and the assist spring to the seat frame and track (Fig. 1).
3. Place a small amount of sealer around the seat track front and rear attaching holes and position the seat track in the vehicle.

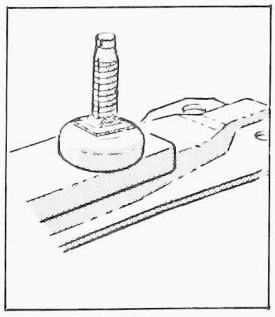
F-500 THROUGH F-750



VIEW B

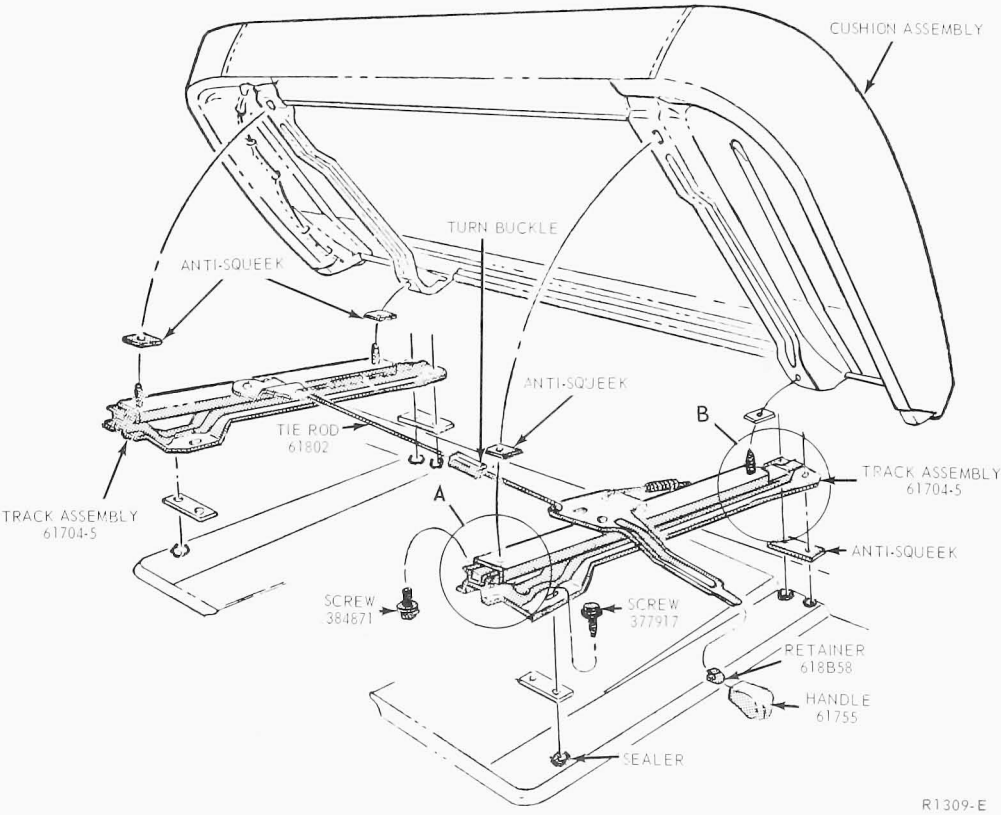


FIG. 3 Bench Seat and Track Installation—F-100 through 750 Series, Typical of L-and W-Series

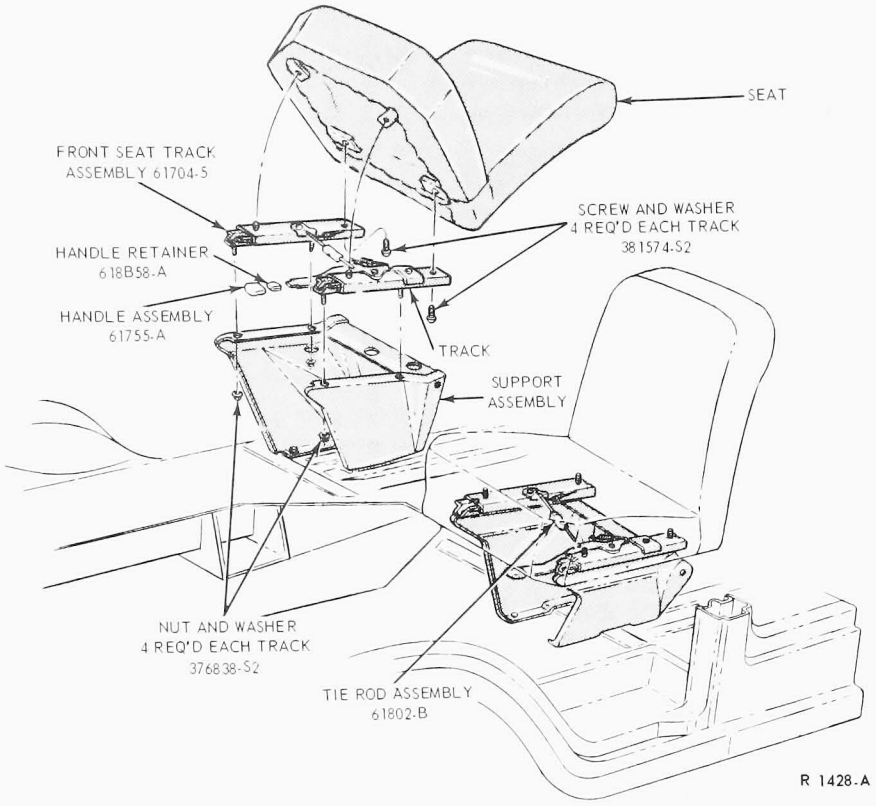

FIG. 4 Bucket Seat and Track Installation—Econoline

4. Install the screws and washer seat track-to-floor.
5. Tighten to specification in this section.

ECONOLINE

Removal

This procedure applies to both right and left front seats.

1. Remove the seat track-to-support nuts and lift the seat and track assembly from its support (Fig. 4).
2. If either seat or track is being replaced, remove the track-to-seat screws and separate the seat from the track.
3. If only the seat is being replaced, proceed to step 1, under Installation. If only the track is being replaced, loosen the turnbuckle and detach the tie rod from the bracket on the right track and the release lever on the left track. Remove the handle assembly and retainer from the lever. Remove the small spring from each track and remove the assist spring. Transfer all these parts to the replacement track.

Installation

1. Position the track assembly to the seat and secure it with the attaching screws and washers. Tighten to specification (see Specifications in this Part).
2. Position the seat and track assembly on the support assembly and secure it with the attaching nuts and washers. Tighten to specifications in this part.

FOLD-DOWN FRONT PASSENGER SEAT

ECONOLINE

The fold-down seat is attached to the support assembly with six nuts. The support assembly is attached to the floor pan with three screws and washers. The rear latch striker is attached to the floor pan with two screws and washers. Tighten all bolts and nuts securely (Fig. 5).

Applies To Bronco and Econoline

REMOVAL AND INSTALLATION

SEAT CUSHION AND BACK ASSEMBLY

BRONCO

The rear seat cushion and back assembly is attached to the floor with four retaining bolts (Fig. 1). When installing the seat assembly to the floor, tighten the retaining bolts to 7-12 ft-lb.

ECONOLINE

The rear seat and cushion assemblies are attached to the floor pan as shown in Fig. 2. When installing the seat assembly to the floor, tighten the attaching bolts to 25-45 ft-lb.

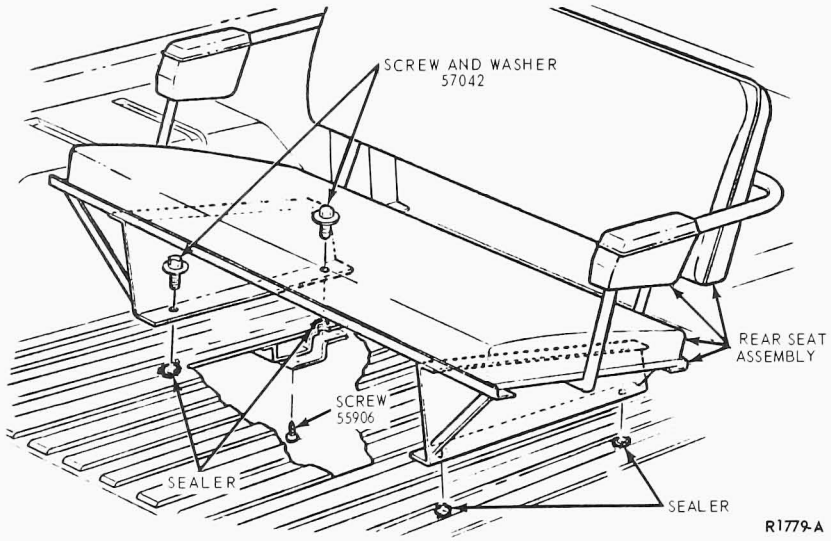

FIG. 1 Rear Seat Cushion and Back Assembly—Bronco

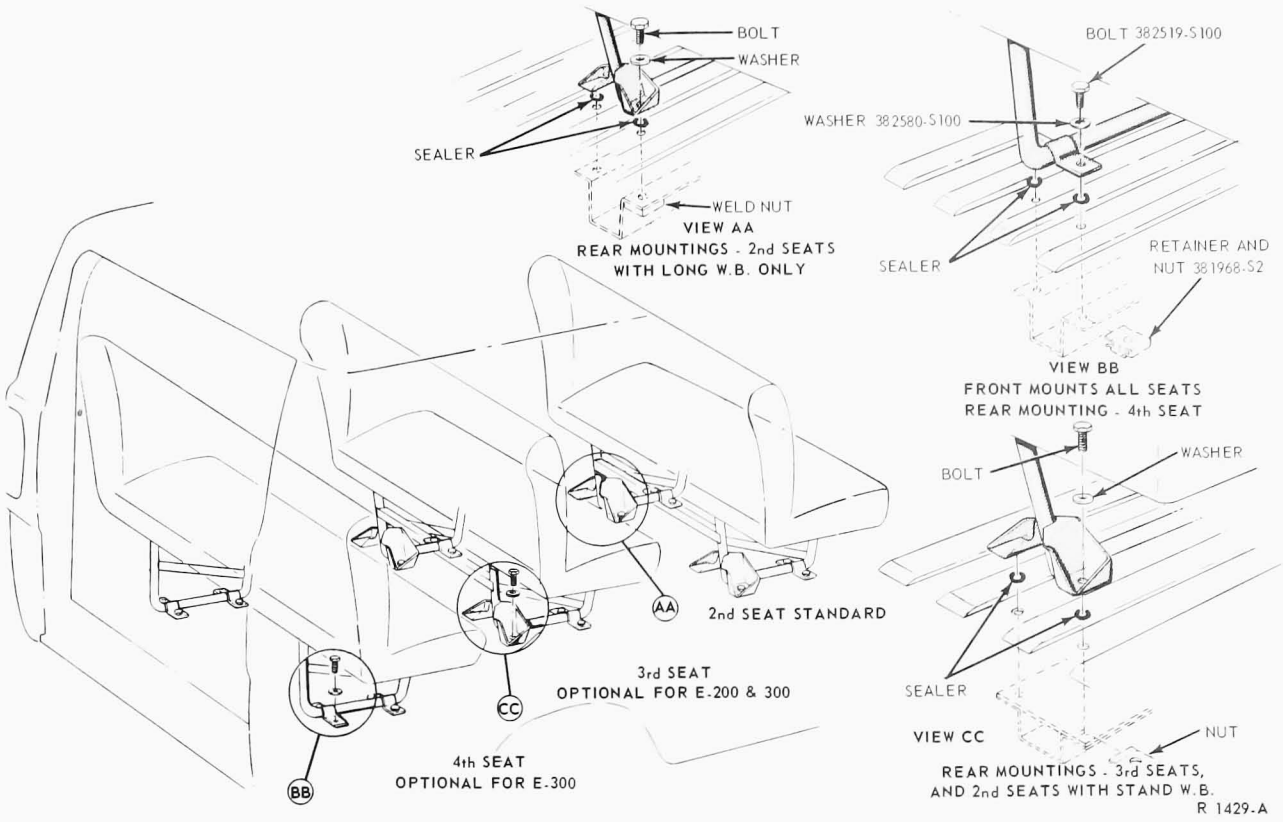

FIG. 2 Rear Seat Cushion and Back Assemblies—Econoline

PART 41-25 Seat Back Latch

GENERAL INFORMATION

SEAT BACK LATCH

All folding front seats have a latch designed to hold the seat back in the normal position. For rear seat passenger entry and exit (Bronco), and to gain access to the storage compartment (F-Series), a handle on the side of the seat back releases the seat back latch.

If the seat back will not latch in position or the latch mechanism will not unlock, it may be necessary to remove the side shield and/or remove the seat back trim cover far enough to inspect the latch mechanism. Then replace any damaged parts to put the latch system in proper working order (Fig. 1 and 2).

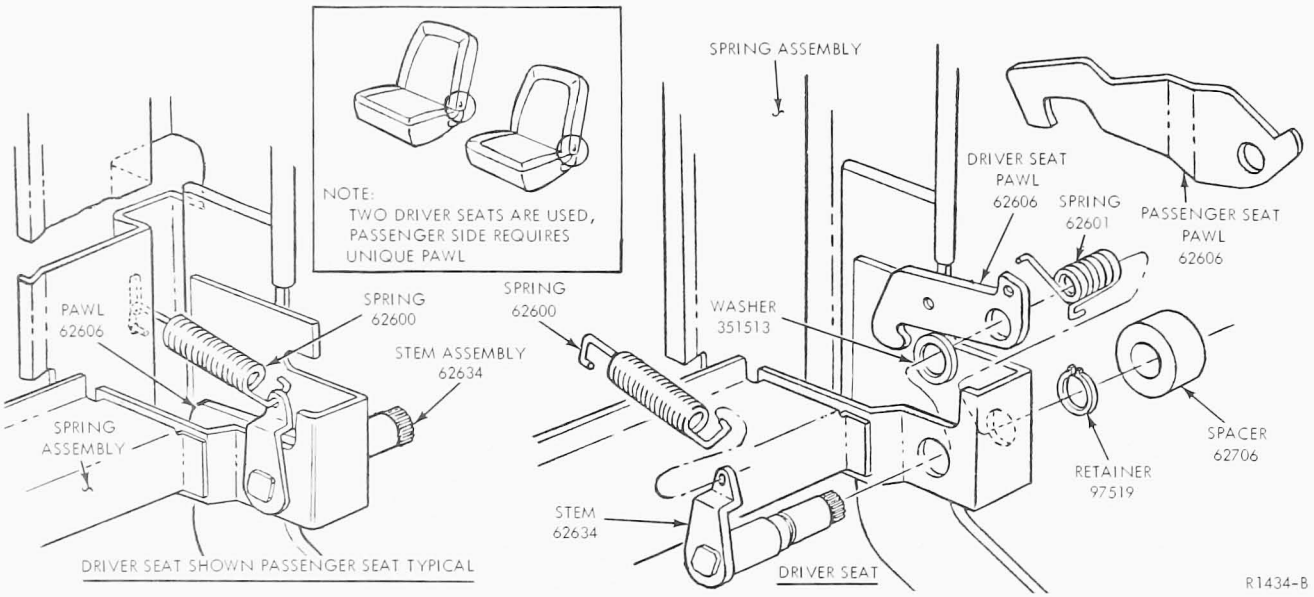

FIG. 1 Seat Back Latch Installation—Bronco

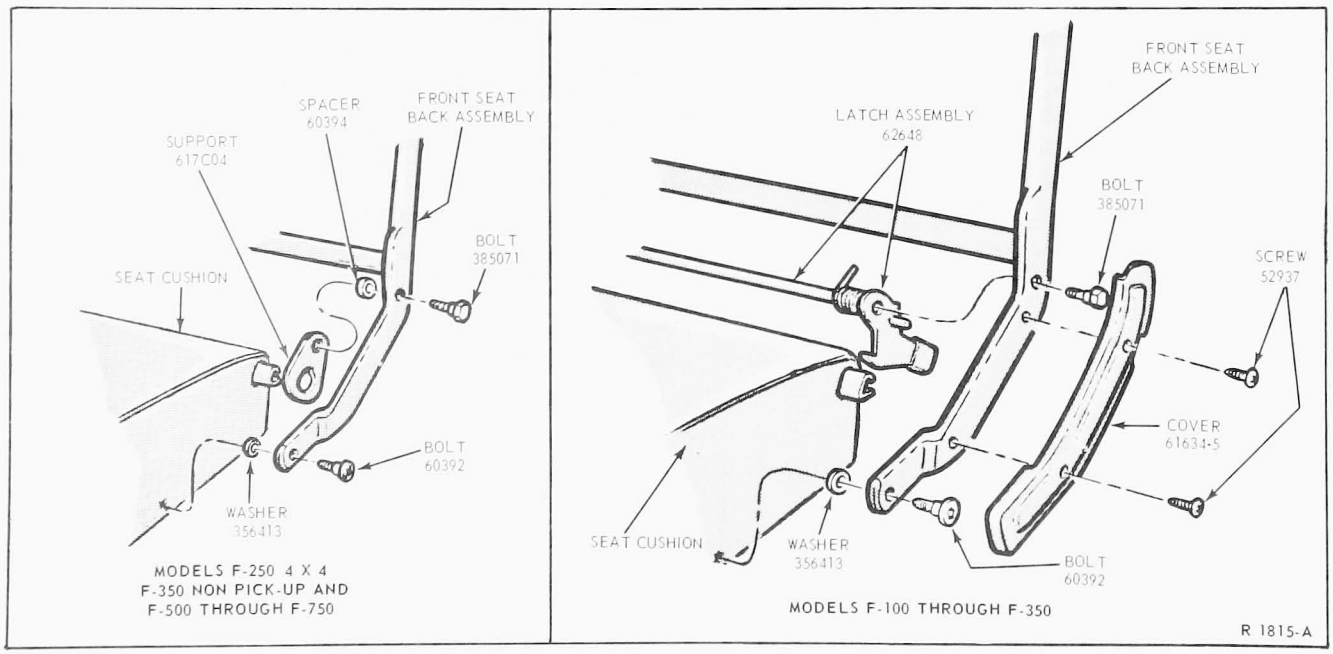

FIG. 2 Seat Back Latch Installation—F-Series

PART 41-50 Seat and Shoulder Belts

COMPONENT INDEX	Page	COMPONENT INDEX	Page
CLEANING	50-06	MAJOR REPAIR OPERATIONS	50-05
GENERAL INFORMATION	50-01	REMOVAL AND INSTALLATION	50-05
		SPECIFICATIONS	50-06

GENERAL INFORMATION

SEAT AND SHOULDER BELTS

The seat belts and shoulder belts are factory installed in their proper locations. If the seat belts or shoulder belts are removed for any reason, they should be installed as shown in figs. 1 through 8. Sealer should be placed around all seat anchor bolt holes in the floor pan. Tighten the anchor bolts to the specification shown in this Part.

Belt assemblies must be installed in matched sets as received and must not be interchanged between vehicle models. The position of inboard front seat belts at the tunnel shall be pointing in a forward direction, plus or minus 15 degrees to the horizontal-all vehicle lines. All other seat belt installations not specifically dimensioned (except those specifically designed to rotate), shall be positioned pointing in a forward direction parallel to the centerline of the vehicle plus or minus 15 degrees.

If a component portion (buckle portion, retractor portion, etc.) of a seat belt or shoulder belt assembly is non-functional or damaged, the entire assembly (buckle, tongue and shoulder belt portions) must be replaced. The replacement assembly must be installed as a matched set and the identification labels on all portions must bear exactly the same code, date of manufacture and manufacturer's name. **Under no circumstances are seat belt or shoulder belt components to be replaced as individual components.** Tool T70P-2100-A is used to remove all round seat and shoulder belt bolts.

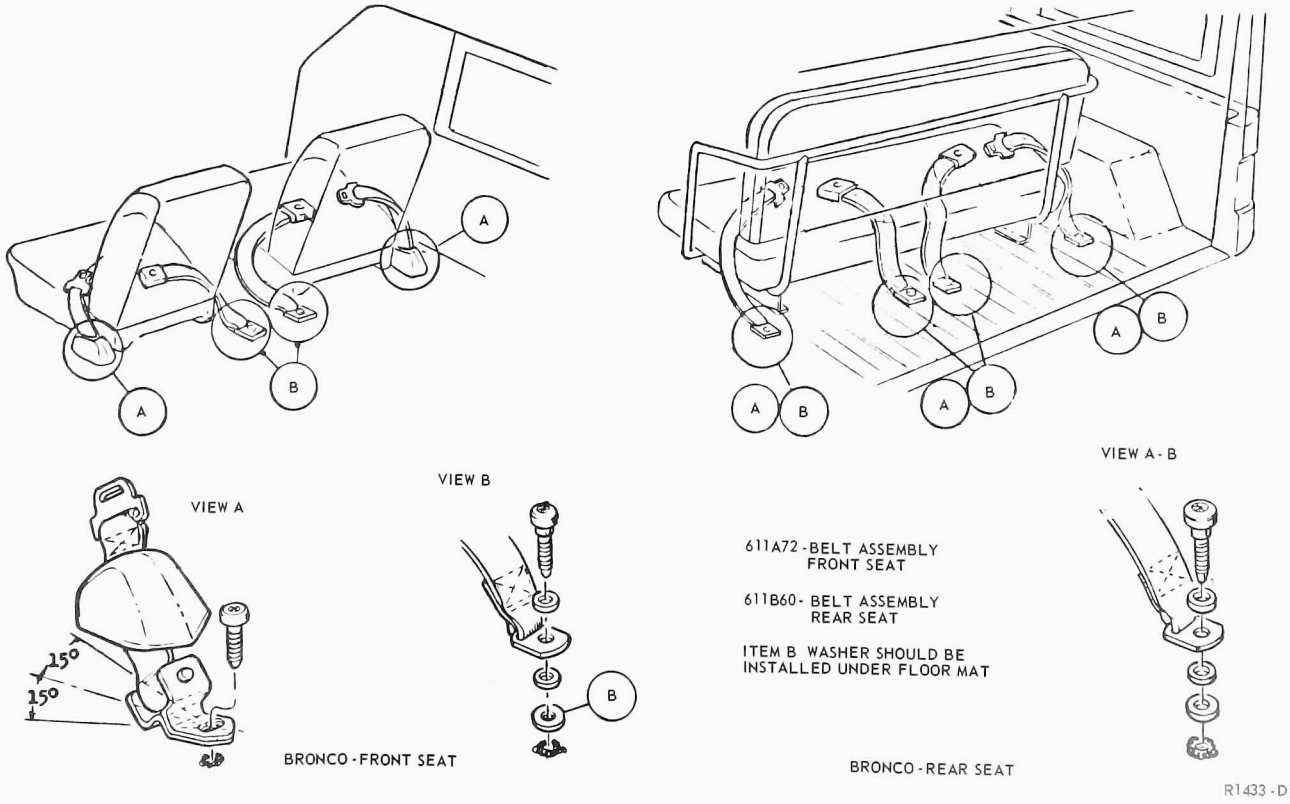

FIG. 1 Seat Belt Installation—Bronco

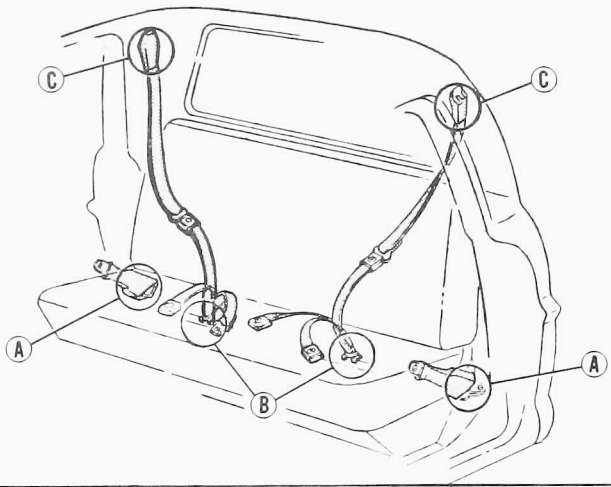

IN STOWAGE POSITION, SHOULDER STRAP (ITEM 1) IS FOLDED APPROXIMATELY IN HALF, TONGUE (ITEM "X") IS INSERTED INTO BOOT AND SECURED WITH ADHESION PADS (ITEM "Y"). SEE VIEW C.

REMOVAL AND INSTALLATION

SEAT AND SHOULDER BELTS

The seat belts and shoulder belts are factory installed in their proper locations. If the belts are removed for any reason, they should be installed as shown in Figs. 1 through 8, as shown on the illustration. Sealer should be placed around all seat belt anchor bolt holes in the floor pan. Tighten the anchor bolts to sepcification as shown at the end of this Part.

MAJOR REPAIR OPERATIONS

SEAT BELT WITH NO ANCHOR PLATE THREAD DAMAGE

1. Remove the damaged bolt from the anchor reinforcement and discard.
2. Install a new bolt with the same part number as indicated in the Specifications section and tighten to specification.

SEAT BELT WITH DAMAGED ANCHOR PLATE THREADS

1. Remove the broken or stripped bolt and discard.
2. Drill out the internal threads in the anchor plate with a 27/64 inch drill.
3. Re-thread the anchor plate with a 1/2-13 tap.
4. Blow out the chips.
5. Install the attachment parts in the sequence shown in Figs. 1 through 8, whichever is applicable. Tighten the replacement bolt to specification as shown in the Specifications section in this Part. Original parts are to be replaced with the repair parts indicated in the seat belt parts replacement charts, Specifications section. Unless specified in the chart, use original parts.

SHOULDER BELT WITH DAMAGED ANCHOR PLATE THREADS

1. Remove the broken or stripped bolt and discard.
2. Drill out the internal threads in the anchor plate with a 13/32 inch drill.
3. Blow out the chips.
4. Install the attachment parts in the sequence shown in Figs. 1 through 8,

whichever is applicable. Tighten the replacement bolt (7/16-32) to specification shown in the Specifications section in this Part.

Original parts are to be replaced with the repair parts indicated in the seat belt parts replacement charts, Specifications section. Unless specified in the chart, use original parts.

CLEANING

SEAT AND SHOULDER BELTS

The belt webbing can be cleaned with any mild soap solution recommended for cleaning upholstery or carpeting and following the instructions provided with soap. **Bleaching and redying of the belt webbing is not recommended because of deterioration which may be caused to the webbing.**

Inspect for loose, cut or damaged webbing.

PART 41-60 Seat Trim

GENERAL INFORMATION

SEAT TRIM

The following seat trim removal and installation procedures generally apply to all truck lines. If some of the steps do not apply to the particular vehicle being serviced, proceed to the next step and review the appropriate illustration shown.

Unless otherwise noted, the illustrations shown in this section are **typical of all bucket and bench seat assemblies.** See Figs. 1 through 6.

Seat trim replacement requires removal and installation of seat components such as seat assemblies, track assemblies and seat belts. Refer to the applicable part in Group 41 for these procedures.

REMOVAL AND INSTALLATION

SEAT CUSHION AND BACK COVER—BUCKET SEAT

BRONCO AND ECONOLINE

Repairs to seat cushions or seat backs are performed out of the vehicle and are usually limited to replacement of torn or burned seat covers. In a few instances, the pads may be damaged and require replacement.

When installing a new seat or back cover assembly, refer to Figs. 1 and 2 for the location of listing wires, hog rings, anti-squeak pads, and seat pad stack-up.

1. Remove the seat belt retainer loop (if so equipped), one screw. Remove the seat and track assembly if the cushion cover is to be replaced (Group 41).
2. Remove the seat tracks from the seat.
3. Remove the seat back assembly (Fig. 1) and the seat cushion stops.
4. Remove the hog rings retaining the seat cushion cover to the frame and remove the cover.
5. Remove the back cushion stops and the seat back release handle.
6. Remove the seat back panel assembly (retained with clips).
7. Remove the hog rings retaining the seat back cover to the frame and remove the cover.
8. Transfer the bolster wires to the cover listings.
9. Position the seat cushion cover to the seat and install the hog rings as shown in Figs. 1 and 2. Install the seat cushion stops.
10. Position the seat back assembly and install the hog rings (Figs. 1 and 2).
11. Install the seat back stops, release handle and rear seat back panel assembly. Then, install the seat back to the seat cushion assembly.
12. Install the seat tracks to the seat cushion and tighten to specification shown in Group 41, Specifications section.
13. Install the seat assembly into the vehicle. Tighten to specification shown in Group 41, Specifications section. Install the seat belt retainer loop (if so equipped), one screw.

SEAT CUSHION COVER—BENCH SEAT

F AND L-SERIES

1. Remove the seat and track assembly from the vehicle. (Group 41).
2. Remove the seat back assembly (Figs. 3, 4 and 5) from the seat cushion.
3. Cut the hog rings retaining the cushion cover to the frame assembly and remove the cover.
4. Transfer the listing wires from the old cover to the listings in the new cover.
5. Position the cover over the spring assembly and fasten the cover with hog rings.
6. Install the seat back to the seat cushion.
7. Install the seat and track assembly into the vehicle and tighten the attaching screws and washers shown in Group 41, Specifications section.

SEAT BACK COVER—BENCH SEAT

F AND L-SERIES

1. Remove the seat back-to-cushion mounting bolts and washers. Separate the back from the cushion and lift the seat back out of the vehicle.
2. Cut the hog rings attaching the cover to the seat back or cushion spring assembly (Figs. 3, 4 and 5) and remove the seat back cover.
3. If the padding is being replaced, cut the hog rings that attach the padding to the spring assembly and remove the padding.
4. Position the new pad to the seat back assembly and fasten it in place with hog rings.
5. Transfer the listing wires from the old cover to the listings in the new cover.
6. Position the new cover over the padding, pull the cover tight, and fasten the cover to the spring assembly with hog rings.
7. Install the seat back to the seat cushion assembly.

SEAT BACK—LEFT SIDE

C-SERIES

1. Remove the seat and track assembly from the cab.

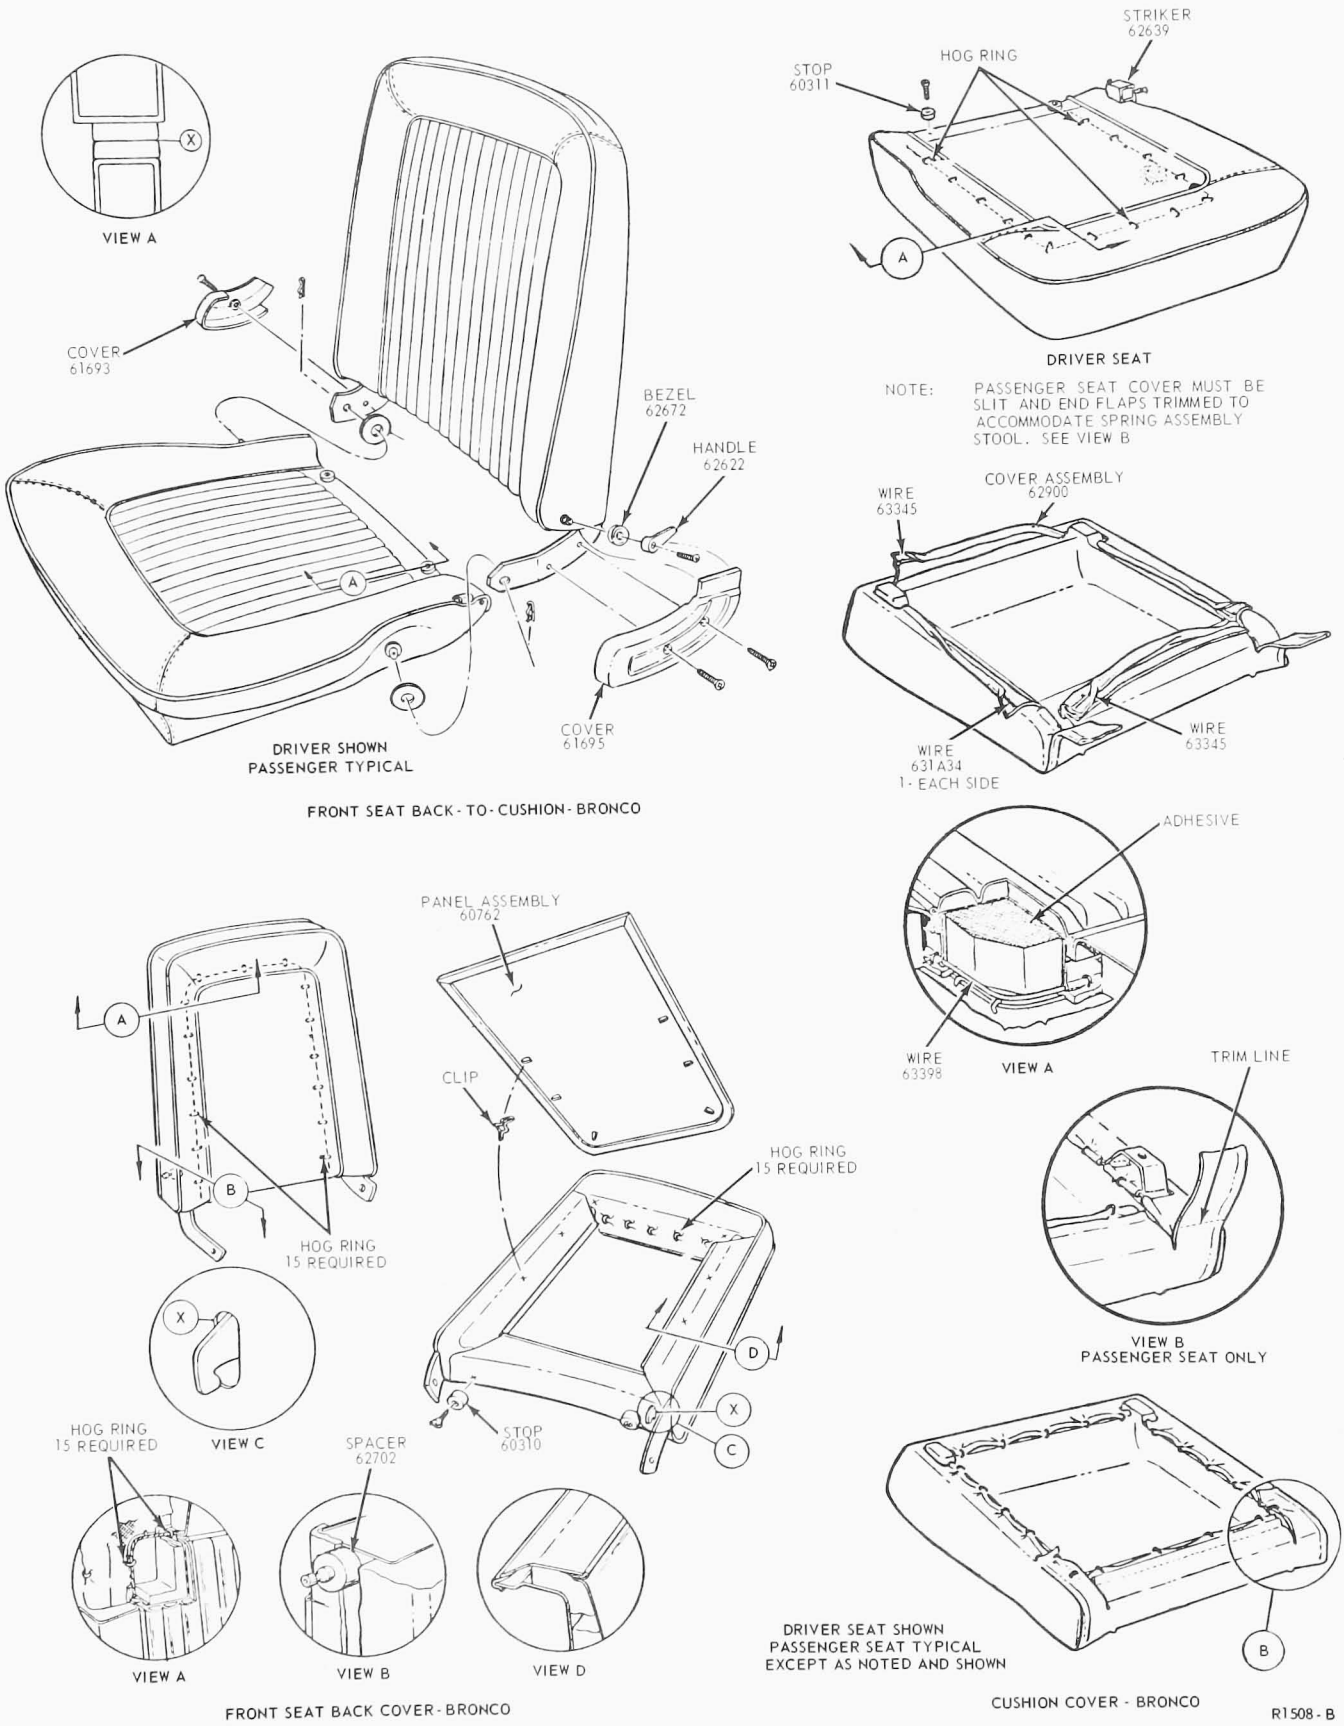

FIG. 1 Front Seat Cushion and Back Cover Installation— Bronco—Bucket Seat

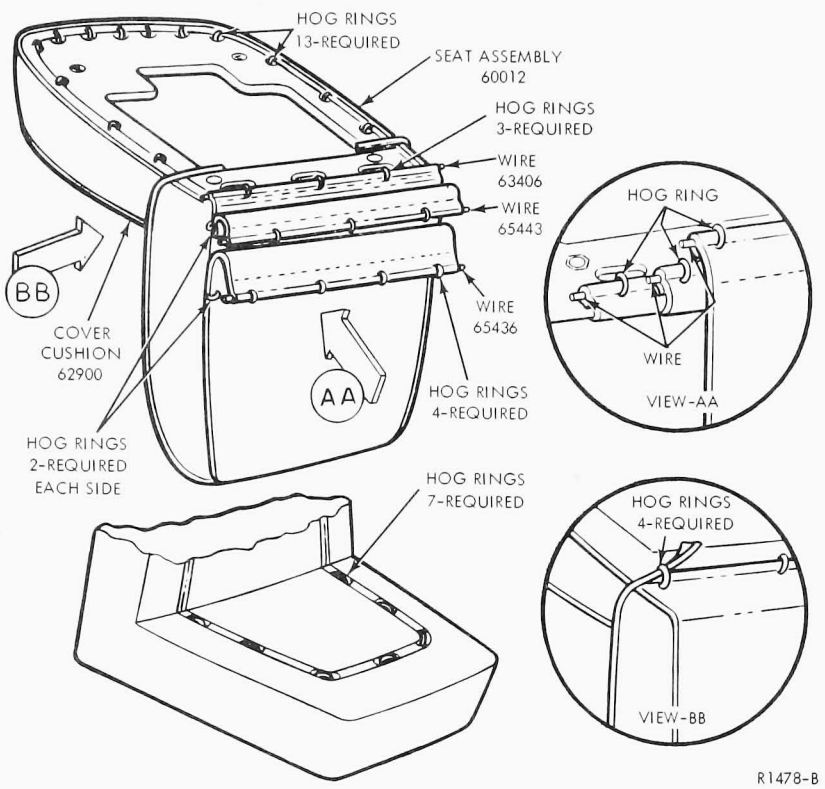

FIG. 2 Front Seat Cover Assemblies—Econoline

2. Remove the lock nut and washer from the seat back stop bolt (See Fig. 2, Part 41-01).
3. Remove the bolt and nut attaching the seat back frame to the side of the seat cushion.
4. Remove the screw and washer retaining the center hinge cover in place and position the cover out of the way.
5. Remove the seat back and remove the stop bolt and nuts from the seat back.
6. Install the stop bolt and nuts on the seat back.
7. Position the seat back to the seat cushion, and install the seat back frame-to-cushion attaching bolt and nut (See Fig. 2, Part 41-01).
8. Position the seat track to the floor pan, install the retaining nuts and washers, and tighten to specification shown in Group 41, Specifications section.
9. Position the seat back stop in the cushion bracket and install the washer and lock nut. Then, adjust the seat back for the desired angle.
10. Locate the center hinge cover in position and install the washer and retaining screw.

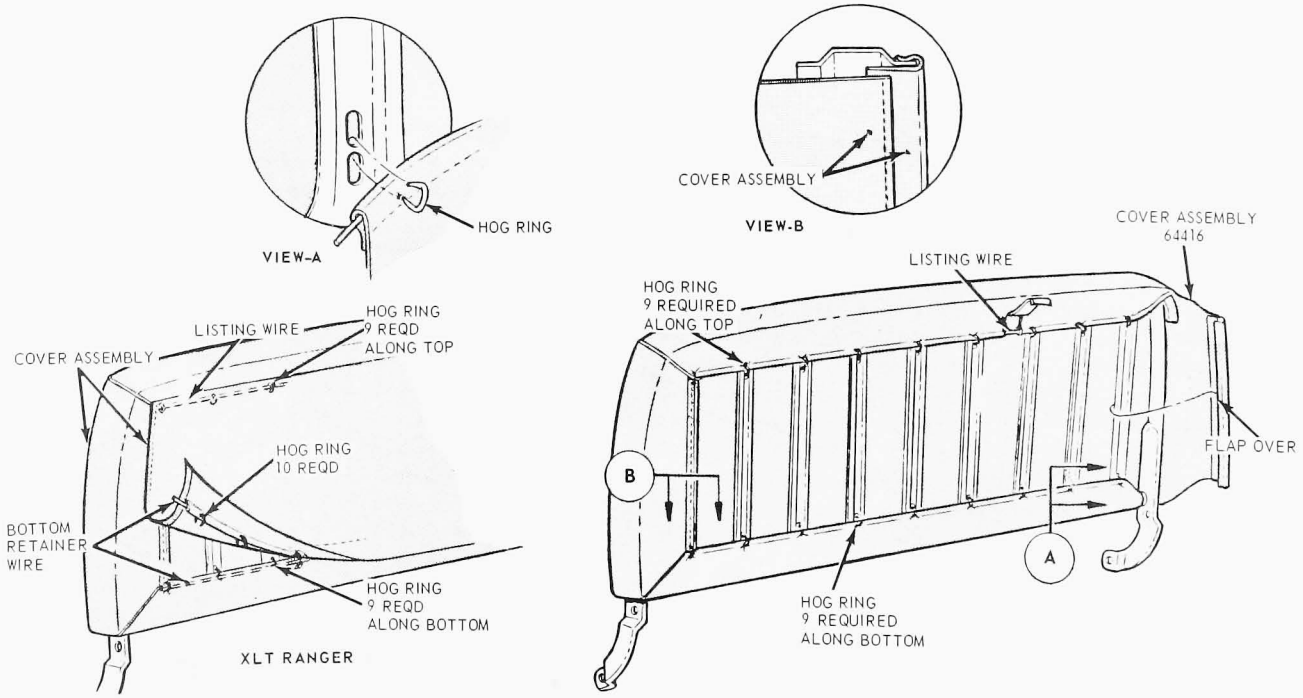

FIG. 3 Seat Back Cover Installation—Typical

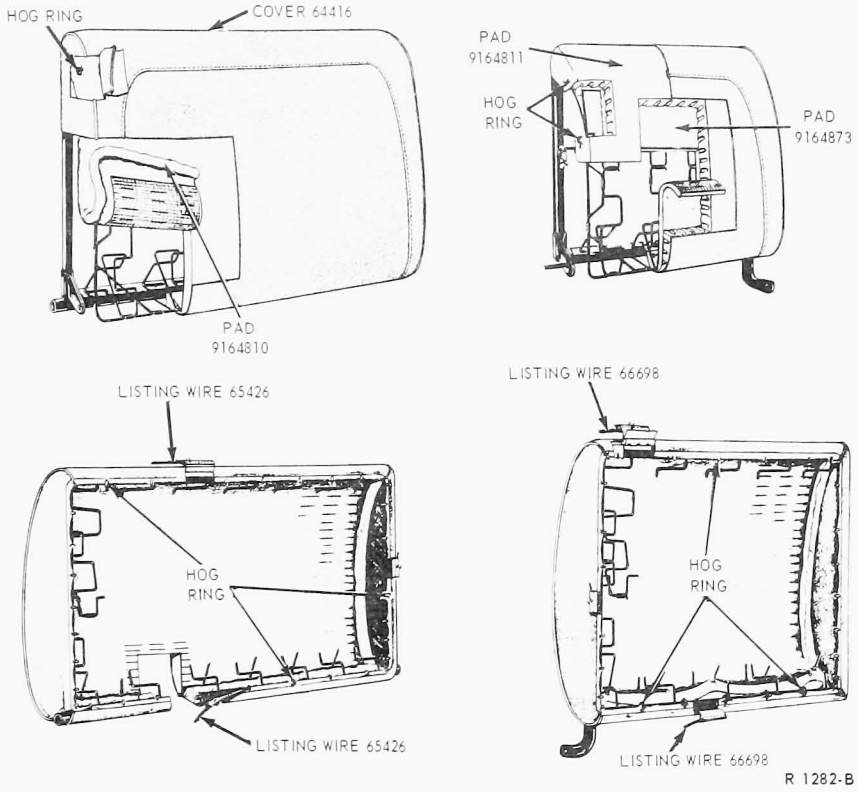

FIG. 4 Seat Back Cover Installation—C-Series

SEAT BACK—RIGHT SIDE

C-SERIES

1. Remove the left seat back from the seat frame as outlined in the foregoing procedure.
2. Remove the right seat back panel attaching screws and remove the panel from the seat back (See Fig. 2, Part 41-01).
3. Remove the pin and washer from the right side pivot. Slide the right seat back toward the left side of the seat and remove it from the seat cushion.
4. Remove the seat back stop scuff plate from the lower edge of the seat back.
5. Install the seat back stop scuff plate on the lower edge of the seat back.
6. Position the right seat back to the seat frame and install the left seat back. Install the washer and pin at the right side pivot.
7. Position the right seat back panel on the seat back and install the attaching screws.
8. Lock the right seat back in place.
9. Install the left seat back as outlined in the foregoing procedure.

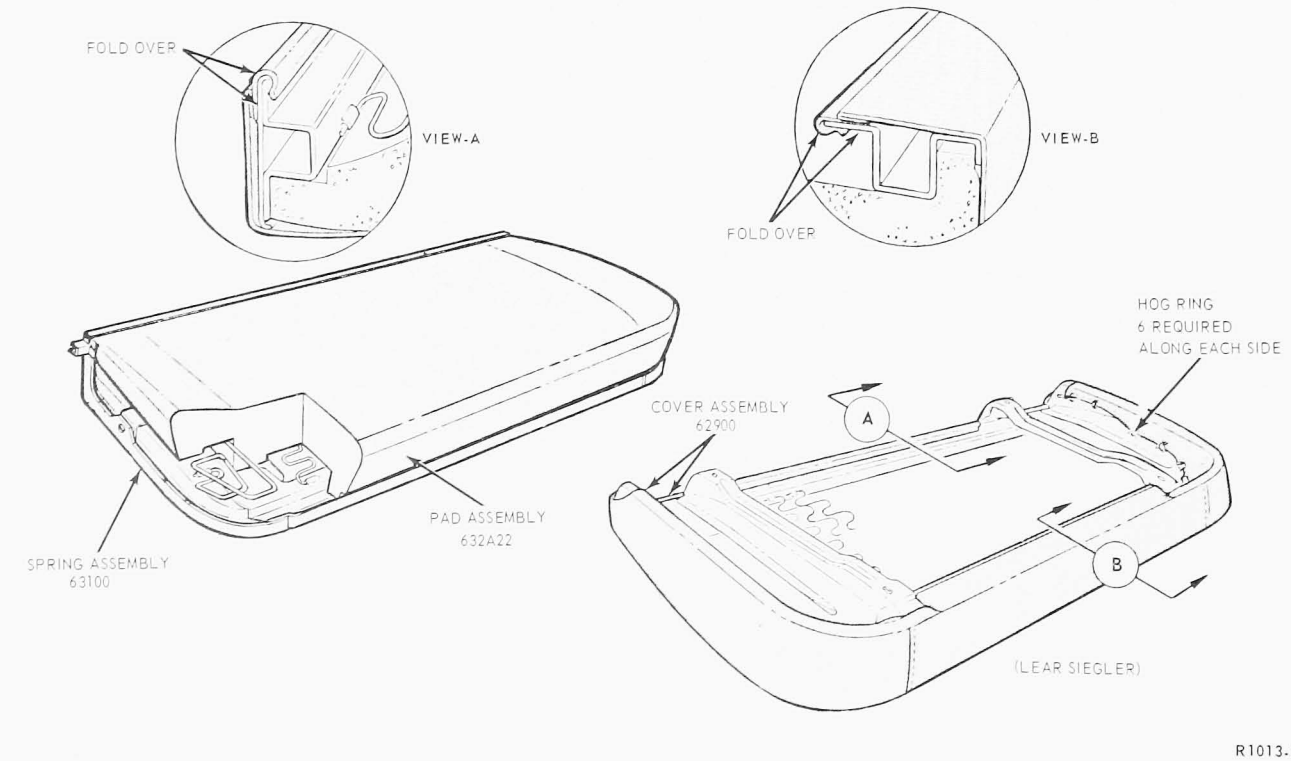

FIG. 5 Seat Cushion Cover Installation—Typical

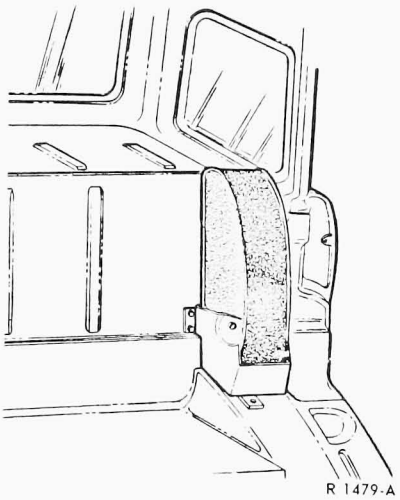

FIG. 6 Arm Rest Installation—C-Series

ARM REST—C-SERIES

To remove the arm rest from the cab, remove the five retaining bolts (Fig. 6).

Position the arm rest assembly to the floor pan and cab back. Install the five retaining bolts.

PART 41-70 Bostrom Viking Seat

COMPONENT INDEX Applies To Models As Indicated	MODEL APPLICATION L-Series	 W-Series
ADJUSTMENTS		
Seat Back	70-01	70-01
Seat Level	70-01	70-01
REMOVAL AND INSTALLATION		
Seat Back	70-02	70-02
Seat Cushion	70-02	70-02
Seat and/or Seat Track	70-02	70-02
Shock Absorber	70-03	70-03
Torsion Bar	70-02	70-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

SEAT BACK

The angle of the seat back can be adjusted to any of three positions. To adjust the seat back angle, lift the seat back up and slide it to the desired position.

SEAT LEVEL

The seat level weight adjustment is controlled by the adjuster lever located at the right rear corner of the seat cushion (Fig. 1). The adjuster lever increases with (clockwise rotation) or decreases with (counterclockwise rotation) the twist applied to the torsion bar to control the up and down travel of the seat and prevent it from reaching the end of its travel.

The seat is properly adjusted for weight when the indicator tip (located on the inside edge of the left seat back support) is flush with the front edge of the support. This adjustment must be made when the seat is occupied.

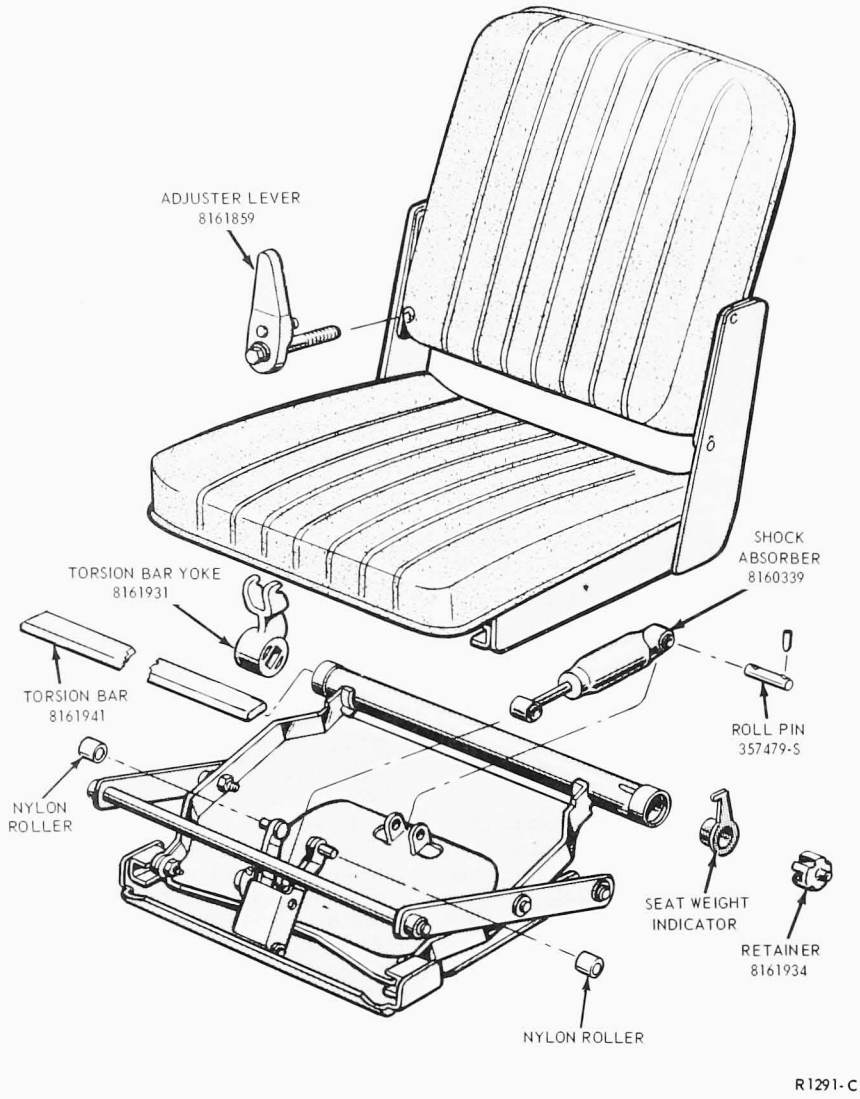

FIG. 1 Bostrom Viking Seat—Disassembled

REMOVAL AND INSTALLATION

SEAT AND/OR SEAT TRACK

1. Remove four nuts and washers attaching the seat track to the floor pan and remove the seat and seat track.
2. Remove 4 nuts and washers attaching the seat tracks to the seat mechanism and remove the tracks from the seat.
3. Position the seat tracks to the seat and install the nuts and washers; then, position the seat and seat track in the vehicle, install the retaining washers and nuts and torque 12-25

SEAT CUSHION

1. Remove the pre-load on the torsion bar by rotating the adjuster lever counterclockwise until the tension is relieved. It is not necessary to remove the adjuster lever from the seat.
2. Remove four nuts and washers retaining the seat cushion to the seat frame.
3. Slide the cushion forward to disengage the bearings from the slides on the bottom of the seat cushion and remove the cushion.
4. Slide the bearings into the slides on the bottom of the cushion and push the cushion rearward into position. Then, install the retaining nuts and washers.

SEAT BACK

Remove the seat back by removing four screws and washers from the rear of the seat back.

TORSION BAR

1. Remove four nuts and washers attaching the seat mechanism to the

seat tracks and remove the seat from the vehicle.
2. Wedge the seat in the up position by placing a wooden block between the lower seat mechanism frame and the rod under the front edge of the seat cushion (Fig. 1).
3. Remove the pre-load on the torsion bar by rotating the adjuster lever counterclockwise and remove it from the seat.
4. Remove four screws and washers and remove the seat back from the seat frame.
5. Remove the four seat cushion retaining nuts and washers; slide the seat cushion forward and remove it from the seat track mechanism.
6. Remove the right side panel from the seat frame by tapping it lightly with a wooden mallet.
7. Remove the torsion bar.
8. Position the torsion bar inside the seat mechanism tube and engage the bar with the slot in the retainer (Fig. 1).
9. Position the right seat frame side and yoke to the seat frame. Engage the yoke with the torsion bar and assemble the seat frame so that the cushion attaching studs are in line with the seat frame holes.
10. Install the seat cushion and seat back on the frame.
11. Install the adjuster lever and engage the adjuster pin in the hooks on the torsion bar yoke (Fig. 2).
12. Apply pre-load to the torsion bar by rotating the adjuster lever clockwise and remove the block from under the front of the seat. Then install the seat in the vehicle.

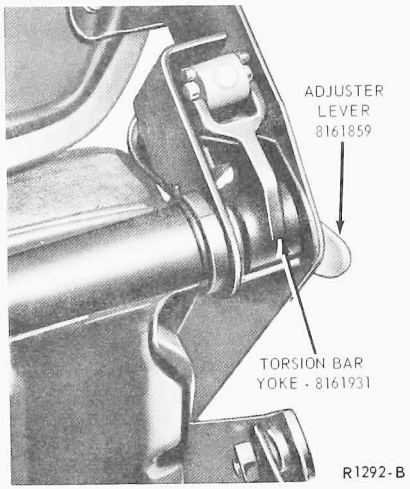

FIG. 2 Bostrom Seat Adjuster Lever—Installed

SHOCK ABSORBER

1. Wedge the seat in the up position by placing a wooden block between the lower seat mechanism frame and the rod under the front edge of the seat cushion (Fig. 1).
2. Remove the pre-load on the torsion bar by rotating the adjuster lever counterclockwise until the tension is relieved. It is not necessary to remove the adjuster lever from the seat.
3. Remove the seat cushion retaining nuts and washers; slide the seat cushion forward and remove it from the seat track mechanism.
4. Wire the side panel assemblies across the front of the seat to retain their position.
5. Remove the snap rings from the shock absorber front pivot shaft. With a drift, remove the pivot shaft, driving from the side opposite the serrations on the shaft.
6. With a small diameter punch or drift, remove the two roll pins from the shock absorber rear pivot shaft.
7. Remove the pivot shaft with a punch or drift and remove the shock absorber.
8. Position the shock absorber base to the rear attachment and install the pivot shaft. Then, install the roll pins in the shaft.
9. Position the shock absorber shaft to the front attachment. Install the pivot shaft with the serrations on the right side of the seat. Then, install the snap rings on the pivot shaft.
10. Remove the wood brace from the seat frame and install the seat cushion on the seat mechanism. Be sure that the bearings engage with the bottom of the seat cushion.
11. Remove the wooden block from under the front edge of the seat and adjust the torsion bar pre-load by rotating the adjuster lever clockwise.

PART 41-71 Bostrom Westcoaster Seat

COMPONENT INDEX Applies To Models As Indicated	MODEL APPLICATION L-Series	 W-Series
ADJUSTMENTS	71-01	71-01
REMOVAL AND INSTALLATION	71-02	71-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

The seat weight adjustment handle is located at the front of the pedestal support beneath the seat cushion. The handle adjusts the softness of the ride and is adjusted according to the driver's weight.

The seat back angle can be set at one of three different positions for maximum comfort. The seat back angle control is located at the left of the seat back at the lower outside edge.

Seat height may be adjusted by turning the oval-shaped control at the left side of the seat support pedestal.

Horizontal or forward and rearward seat adjustment is controlled by the handle located at the lower left side of the seat cushion (Fig. 1).

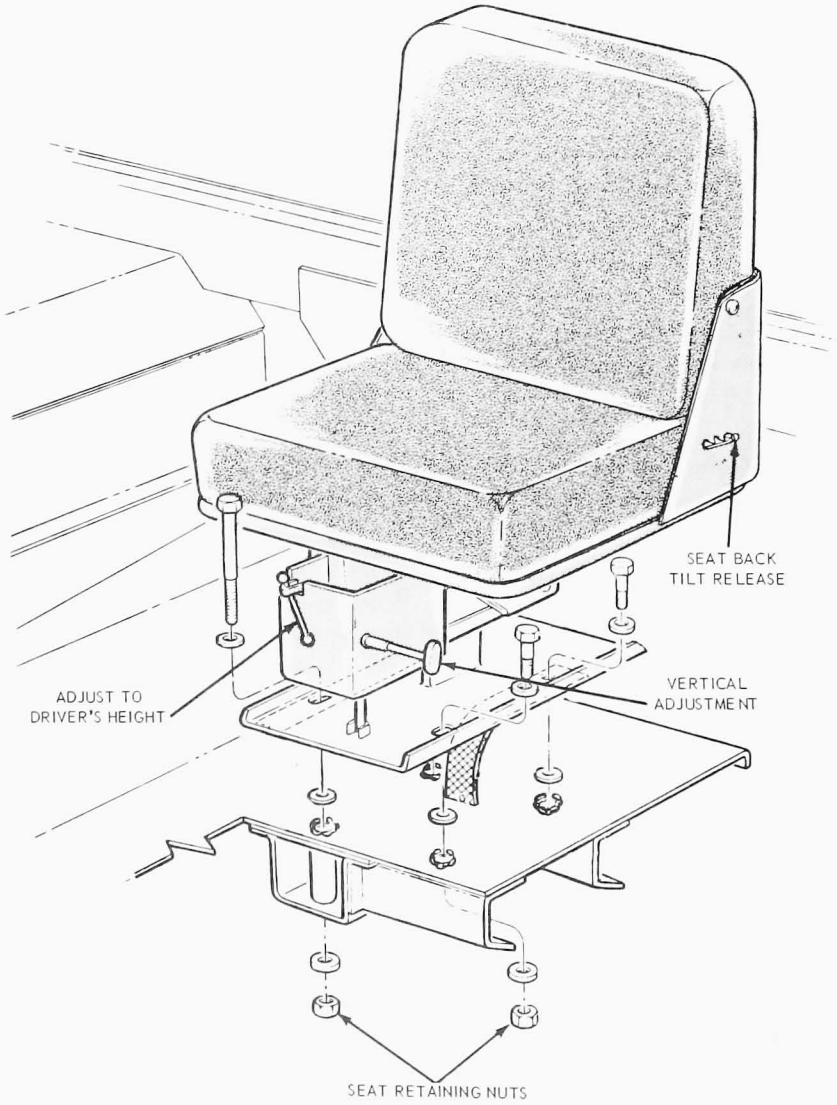

FIG. 1 Bostrom Westcoaster—L-W-Series

REMOVAL AND INSTALLATION

SEAT ASSEMBLY

Remove the four nut and washers retaining the seat assembly from the floor pan (Fig. 1). Discard all four washers between the seat pedestal and the floor pan, (if so equipped). Remove the seat assembly from the vehicle.

Position the seat in the vehicle install the four retaining nuts and washers and torque 12-20 Ft-LB.

TORSION SPRING

Removal

1. Remove the seat assembly from the cab.
2. Before starting disassembly, turn the height adjustment lever clockwise until the seat is at its highest position.
3. Remove the shock absorber.
4. Remove the roll pins from the rear hinge pins; drive the hinge pins from the same end from which the roll pins were removed (the opposite end of the hinge pin is serrated). The upper seat structure is now free and can be removed.
5. Drive out the roll pin in the end of the adjuster stud. Unscrew the adjuster stud from the adjuster pin and remove the entire adjusting screw assembly.
6. Remove the front upper and lower hinge pins. The spring support bracket can now be swung down out of the way, freeing the upper and lower arm assemblies.
7. Remove the lower arm assembly and torsion spring. Take the adjuster pin off the torsion spring.
8. Replace the torsion spring. Check all flanged bearings and replace them if necessary.

Installation

1. Replace the adjuster pin in the torsion spring. Seat the bushing in the spring and install the lower arm assembly. Be sure that the bearings are in place. (The adjuster pin flange on the spring must be to the rear).
2. Raise the spring support bracket and slide the lower arm assembly and lower pivot arm (with the bearing in place) into it. Be sure that the adjuster pin is on top of the lower pivot arm. Secure these units by installing the support pin and the roll pin.
3. Place a 2 x 4 inch block of wood approximately 5 inches long under the support rod of the lower arm assembly to hold it in a raised position. This raises the adjuster pin to permit reassembling the stud.
4. Using a screwdriver or flat bar, raise the spring so that the stud can be screwed back into the adjuster pin and secure it with the roll pin.
5. Replace the upper arm and bearings in the seat adjuster and bracket assembly with the upper pin. Replace the roll pin.
6. Assemble the upper seat structure to the lower arm assembly (with bearings in place) by replacing the lower pin. Insert the roll pin.
7. Align the holes in the upper arm, the pivot arm and the spring support bracket and replace the support pin and the roll pin.
8. Connect the shock absorber and check the operation of the seat adjusting mechanisms.

PART 41-73 Unison No. 675 Roadrunner Seat

COMPONENT INDEX Applies To Models As Indicated	MODEL APPLICATION L-Series	 W-Series
ADJUSTMENTS	73-01	73-01
REMOVAL AND INSTALLATION	73-02	73-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

Refer to Figure 1 for call-outs refering to back, seat height and weight adjustments. The horizontal, or forward and rearward seat track control lever is also shown.

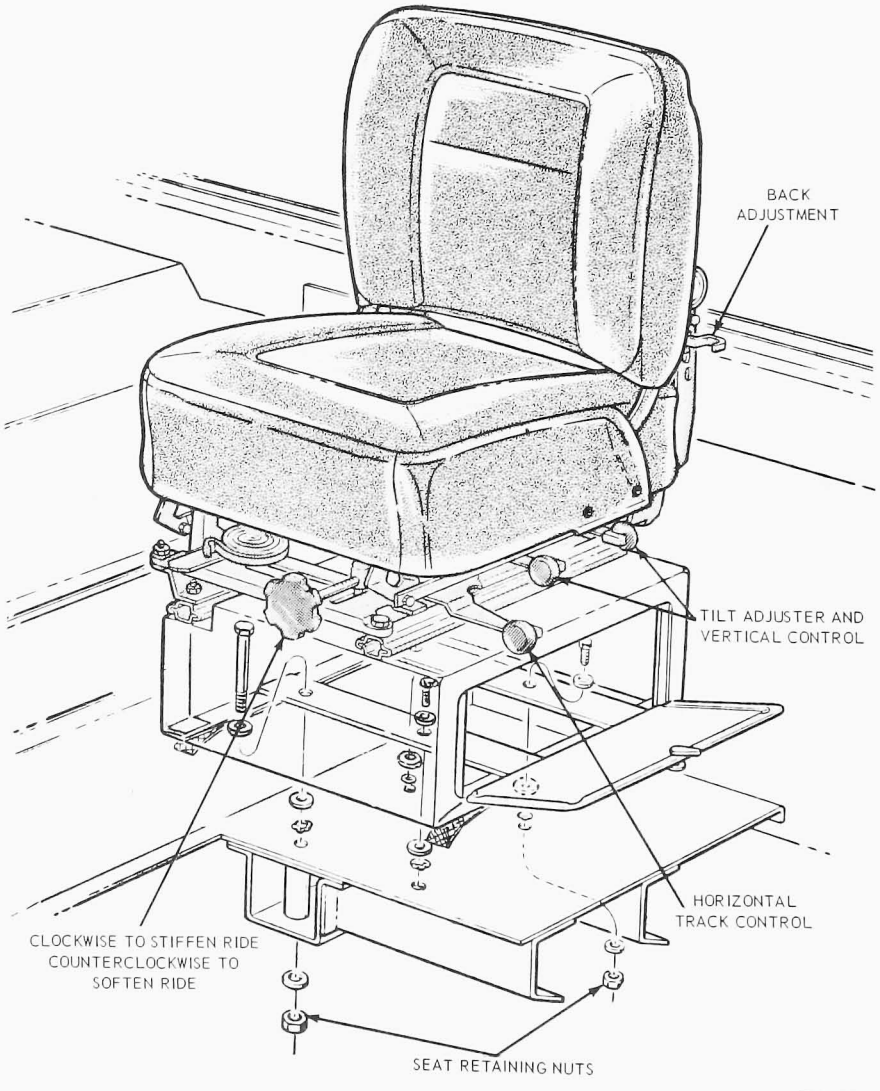

FIG. 1 Installation Unison No. 675 Roadrunner Seat— Typical Unison No. 675

REMOVAL AND INSTALLATION

SEAT AND/OR SEAT TRACK

Remove the four nuts and washers attaching the seat pedestal to the seat track (Fig. 1). Remove the seat assembly from the vehicle. Remove the four nuts attaching the seat track to the pedestal and remove the seat tracks.

Position the seat tracks to the seat assembly and fasten the retaining nuts (Fig. 1). Position the seat assembly to the pedestal and install the retaining nuts and torque 12-20 ft-lb.

PART 41-74 Cush-N-Aire Seat

COMPONENT INDEX Applies To Models As Indicated	MODEL APPLICATION W-Series
DESCRIPTION AND OPERATION	74-01
ADJUSTMENTS	74-01
REMOVAL AND INSTALLATION	74-02

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

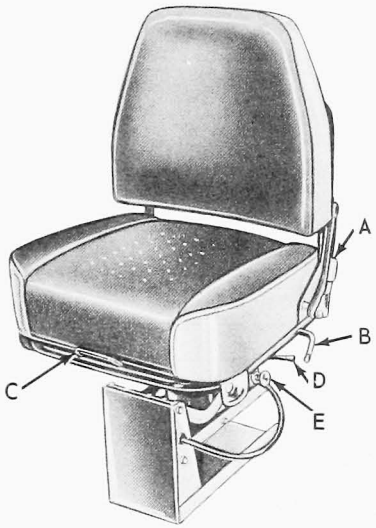
DESCRIPTION AND OPERATION

This seat provides five adjustments to accommodate the size, weight and proportions of the driver. The adjustments described here are illustrated in Figure 1.

1. **FRONT SEAT BACK ANGLE—Four tilting angle positions (3 inches of adjustment)—** Push on the seat back adjusting handle, lean back to the desired position and release the handle.
2. **CUSHION REAR TILT—Four height positions (2 inches of adjustment)—** Rotate the cushion rear adjusting handle clockwise to raise, or counterclockwise to lower the rear part of the cushion.
3. **CUSHION POINT TILT—Three height positions (1 inch of adjustment for upward tilt, 2 inches of adjustment for downward tilt)—** Lift up on the cushion lift handle and pull up and forward to the desired position.
4. **SEAT TRACK—Nine forward and backward positions (4 inches of adjustment)—** Move the seat track adjusting lever toward the front of the seat, slide the seat forward or backward to the desired position, and release the lever.
5. **SEAT HEIGHT—(Six inches of adjustment)—** To raise the seat (inflate), push in the air control valve button. To lower the seat (deflate), pull out the air control valve button.

ADJUSTMENTS

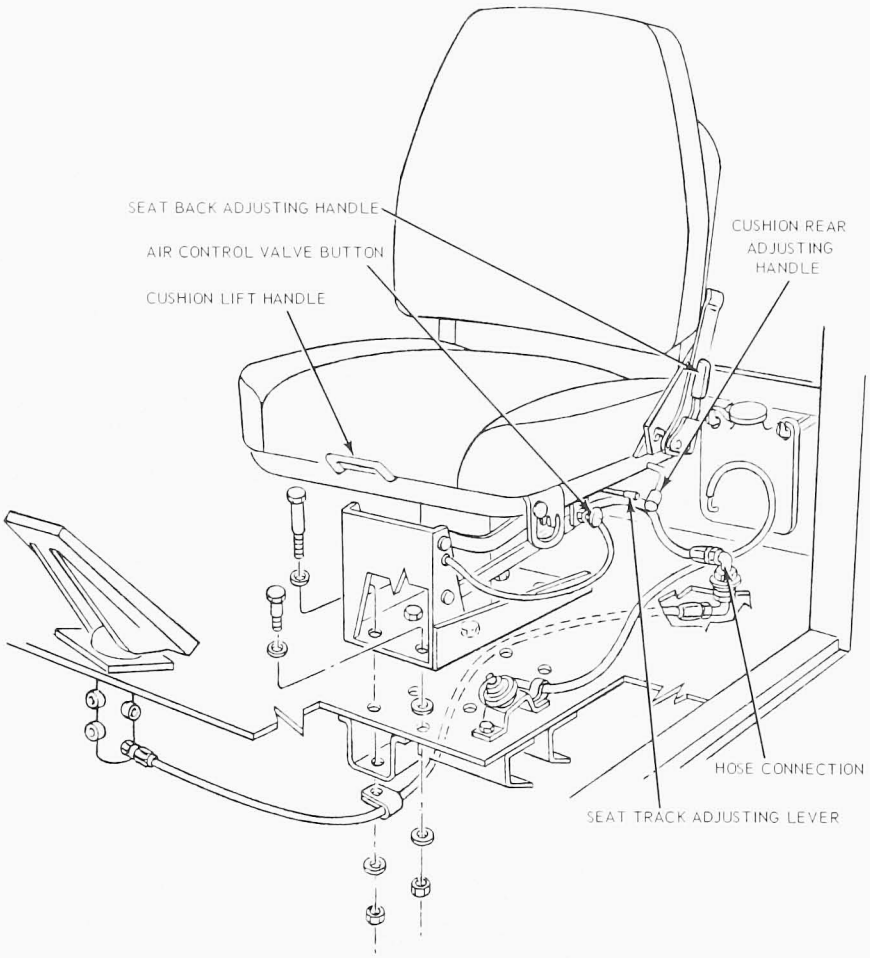
Refer to figs. 1 and 2 for seat back angle and height and weight adjustments.



A FOUR BACK ANGLE TILTING POSITIONS–PUSH ON HANDLE, LEAN BACK.
B FOUR AFT CUSHION HEIGHT POSITIONS–ROTATE HANDLE CLOCKWISE.
C THREE FRONT CUSHION HEIGHT POSITIONS AND CUSHION DEPTH ADJUSTMENTS–LIFT ON HANDLE, PULL UP AND FORWARD.
D NINE FORE AND AFT POSITIONS–PULL LEVER TOWARD FRONT AND SLIDE.
E PUSH AIR BUTTON TO INFLATE–PULL AIR BUTTON TO DEFLATE FOR UP AND DOWN MOVEMENT.

R1510-A

FIG. 1 Cush-N-Aire Seat—Adjustments



R1487-A

FIG. 2 Cush-N-Aire Seat—Exploded

REMOVAL AND INSTALLATION

To remove the seat assembly, remove the four seat track to seat track support retaining nuts. Disconnect the air hose and remove the seat from the support. If the seat support assembly is to be removed, remove the retaining nuts and washers from underneath the floor pan.

When installing, tighten the seat support assembly-to-floor pan nuts 12-20 ft-lbs and the seat track-to-seat track support nuts to 7-12 ft-lbs.

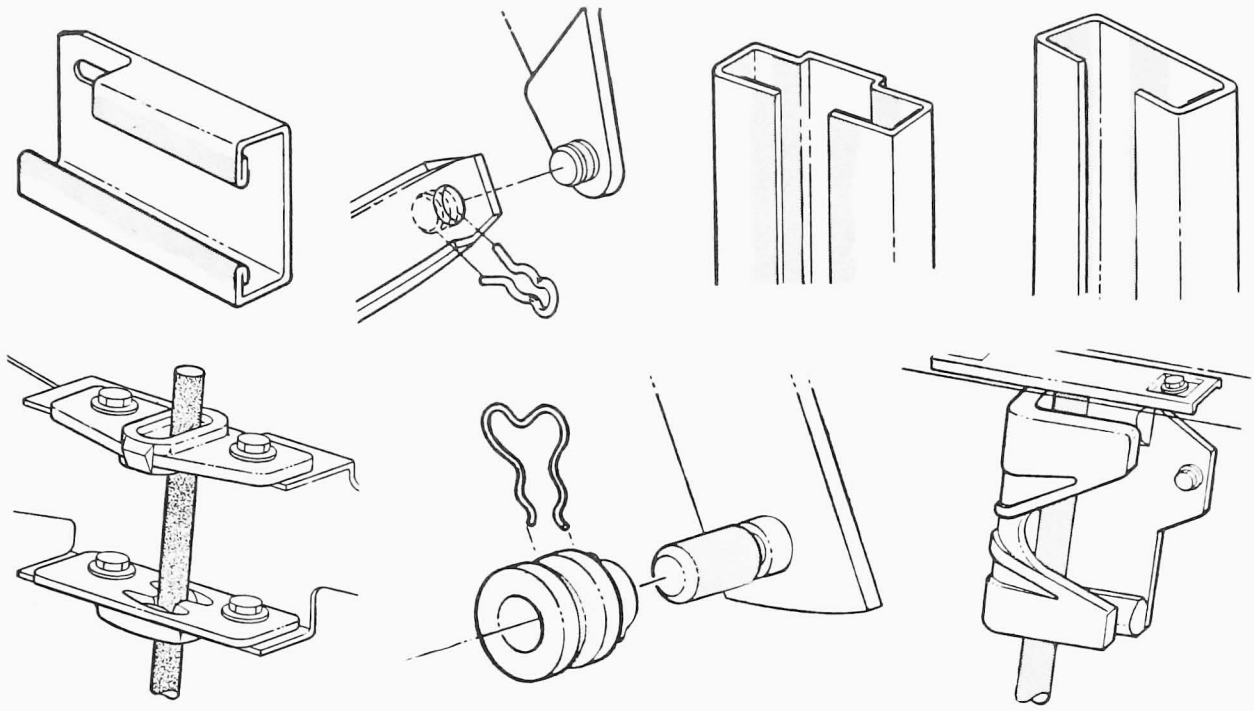
PART 42-01 Window Glass and Mechanisms General Service

GENERAL INFORMATION

WINDOW MECHANISM LUBRICATION

The door window mechanism should be properly lubricated to provide ease of operation. The window glass mechanism should be lubricated whenever the glass channel or window regulator is removed or excessive effort is required to operate the windows. To lubricate a door window mechanism, apply an even coating of Polyethylene grease (C4AZ-19584-A) to the window regulator rollers, shafts and the entire length of the roller guides as illustrated by the shaded areas in Fig. 1.



APPLY AN EVEN COATING OF POLYETHYLENE GREASE (C4AZ-19584-A) TO ALL WINDOW REGULATOR ROLLERS, SHAFTS AND THE ENTIRE LENGTH OF ROLLER GUIDES AS ILLUSTRATED BY THE SHADED AREAS.

ADJUSTMENTS

WINDOW MECHANISM ADJUSTMENT

ECONOLINE

1. Remove the trim panel from the door, if so equipped.
2. Remove the access cover from the door.
3. Loosen the front run retainer and division bar lower attaching screw and the rear run retainer lower attaching screw (Items C and D, Fig. 1).
4. Lower the window glass until the top edge of the glass is approximately four inches above the belt line (Fig. 1).
5. Tighten the screws (Items C and D) and check the operation of the window mechanism.
6. Install the access cover and, if so equipped, the trim panel on the door.

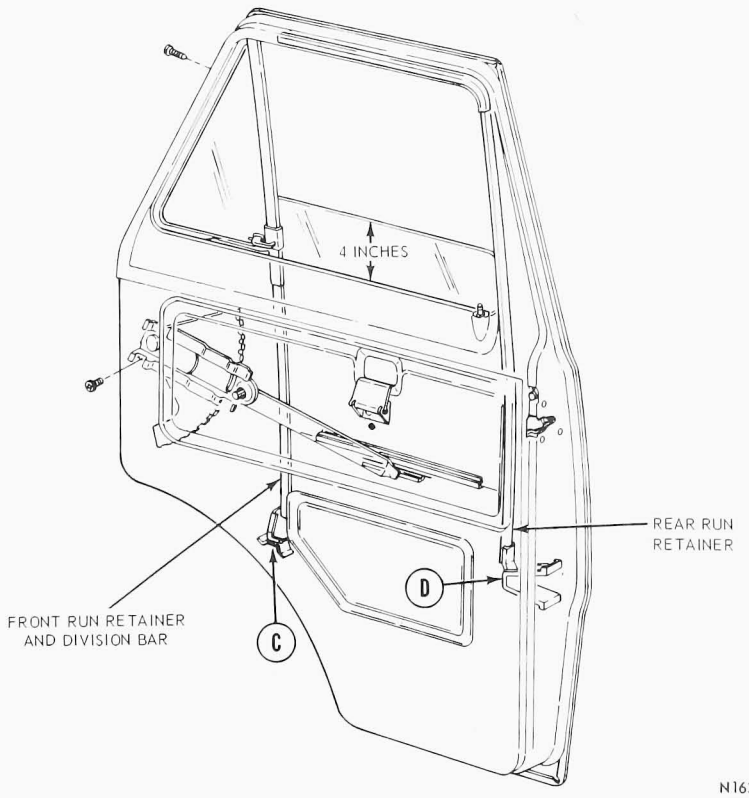

FIG. 1 Front Door Window Glass Adjustment—Econoline

BRONCO

1. Lower the window glass until the top edge of the glass is flush with the bottom of the window opening. Then, position the lower stop bracket bumper against the glass channel (Fig. 2) and tighten the attaching screw.
2. Loosen the rear run and bracket lower attaching screw.
3. Raise the window until the top edge of the glass is approximately four inches above the bottom of the window opening. Allow the rear run and bracket to move as necessary for proper alignment with the window glass. Then, tighten the rear run and bracket lower attaching screw.
4. Lower the glass and loosen the division bar lower run and bracket attaching screw (Fig. 2). Position the division bar lower run against the glass and tighten the attaching screw.

DOOR WINDOW ADJUSTMENT

F-SERIES

The door trim panel and watershield must be removed to adjust the window mechanism.

1. Loosen the nut and washer at the lower end of the vent window division bar (Fig. 3) so that the lower end of the division bar is free to move inboard or outboard.
2. Loosen the rear run two lower attaching screws (Fig. 1).
3. Lower the glass 1/3 of the way

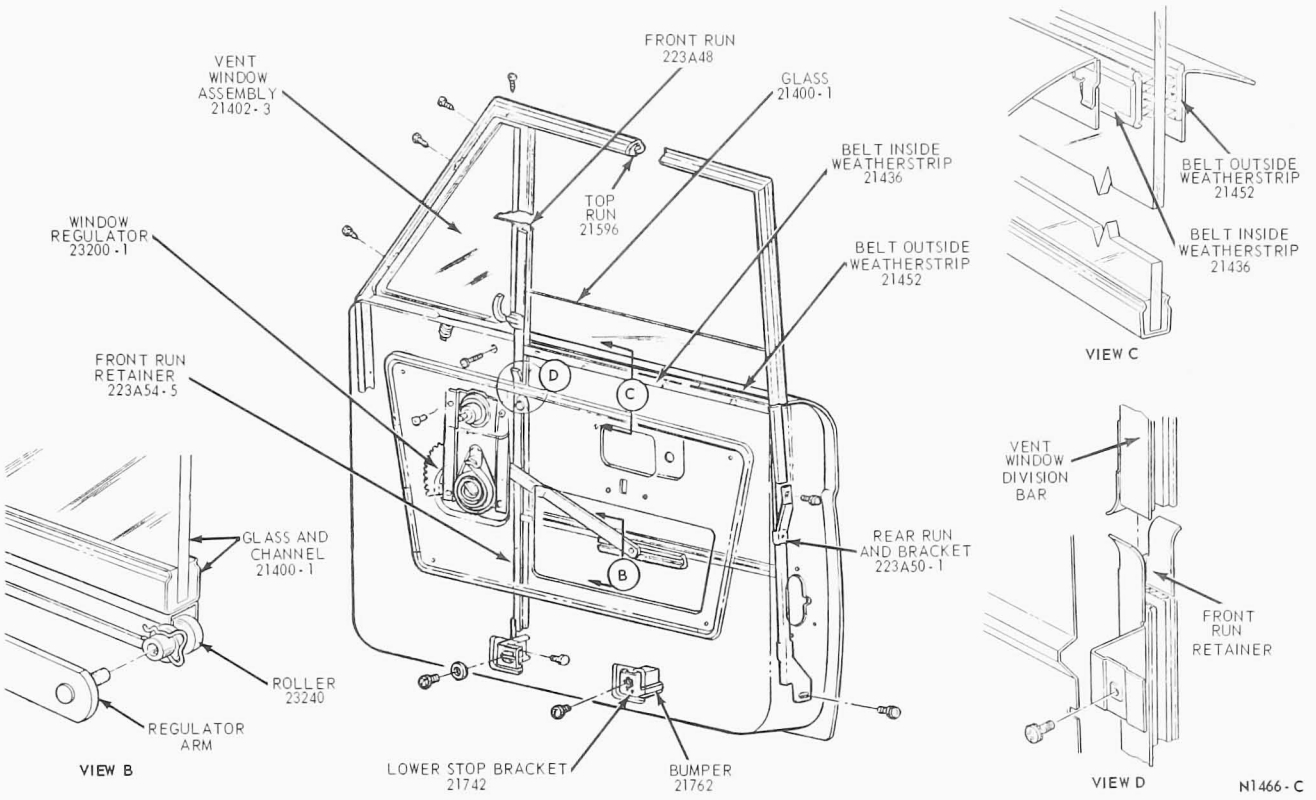

FIG. 2 Door Window Mechanism—Bronco

down. Adjust the stud at the lower end of the division bar in or out until the washer on the stud just comes against the door inner panel. Then, tighten the nut and washer assembly (Fig. 3).

4. Tighten the rear run lower two attaching screws.
5. Lower the glass and check the height of the top edge of the glass. It should be about flush with the belt line. If adjustment is necessary, loosen the regulator attaching screws and rotate the regulator down and forward to lower the glass, or up and rearward to raise the glass. Then, tighten the regulator attaching screws when the correct height is obtained.

REMOVAL AND INSTALLATION

ECONOLINE

Removal

FRONT DOOR GLASS

1. Remove the access cover from the door inner panel.
2. Remove three screws attaching the vent window assembly to the upper leading edge of the door (Fig. 4).
3. Remove one screw attaching the vent window assembly to the door at the belt line (Fig. 4).
4. Remove one screw attaching the front run retainer and division bar bracket to the door.
5. Slide the front run from the front run retainer and division bar.
6. Disconnect the regulator arm roller from the regulator arm by removing the roller retaining clip (Fig. 4) and pulling the arm from the roller.
7. Unsnap and remove the belt line weatherstrips from the door.
8. Pull the rear run down and out of the run slot in the door along the top of the glass opening.
9. Tilt the vent window and division bar assembly rearward and separate the vent window from the front run retainer and division bar. Then, remove the vent window and the front run retainer and division bar from the door.
10. Remove the glass and channel assembly from the door.
11. Remove the glass channel from the glass with the tool shown in Fig. 5.

Installation

1. Install the glass channel on the glass with the tool shown in Fig. 5.
2. Lubricate the window mechanism as shown in Part 42-02.
3. Place the glass and channel assembly in the door.
4. Position the vent window and the front run retainer and division bar in

the door. Then, insert the front run retainer and division bar in the rear edge of the vent window.
5. Position the glass and channel assembly in the front run retainer and division bar and the rear run. Then, place the vent window assembly into position in the door, and install the three screws attaching the vent frame to the upper leading edge of the door.
6. Install the belt line weatherstrips.
7. Insert the rear run into the slot along the top edge of the window opening.
8. Insert the retaining clip on the regulator arm roller and insert the roller in the glass channel.
9. Insert the window regulator arm pin in the roller and press firmly to lock the roller on the regulator arm.
10. Insert the front run in the front run retainer and division bar.
11. Install the screw attaching the front run retainer and division bar bracket to the door.
12. Install the vent window attaching screw at the belt line.
13. Adjust the window glass run as outlined in Adjustments.
14. Install the access cover on the door.

BRONCO

Removal
1. Remove the trim or access panel from the door.
2. Remove the glass lower stop from the door (Fig. 2).
3. Lower the glass and remove the belt inner weatherstrip.
4. Remove the vent window attaching screws (Fig. 2).
5. Pull the door glass top run down and away from the vent window assembly.
6. Remove the vent window assembly from the door (Fig. 2).
7. Disconnect the regulator arm from the roller and remove the roller from the glass channel.
8. Lift the glass and channel assembly from the door.

Installation
1. Lubricate the glass and channel assembly (Part 42-02).
2. Position the glass and channel assembly into the door and insert the roller into the glass channel.
3. Position the regulator arm to the roller and press the arm into the roller.
4. Position the vent window assembly in the door and install the attaching screws.
5. Insert the door glass top run into the top of the door.
6. Install the belt inner weatherstrip.
7. Install and adjust the glass lower stop.

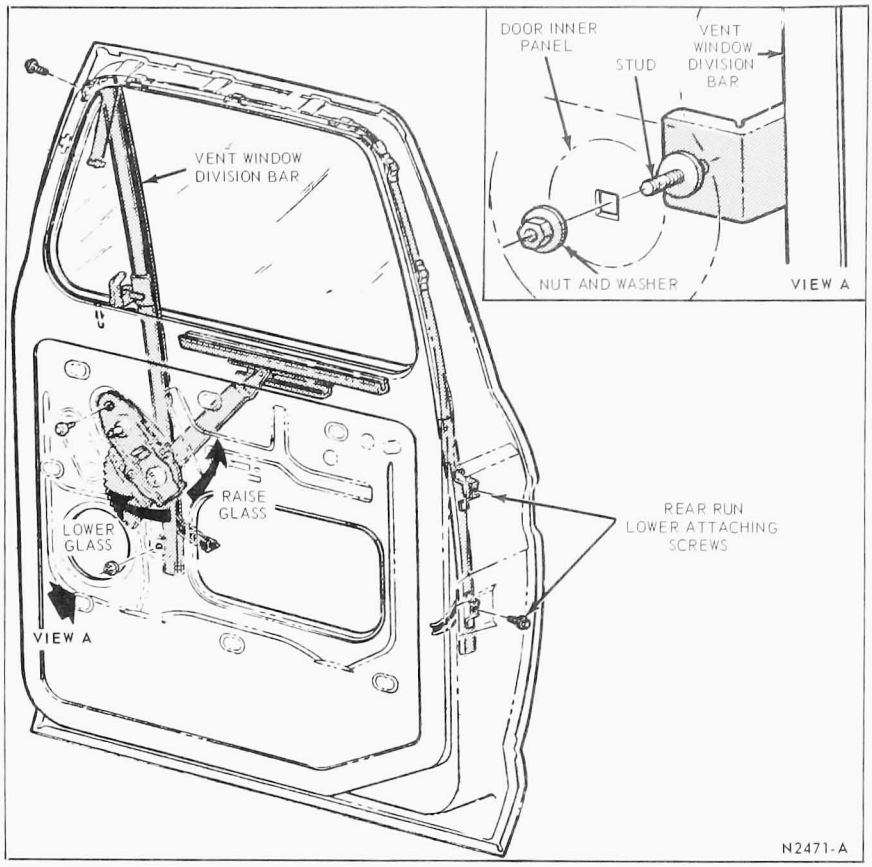

FIG. 3 Window Mechanism Adjustment—F-Series Truck

8. Install the trim panel on the door.

F-100 THROUGH F-750

Removal
1. Remove the door trim panel.
2. Remove the nut from the front run retainer stud (Fig. 6).
3. Remove three vent window assembly attaching screws from the front edge of the door (Fig. 6).
4. Lower the door glass and pull the glass run out of the upper run retainer near the vent window division bar only enough to allow removal of the vent window assembly.
5. Tilt the vent window and division bar assembly toward the rear of the door and remove the vent window from the door.
6. Rotate the front edge of the glass downward and lift the glass from the door.
7. Remove the glass from the glass channel with the tool show in Fig. 5.

Installation
1. Install the glass in the glass channel with the tool shown in Fig. 5.
2. Position the glass and channel assembly into the door, inserting the regulator arm roller into the slot of the glass channel (View B, Fig. 6).
3. Position the vent window and division bar into the door and insert the front edge of the glass into the division bar (front) run.
4. Install the three vent window attaching screws at the forward edge of the door (Fig. 6).
5. Insert the glass run into the upper run retainer near the division bar.
6. Install the nut on the front run retainer stud and adjust as outlined in the Adjustment Section.
7. Check the operation of the window and install the door trim panel.

L-SERIES

Removal
1. Remove the access panel from the door.
2. Remove the vent window division bar retaining screw at the belt line. Also, remove the four screws retaining the vent window assembly to the door frame. Remove the bolt retaining the run to the run retainer bracket.
3. Remove the vent window assembly from the door.
4. Lower the glass to the full down position and disconnect the regulator arms from the channel brackets (Fig. 7).

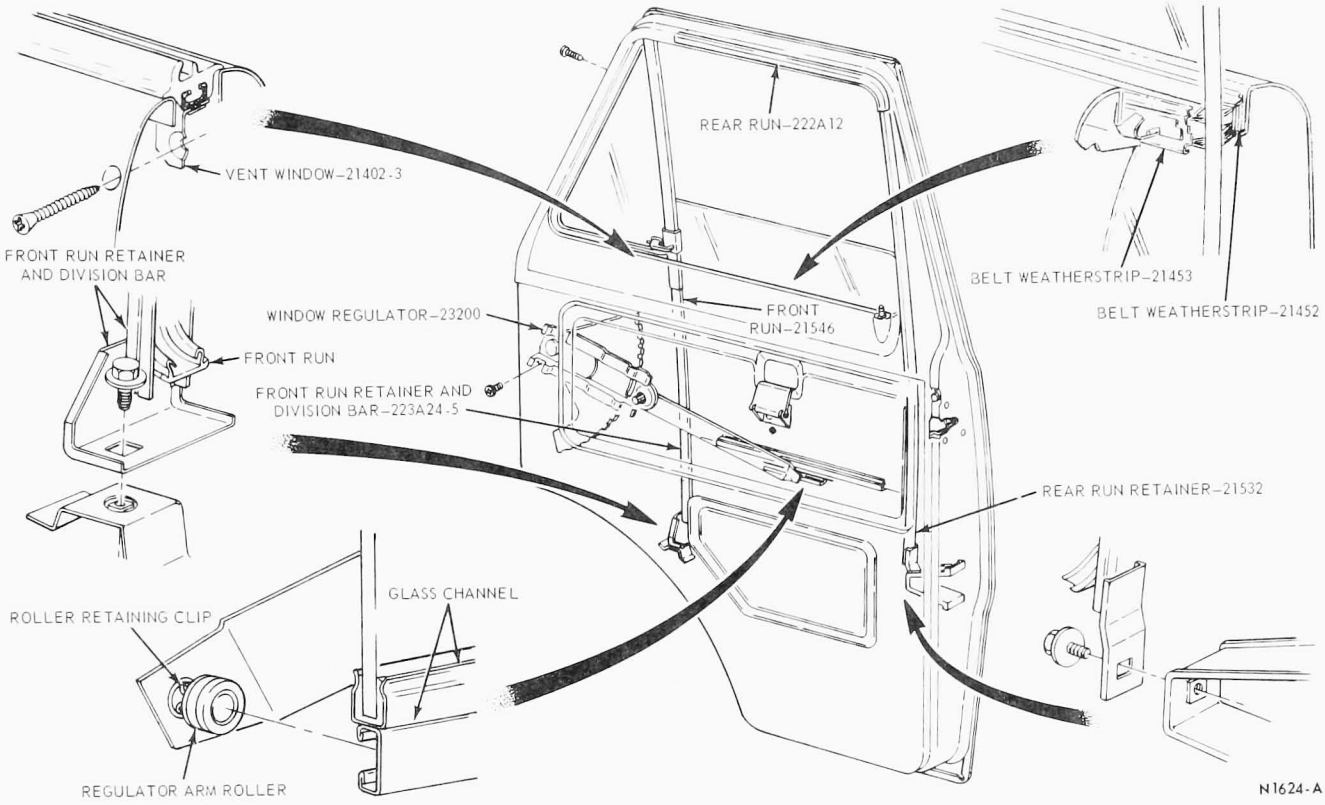

FIG. 4 Front Door Window Mechanism—Econoline

5. Move the regulator arms 3/4 of the way to the up position. Rotate the window glass 90 degrees and remove it through the access opening.

Installation

1. Insert the door glass into the access opening.
2. Lower the regulator arms and connect the regulator arms to the channel brackets on the glass.
3. Install the vent window assembly in the door and install the retaining screws.
4. Loosely install the run retainer in the retainer bracket and cycle the window up and down to be sure it is free from bind. Tighten the run retaining bolt.
5. Install the access panel in the door.

C-SERIES

1. Remove the door access hole cover plate.
2. Loosen the glass rear run upper and lower retaining screws.
3. Remove the division bar upper and center retaining screws and lower retaining bolts (Fig. 8).
4. Lower the door glass and disconnect the regulator arm from the glass channel roller by pulling the retaining clip (Fig. 9).
5. Tilt the top of the division bar toward the rear of the door, and remove the glass through the access hole.
6. Remove the channel from the glass with a glass channel replacer tool (Fig. 5).
7. Install the glass channel on the glass, using new glass tape. Trim the excess tape.
8. If necessary, assemble and install the roller assembly in the glass channel (Fig. 9).
9. Position the glass in the door, and snap the regulator arm pin into the roller assembly.
10. Loosely install the division bar upper and center retaining screws, and lower retaining bolts. Adjust the division bar for proper window operation and tighten the screws and bolts.
11. Adjust the rear run and tighten the screws.
12. Run a bead of sealer around the access hole cover plate, and install the cover plate.

W-SERIES

Removal

1. Remove the check strap and the lower inner panel from the door.
2. Remove the door inside handle by pressing the escutcheon against the door and removing the retaining pin from the handle and shaft (Fig. 10).
3. Remove the upper inner panel attaching screws. Then, pull the inner panel away from the door frame and remove the four door latch remote control attaching screws and nuts.
4. Lower the window and remove the clips retaining the roller assemblies (Fig. 11) to the window regulator arms and pull the arms from the glass channel and rollers. Then, remove the upper inner panel and window regulator from the door.
5. Remove the screws attaching the door latch to the door panel and remove the latch and remote control from the door.

GLASS AND CHANNEL REMOVAL TOOL (NO. 2900) AVAILABLE FROM SOMMER AND MALA GLASS MACHINE COMPANY, 5501 W. OGDEN AVENUE, CHICAGO 50, ILLINOIS

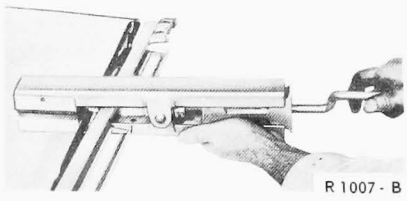

FIG. 5 Glass Channel Replacement

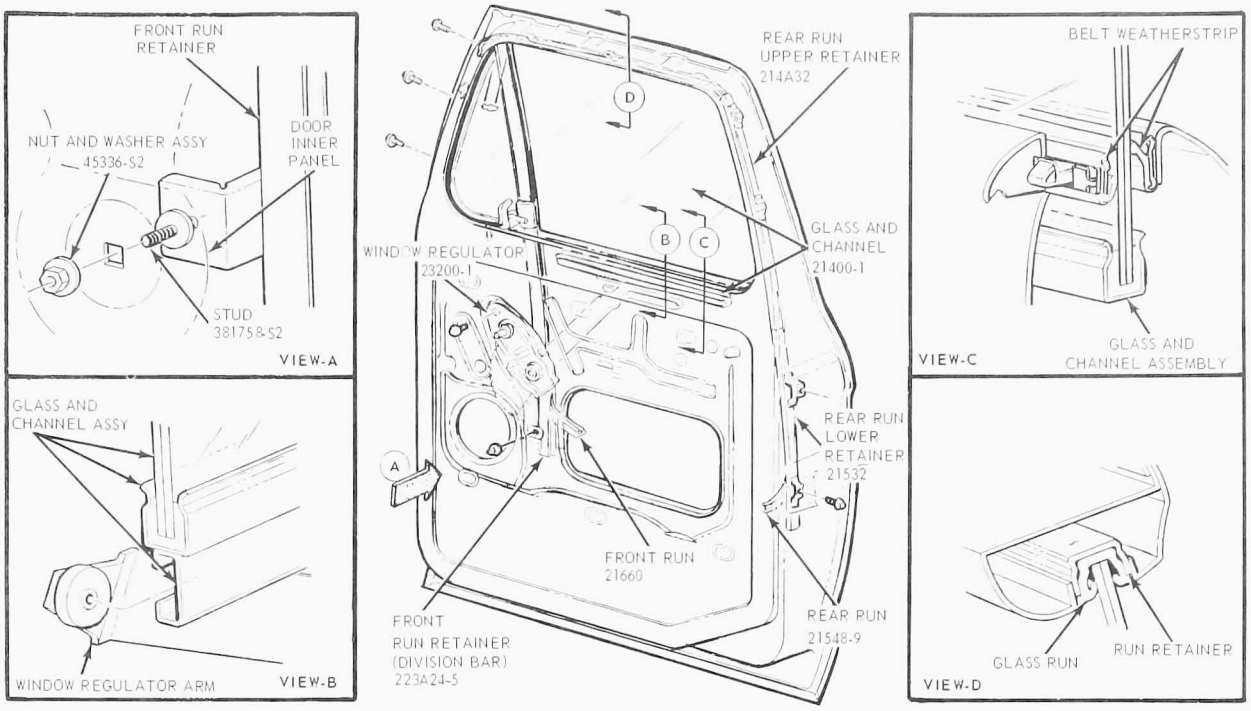

P1172-B

FIG. 6 Door Window Mechanism—F-Series

7. Remove two screws and nuts attaching the front run and division bar to the lower bracket (Fig. 11).
8. Remove the glass and channel from the door.
9. Remove the glass from the glass channel with the tool shown in Fig. 5.

Installation

1. Install the glass in the glass channel with the tool shown in Fig. 4.
2. Install the glass and channel in the glass runs.
3. Install the two front run and division bar attaching screws and nuts and adjust the front run snug against the glass.
4. Position the door latch and remote control to the door and install the latch attaching screws and nuts.
5. Position the upper inner panel to the door and the window regulator arms to the rollers in the glass channel. Then, install the retainers to retain the rollers on the window regulator arms.
6. Position the door latch remote control to the upper inner panel and install the attaching screws and nuts.
7. Position the upper inner panel to the door and install the attaching screws.
8. Install the door inside handle.
9. Position the lower inner panel and check strap to the door and install the attaching screws.
10. Check the operation of the door latch and window regulator.

FRONT DOOR WINDOW REGULATOR

ECONOLINE

Removal

1. Open the door and lower the window glass.
2. Remove one screw attaching the handle to the window regulator shaft and remove the handle.
3. Remove the access cover from the door inner panel.
4. Disconnect the regulator arm roller from the regulator arm by removing the roller retaining clip (Fig. 4).
5. Remove four screws attaching the window regulator to the door inner panel and remove the window regulator from the door.

Installation

1. Lubricate the window mechanism as shown in Part 42-02.
2. Position the regulator to the door inner panel and install the four attaching screws.
3. Insert the retaining clip on the roller and insert the roller in the glass channel.
4. Insert the window regulator arm pin in the roller and press firmly to lock the roller to the regulator arm.
5. Check the operation of the window mechanism and install the access cover on the door inner panel.

BRONCO

Removal

1. Remove the door inside handle, access cover plate or trim panel, and water shield.
2. Lower the door glass and remove the hairpin clip that secures the channel roller to the regulator arm (Fig. 2).
3. Slide the door glass to the top of the door and securely tape it in this position.
4. Crank the regulator assembly handle to raise the regulator arm to its highest position.
5. Remove the regulator assembly handle.
6. Remove the four screws that secure the regulator assembly to the door inner panel. Remove the regulator through the access hole opening.

Installation

1. Lubricate the new regulator assembly if necessary. Position the regulator assembly in the door, and secure it with four screws.
2. Install the regulator handle, and crank the handle until the regulator arm is in its lowest position.
3. Untape and lower the door glass and position the channel roller on the regulator arm and secure it with a hairpin clip.

4. Check the window operation. If the window glass does not raise or lower far enough, loosen the regulator assembly retaining screws and shift the regulator up or down as may be necessary.
5. Install the water shield, access cover plate or trim panel, and door handle.

F-SERIES

Removal

1. Remove the door trim panel.
2. Remove the three regulator assembly-to-door inner panel retaining screws (Fig. 6). Temporarily support the glass assembly in a half down position.
3. Remove the regulator assembly from the door by allowing the regulator arm roller to slide out of the channel on the glass lower frame.

Installation

1. Position the regulator assembly to the glass channel and to the door inner panel. Install the three regulator assembly retaining screws but do not tighten them.
2. Remove the temporary glass support and roll the window all the way down. The top edge of the glass should be about flush with the belt line. If adjustment is necessary, rotate the regulator down and forward to lower the glass, or up and rearward to raise the glass. Tighten the regulator attaching screws when the glass is about flush with the belt line.
3. Install the door trim panel.

L-SERIES

Removal

1. Remove the access panel from the door.
2. Remove the channel bracket retaining screws and remove the bracket (Fig. 7). Lower the glass to the bottom of the door.
3. Remove the regulator handle by removing the retaining screw.
4. Remove the two screws retaining the equalizer bracket to the door inner panel and remove the bracket.
5. Remove the regulator retaining screws and remove the regulator from the door.

Installation

1. Position the regulator to the door panel and install the retaining screws.
2. Install the channel bracket to the glass and channel assembly.
3. Install the equalizer bracket and connect the regulator arms rollers to the channel brackets.
4. Install the regulator handle.
5. Install the access panel.

C-SERIES

Removal

1. Remove the door access hole cover plate.
2. Lower the door glass, and disconnect the regulator arm from the glass channel roller by pulling the retaining clip (Fig. 8).
3. Raise the door glass and tape it in position.
4. Remove the window regulator handle.
5. Remove the regulator retaining screws, and remove the regulator through the access hole.

Installation

1. Lubricate the new regulator assembly, position the regulator in the door, and install the retaining screws.
2. Install the regulator handle, and crank the regulator arm to the lowered position.
3. Lower the door glass, assemble the roller assembly in the glass channel if it has been removed, and snap the regulator arm pin into the roller.
4. Check the door glass operation. If it does not close completely, or does not lower to the belt line, loosen the regulator retaining screws and shift the regulator up or down as may be

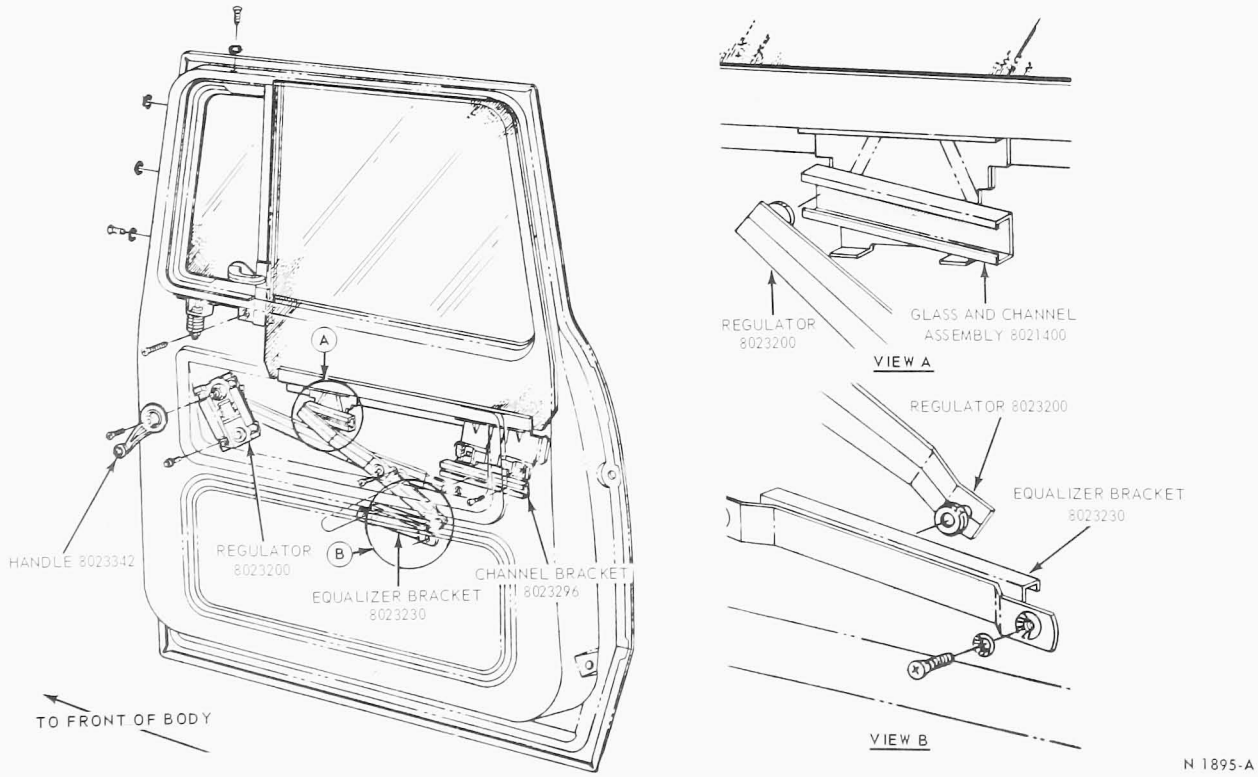

FIG. 7 Door Window Mechanism—All L-Series

necessary. Then, tighten the regulator retaining screws.
5. Run a bead of sealer around the access hole cover plate, and install the cover plate.

W-SERIES

Removal
1. Remove the check strap and the lower inner panel from the door.
2. Remove the door inner handle by pressing the escutcheon against the door and removing the retaining pin from the handle and shaft.
3. Remove the upper inner panel attaching screws. Then, pull the inner panel away from the door frame and remove the four screws, nuts, and washers attaching the door latch remote control to the inner panel (Fig. 10).
4. Lower the window and remove two clips retaining the roller assemblies to the window regulator arms, and pull the arms from the glass channel and rollers. Then, remove the upper inner panel and window regulator from the door.
5. With the upper inner panel on a bench, remove the window regulator handle as outlined in Step 2.
6. Remove four regulator attaching screws and remove the regulator from the upper inner panel.

Installation
1. Position the window regulator to the door upper inner panel and install the four attaching screws.
2. Position the upper inner panel to the door and remote control and install the four remote control attaching screws, washers, and nuts.
3. Position the regulator to the glass channel and rollers and install the roller retaining clips.
4. Install the upper inner panel attaching screws.
5. Install the window regulator and door inner handles.
6. Position the lower inner panel and check strap to the door and install the attaching screws.
7. Check the operation of the window regulator and close the door.

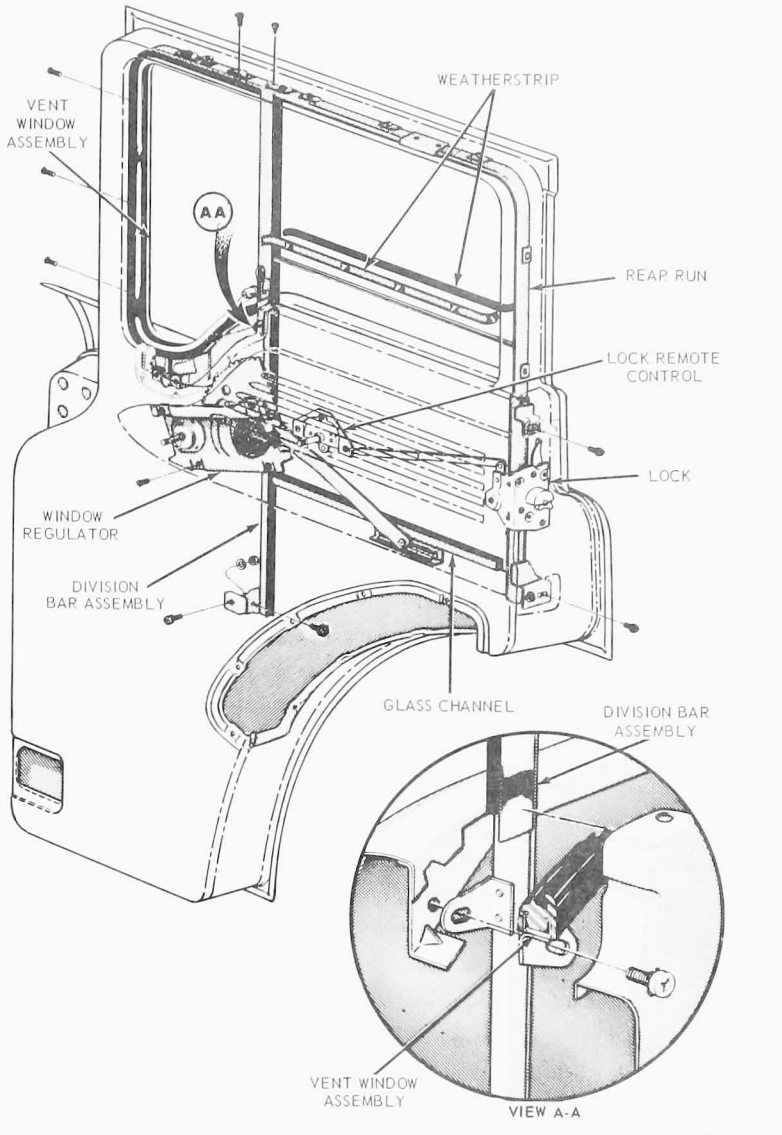

FIG. 8 Door Latch and Window Mechanism—C-Series

DOOR GLASS BELT WEATHERSTRIP

ECONOLINE

Removal
1. Remove the access cover from the door inner panel.
2. Disconnect the regulator arm roller from the regulator arm by removing the roller retainer clip (Fig. 4) and pulling the arm from the roller. Allow the glass to rest at the bottom of the runs.
3. Unsnap and remove the belt line weatherstrip(s) from the door.

Installation
1. Position the weatherstrip to the door and snap into place.
2. Insert the retaining clip on the regulator arm roller and insert the roller in the glass channel.
3. Insert the window regulator arm pin in the roller and press firmly to lock the roller on the regulator arm.
4. Install the access cover on the door inner panel.

GLASS REAR RUN

BRONCO

1. Remove the trim or access panel from the door.

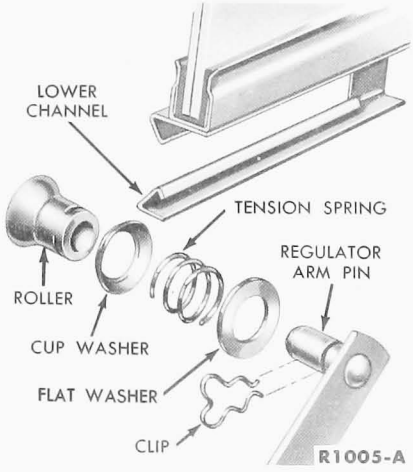

FIG. 9 Channel Roller Assembly—C-Series

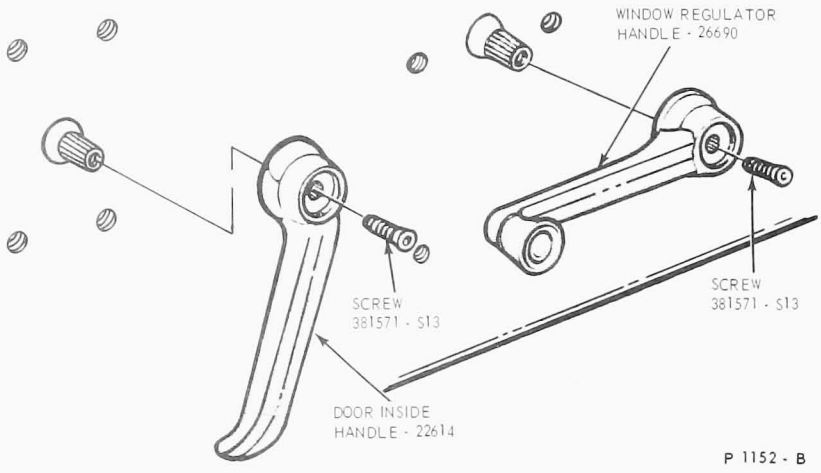

FIG. 10 Door and Window Handle Installation—W-Series

2. Raise the glass to the full up position.
3. Remove two screws attaching the run to the rear edge of the door (Fig. 2), and remove the run from the door.
4. Position the rear run into the door, and install the two attaching screws.
5. Adjust the rear run and install the door trim panel.

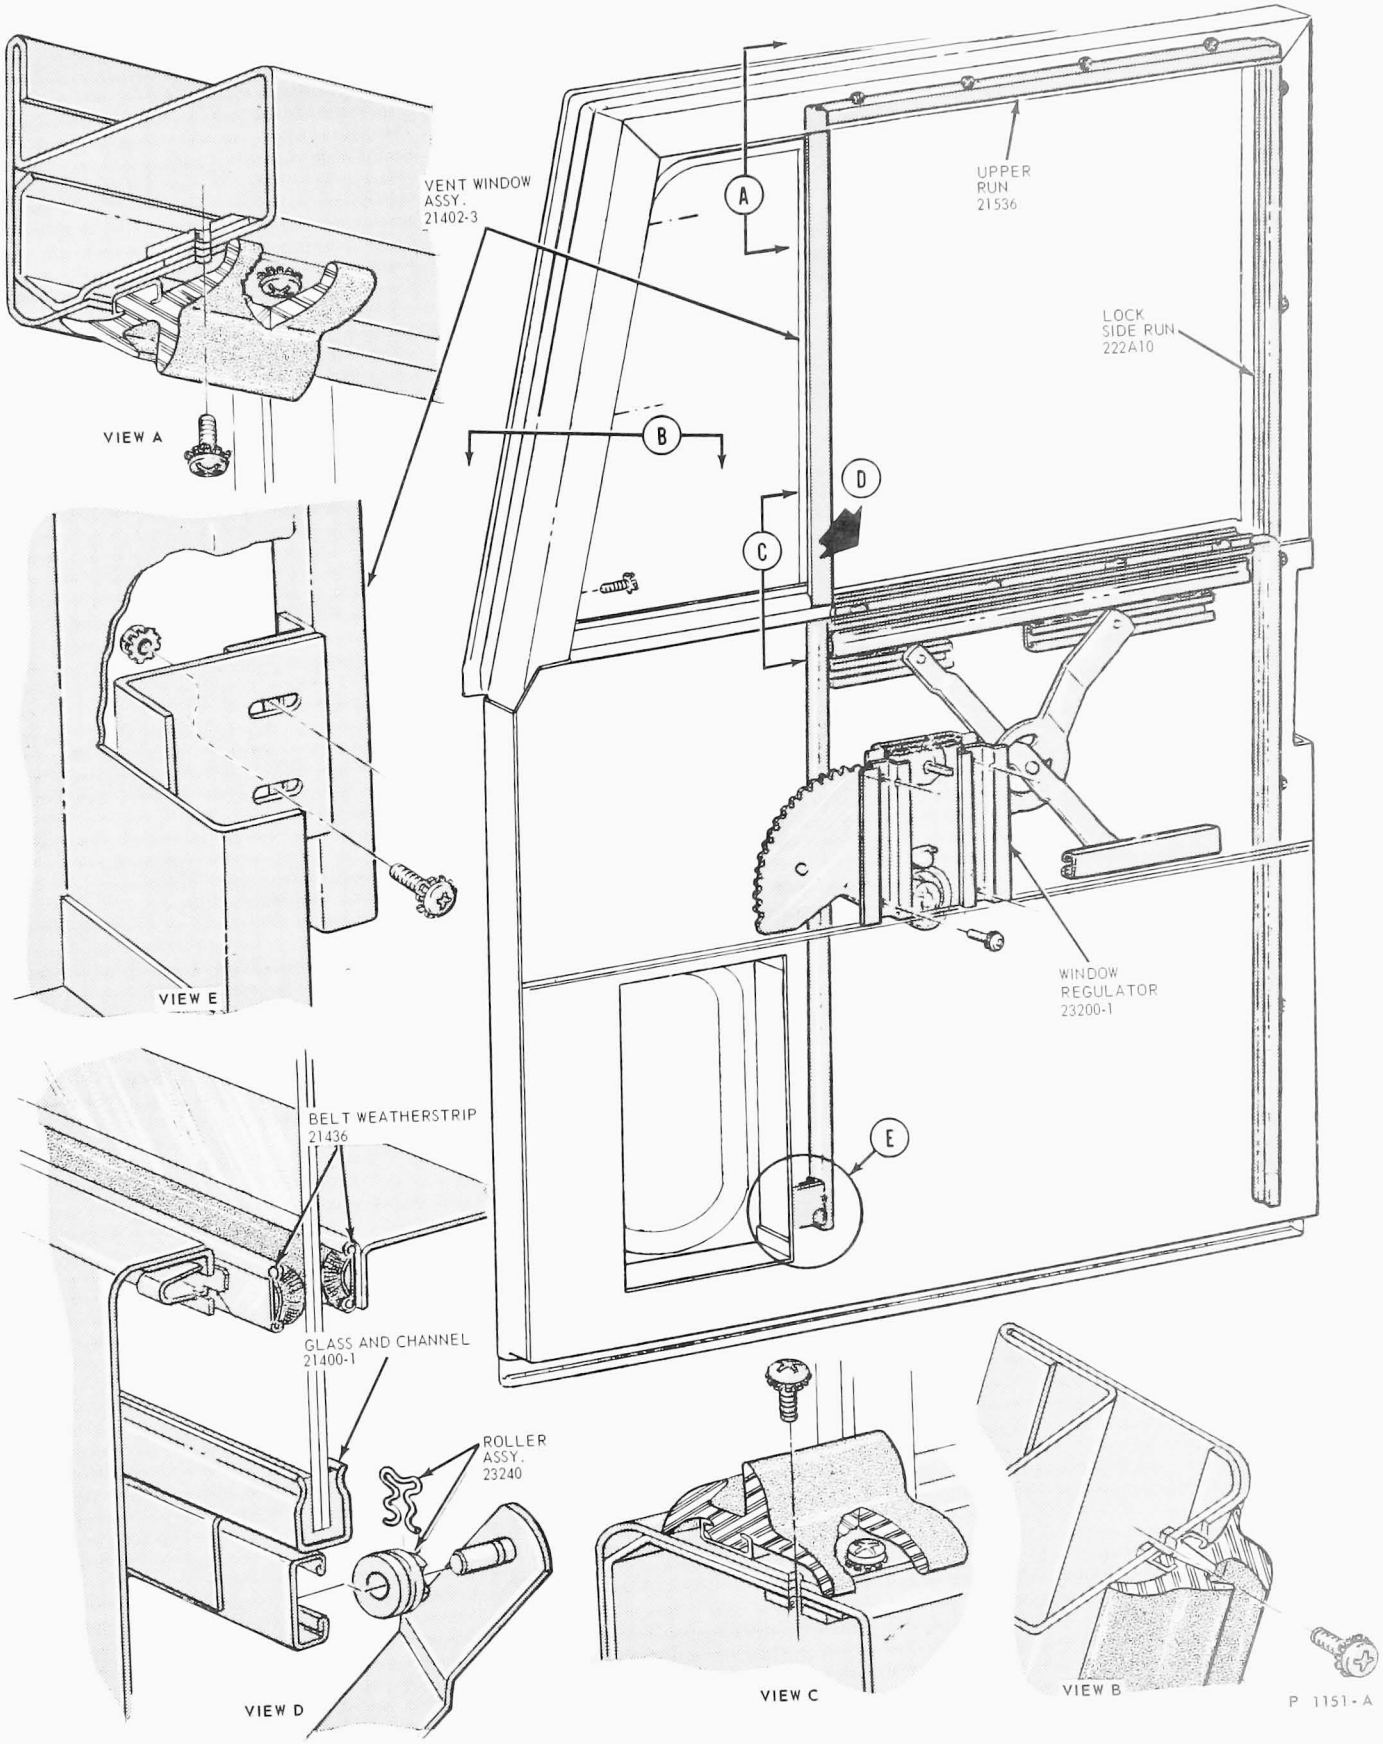

FIG. 11 Door Window Mechanism—W-Series

PART 42-15 Vent Window Mechanism

COMPONENT INDEX Applies to Models ad Indicated	MODEL APPLICATION							
	All Models	Bronco	Econoline	F-Series	L-Series	C-Series	W-Series	B-Series
REMOVAL AND INSTALLATION								
Frame Assembly – Vent Window		15-01	15-01	15-02	15-02	15-02	15-03	
Glass – Vent Window		15-01	15-01	15-01	15-01		15-01	

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the items is not applicable to the vehicle(s) listed.

REMOVAL AND INSTALLATION

VENT WINDOW GLASS

ALL EXCEPT C-SERIES

Removal

1. Open the vent window.
2. Push the glass from the glass frame with the tool shown in Fig. 1.
3. Clean the glass frame of tape and sealer.

Installation

1. Apply sealer to the glass frame.
2. Install the glass and new tape in the glass frame with the tool shown in Fig. 1.
3. Trim the excess edges of the tape around the glass frame and clean the glass and surrounding area.

VENT WINDOW GLASS FRAME

W-SERIES

Refer to Figs. 9 and 10, Part 42-04.

Removal

1. Remove the check strap and the lower inner panel from the door.
2. Remove the door inside handle by pressing the escutcheon against the door and removing the retaining pin from the handle and shaft.
3. Remove the upper inner panel attaching screws. Then, pull the inner panel away from the door frame and remove the four remote control attaching screws and nuts.
4. Lower the glass and remove the clips retaining the roller assemblies to the window regulator arms. Pull the arms from the glass channel and rollers. Then, remove the upper inner panel and window regulator from the door.
5. Remove the vent window adjustment nut and spring from the vent window lower pivot. Then, press the vent window glass and frame downward to release the upper pivot and remove the vent window and frame from the door.

Installation

1. Position the vent window glass and frame in the opening and engage the upper pivot. Install the spring and adjustment nut on the lower pivot and tighten for the desired tension.
2. Position the upper inner panel to the door and the window regulator arms to the rollers in the glass channel. Then, install the retainers to retain the rollers on the window regulator arms.
3. Position the remote control to the upper inner panel and install the attaching screws and nuts.
4. Position the upper inner panel to the door and install the attaching screws.
5. Install the door inside handle.
6. Position the lower inner panel and check strap to the door and install the attaching screws.
7. Check the operation of the door latch, window regulator and the vent window.

GLASS AND CHANNEL REMOVAL TOOL (NO. 2900) AVAILABLE FROM SOMMER AND MALA GLASS MACHINE COMPANY, 5501 W. OGDEN AVENUE, CHICAGO 50, ILLINOIS

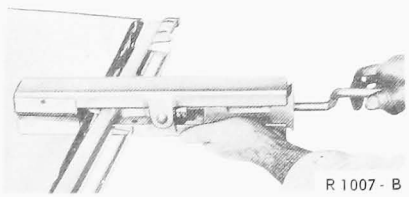

FIG. 1 Vent Glass Replacement

VENT WINDOW ASSEMBLY

BRONCO

Removal

1. Remove the trim panel or door access panel from the door.
2. Remove the glass lower stop from the door.
3. Lower the glass and remove the belt inner and outer weatherstrips.
4. Pull the glass top run down and away from the vent window assembly.
5. Remove four screws attaching the vent window assembly to the door frame (Fig. 2, Part 42-04).
6. Remove one screw attaching the vent window assembly to the door at the belt line near the division bar.
7. Tilt the vent window assembly rearward and remove the assembly from the door.

Installation

1. Position the vent window assembly in the door. Be sure the division bar is properly seated in the top end of the front run (Fig. 2, Part 42-04).
2. Install the five screws attaching the vent window assembly to the door.
3. Insert the glass top run into the recess along the top of the door.
4. Install the belt inside and outside weatherstrips.
5. Install the glass lower stop. Then, install the access or trim panel on the door.

ECONOLINE

Refer to Fig. 3, Part 42-04.

Removal

1. Remove the access cover from the door inner panel.
2. Remove three screws attaching the vent window assembly to the upper leading edge of the door.

3. Remove one screw attaching the vent window assembly to the door at the belt line.
4. Remove one screw attaching the front run retainer and division bar bracket to the door.
5. Slide the front run out of the front run retainer and division bar.
6. Disconnect the regulator arm roller from the regulator arm by removing the roller retaining clip and pulling the arm from the roller.
7. Unsnap and remove the belt line weatherstrips from the door.
8. Pull the rear run down and out of the run slot along the top of the glass opening.
9. Tilt the vent window and division bar assembly rearward and separate the vent window from the front run retainer and division bar. Then, remove the vent window and the front run retainer and division bar from the door.
10. Remove two screws attaching the vent window upper pivot to the vent window frame.
11. Remove the nut, spring, spacer and bushing from the vent window lower pivot. Then, separate the vent window glass and frame from the vent window frame.
12. To remove the weatherstrip, remove two screws from the top of the vent window frame. Then, straighten the weatherstrip retaining tabs and remove the weatherstrip.

Installation

1. Position the weatherstrip to the vent frame and bend the retaining tabs down to retain the weatherstrip. Install the two screws at the top of the vent frame.
2. Position the glass frame to the vent frame and install spacer, bushing, spring and nut on the vent window lower pivot. Adjust the spring tension to hold the vent window in any position at highway speeds.
3. Position the vent window upper pivot to the glass frame pivot and vent frame and install the two attaching screws.
4. Position the vent window and the front run retainer and division bar in the door. Then, insert the front run retainer and division bar in the rear edge of the vent window.
5. Position the glass and channel assembly in the front run retainer and division bar. Then, place the vent window assembly into position in the door, and install three screws attaching the vent frame to the upper leading edge of the door.
6. Install the belt line weatherstrips.
7. Insert the rear run into the slot along the top edge of the window opening.
8. Insert the retaining clip on the regulator arm roller and insert the roller in the glass channel.
9. Insert the window regulator arm pin in the roller and press firmly to lock the roller on the regulator arm.
10. Insert the front run in the front run retainer and division bar.
11. Install the screw attaching the front run retainer and division bar bracket to the door.
12. Install the vent window attaching screw at the belt line.
13. Adjust the window glass runs.
14. Install the access cover on the door inner panel.

F-SERIES

Refer to Fig. 6, Part 42-04.

Removal

1. Remove the door trim panel retaining screws and remove the door trim panel.
2. Remove the adjusting nut and washer that retains the division bar to the door inner panel.
3. Remove the three screws that attach the vent assembly to the leading edge of the door.
4. Lower the door glass.
5. Pull the top weatherstrip part way out of the door window frame in the division bar area.
6. Tilt and remove the vent window and division bar assembly from the door.
7. Separate the run and retainer from the vent window division bar.
8. Remove two vent upper pivot-to-vent frame screws.
9. Remove the retaining nut and tension spring from the vent window lower pivot.
10. Separate the vent glass retainer and the pivot stops from the vent frame and weatherstrip assembly.

Installation

1. Position the vent glass retainer assembly with the pivot stops into the vent window frame and weatherstrip assembly.
2. Install the two upper pivot-to-frame retaining screws.
3. Install the pivot tension spring and retaining nut. Adjust spring tension so that the vent will stay open at highway speeds.
4. Position the run and retainer assembly in the vent window assembly.
5. Position the vent window and division bar assembly into the door and to the glass edge.
6. Install the three vent window frame-to-leading edge of door window frame retaining screws.
7. Position the weatherstrip back into the door window frame (division bar area).
8. Install the division bar lower run-to-door inner panel adjusting screw washer and nut (adjust the run for proper door window operation).
9. Install the door trim panel.

L-SERIES

Removal

1. Remove the access panel from the door.
2. Remove the bolt retaining the bottom of the run retainer to the retainer bracket. (Fig. 2).
3. Remove the division bar retaining screw from the door inner panel at the belt line.
4. Remove the four screws retaining the vent window assembly to the door frame.
5. Remove the channel bracket retaining screws and remove the bracket. Remove the vent window assembly from the door (Fig. 2).
6. Place the vent assembly on a bench and pry the run retainer from the division bar.
7. Remove the top pivot screw from the frame assembly.
8. Remove the nut from the lower pivot. Also remove the nut, spring and nylon bushing.
9. Remove the glass assembly, washer and nylon bushing from the frame.
10. Remove the weatherstrip from the frame retainer assembly.
11. Drill out the four rivets retaining the division bar to the retainer and remove the division bar.

Installation

1. Position the division bar to the retainer and install the four rivets.
2. Install the weatherstrip to the frame retainer.
3. Install the glass assembly, washer, nylon bushings and springs. Adjust the spring tension and install the lower pivot nut.
4. Install the top pivot screw.
5. Snap the run retainer into place on the frame assembly.
6. Position the vent window assembly in the door and install the four retaining screws in the door frame. Also install the division bar retaining screw at the belt line.
7. Position the door glass and install the channel bracket.
8. Install the front run retainer in the retainer brackets.
9. Install the access panel.

C-SERIES

Refer to Fig. 7, Part 42-04.

1. Remove the door access hole cover plate. Remove the lower front garnish moulding from just below the vent window.

2. Remove the screws retaining the top of the division bar to the door window frame. Remove the screw retaining the center of the division bar, run assembly, and vent window frame retainer assembly to the inner panel. (View AA, Fig. 7, Part 42-04).
3. Remove the bolts retaining the division bar lower end to the mounting bracket on the door.
4. Lower the door window glass.
5. Remove the screws retaining the vent window and frame retainer to the front of the door frame. Pull the rear upper run out of the door frame at the division bar.
6. Remove the pivot screws retaining the vent frame and clamp to the vent window frame retainer assembly, and remove the vent window and frame assembly.
7. Remove the vent window weatherstrip from the frame and the door.
8. Install the weatherstrip on the vent window frame and door. Position the vent window frame assembly to the frame retainer assembly and install the pivot retaining clamp and screws.
9. Position the vent window and frame retainer assembly to the door frame and install the screws. Snap the upper rear run in place.
10. Install the bolts retaining the division bar lower end to the mounting bracket on the door.
11. Install the screw retaining the center of the division bar, run assembly and vent window frame retainer assembly to the inner panel. Install the screw retaining the top of the division bar to the door window frame.
12. Adjust the division bar for proper glass operation and tighten the division bar retaining screws and bolts.
13. Install the door access hole cover plate and lower front garnish moulding.

W-SERIES

Refer to Figs. 9 and 10, Part 42-04.

Removal

1. Remove the check strap and the lower inner panel from the door.
2. Remove the door inside handle by pressing the escutcheon against the door and removing the retaining pin from the handle and shaft.
3. Remove the upper inner panel attaching screws. Then, pull the inner panel away from the door frame and remove the four remote control attaching screws and nuts.

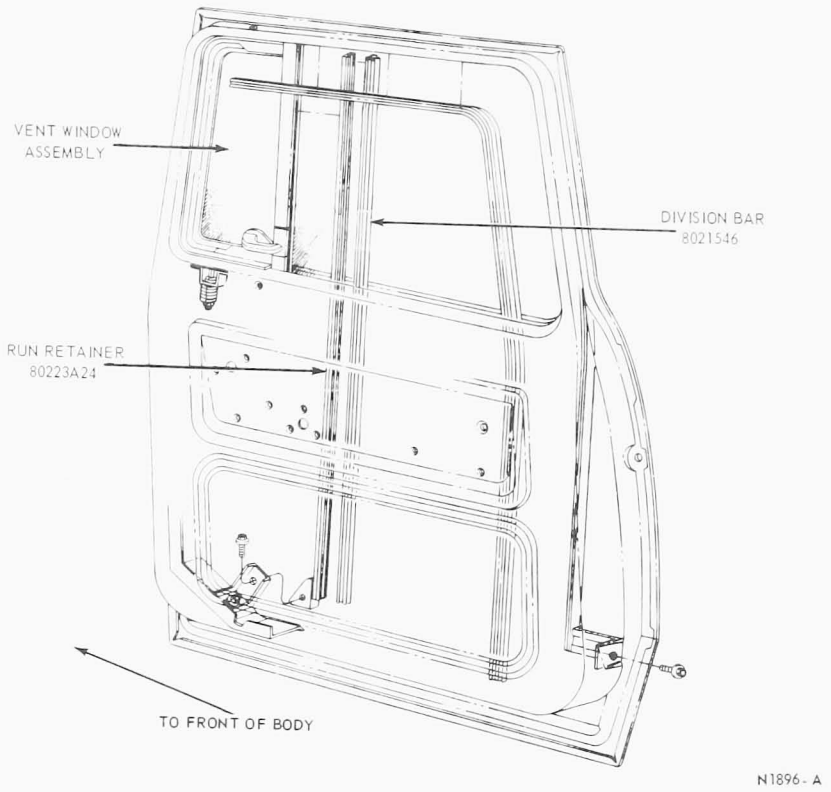

FIG. 2 Vent Window Assembly—L-Series

4. Lower the window and remove the clips retaining the roller assemblies to the window regulator arms and pull the arms from the glass channel and rollers. Then, remove the upper inner panel and window regulator from the door.
5. Remove the screws attaching the remote controls and the door latch to the door panel and remove the latch and remote controls from the door.
6. Remove two screws and nuts attaching the lower end of the division bar glass front run to the door.
7. Remove the glass and channel from the door.
8. Remove two screws attaching the top of the division bar and glass run to the door.
9. Pull the vent window weatherstrip from the retainer and remove three screws attaching the retainer to the door. Then, remove the division bar, vent window and weatherstrip from the door.

Installation

1. Position the division bar, vent window and weatherstrip to the door and install the three weatherstrip retainer attaching screws.
2. Position the door glass in the runs and install the two division bar and front run lower attaching screws and nuts.
3. Install the two division bar and glass run upper attaching screws.
4. Adjust the lower end of the division bar and glass run for a snug fit against the door glass. Then, tighten the two attaching screws and nuts.
5. Position the door latch and remote controls to the door and install the attaching screws and nuts.
6. Position the upper inner panel to the door and the window regulator arms to the rollers in the glass channel. Then, install the retainers to retain the rollers on the window regulator arms.
7. Position the remote control to the upper inner panel and install the attaching screws and nuts.
8. Position the upper inner panel to the door and install the attaching screws.
9. Install the door inside handle.
10. Position the lower inner panel and check strap to the door and install the attaching screws.
11. Check the operation of the door latch, window regulator and vent window.

PART 42-25 Pivot Type Rear Door and Side Window

REMOVAL AND INSTALLATION

MOVABLE GLASS—SLIDING DOOR

ECONOLINE AND CLUB WAGON

1. Remove one screw attaching each window prop to the door.
2. Remove three screws attaching the glass frame to the glass opening, and remove the glass and frame, weatherstrip and latch from the door (Fig. 1).
3. Remove the latch handle from the glass and install on new glass, if the frame is to be replaced (Fig. 1).
4. Position the glass and frame to the glass opening and install the three attaching screws.
5. Position the window props to the door and install the attaching screws.

MOVABLE GLASS—EXCEPT SLIDING DOOR

ECONOLINE AND CLUB WAGON

1. Remove three screws attaching the window latch plate to the inner panel.
2. Remove three screws attaching the window glass frame to the body opening, and remove the glass and frame, weatherstrip, and latch from the vehicle (Fig. 2).
3. Remove the latch from the window frame and install on the new frame, if the frame is to be replaced.
4. Position the glass and frame assembly to the body opening and install the three attaching screws.
5. Position the latch plate to the inner panel and install the three attaching screws.

REMOVAL AND INSTALLATION

WINDSHIELD

F-AND L-SERIES

Removal

1. Remove the windshield wiper arms and blades.
2. Remove the inside rear view mirror and bracket.
3. Loosen the weatherstrip around the windshield opening.
4. Push the windshield glass, and mouldings (if so equipped) out of the windshield opening.
5. Remove the mouldings (if so equipped) from the weatherstrip (Fig. 1).
6. Remove the weatherstrip from the glass.
7. Clean the glass and/or weatherstrip of all old sealer if either is to be re-used.

Installation

1. Clean the windshield opening flange to remove all old sealer or other foreign material.
2. Apply sealer (19563) to the windshield opening flange.
3. Position the weatherstrip on the windshield.
4. Insert a draw cord in the pinch weld opening of the weatherstrip all around the weatherstrip. Overlap the cord about 18 inches at the lower center of the glass. Tape the ends of the cord to the glass as shown in Fig. 2.
5. Coat the weatherstrip mounting surfaces with rubber lubricant (19583). Position the mouldings on the weatherstrip (Fig. 1).
6. Position the windshield and weatherstrip to the windshield opening.
7. With an assistant applying hand pressure to the outside of the windshield, pull the draw cord to pull the lip of the weatherstrip over the windshield opening flange. Draw the weatherstrip lip over the lower flange, each side of the flange, and then over the upper flange.
8. Install the rear view mirror and bracket.
9. Clean the glass and surrounding area.
10. Install the windshield wiper arms and blades.

C-SERIES

Removal

This series truck has a two-piece windshield. Therefore, the following procedures apply to only one-half of the windshield. The procedures apply to custom cab models. When working on a standard cab, skip the steps regarding outside mouldings.

1. Remove the windshield wiper arm assembly.
2. Snap the upper and lower joint covers off the mouldings at the center.
3. Remove the windshield garnish lower moulding.
4. Start at the upper center corner, pull down the weatherstrip, and push the windshield and weatherstrip out of

the opening.
5. Remove the weatherstrip from the glass, and remove the outside mouldings from the weatherstrip.
6. Clean the windshield opening mounting flange, and repair any wavy areas as necessary.
7. Clean the weatherstrip with cleaning solvent to remove all old sealer and cement. Install the outside mouldings in the weatherstrip.
8. Apply caulk and sealer (19563) to the weatherstrip and the opening flange.
9. Install the weatherstrip on the glass, and install a draw cord in the weatherstrip flange slot all around the weatherstrip and let it overlap at the bottom center. Coat the weatherstrip mounting surfaces with rubber lubricant.
10. Position the windshield and weatherstrip assembly in the opening. With a helper applying hand pressure from outside, start at the inside bottom center and pull the weatherstrip lip over the flange with the draw cord (Fig. 2).
11. Install the windshield lower garnish moulding, the windshield wiper arm assembly, and the upper and lower center joint covers.
12. Water test the installation for leaks, and seal with additional caulk and sealer if necessary.

W-SERIES

Removal
1. Remove the windshield wiper arm and blade assemblies.
2. Unlock the weatherstrip around the entire perimeter of the windshield (Fig. 3).
3. Working from inside the vehicle, push the windshield from the weatherstrip and remove the windshield from the vehicle.
4. Remove the weatherstrip from the glass opening and division bar.

Installation
1. Position the weatherstrip to the windshield opening and division bar.
2. Apply rubber lube to the weatherstrip and insert the windshield in the weatherstrip groove.
3. Lock the windshield weatherstrip (Fig. 3), and clean the windshield, weatherstrip, and body around the windshield.
4. Install the windshield wiper arms and blades.

ECONOLINE

Removal
1. Remove the windshield wiper arm and blades from the vehicle.
2. Starting at the inside top of the windshield, push the windshield and weatherstrip from the windshield opening.
3. Remove the weatherstrip and mouldings (if so equipped) from the windshield glass.
4. Remove all old sealer from the weatherstrip and windshield opening flange.

Installation
1. Apply sealer (19554) in the glass opening groove of the weatherstrip.
2. Position the weatherstrip on the glass and position the mouldings (if so equipped) in the weatherstrip (Fig. 4).
3. Install a pull cord (1/8 inch sash cord) in the body opening groove of the weatherstrip. Overlap the cord about 18 inches at the lower center of the glass and tape the ends of the cord to the inside of the glass (Fig. 2).
4. Apply sealer (19554) to the windshield opening flange.
5. Position the windshield and weatherstrip to the body opening.
6. With an assistant applying hand pressure from the outside, pull the draw cord to pull the lip of the weatherstrip over the windshield opening flange. Draw the

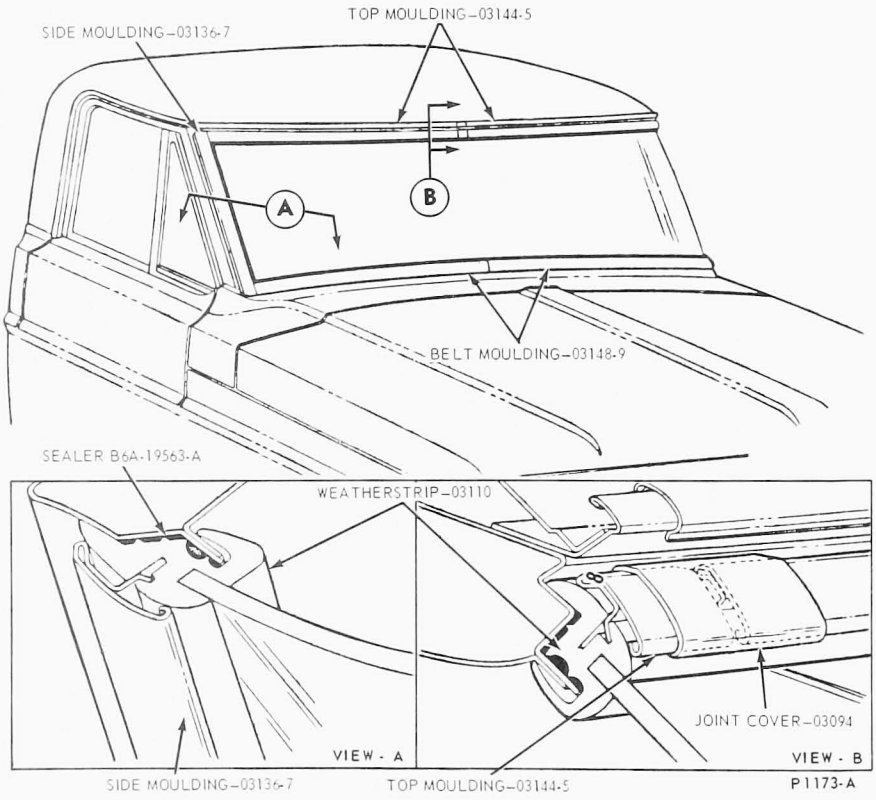

FIG. 1 Windshield Installation—F-Series Shown—L-Series Typical

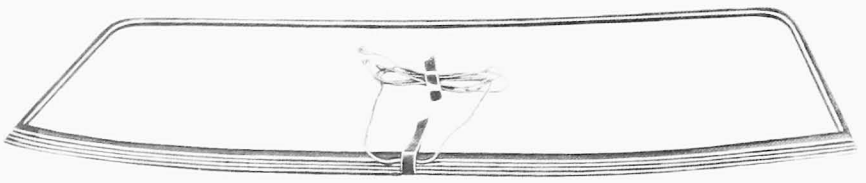

P1189 A

FIG. 2 Draw Cord Installed—Typical

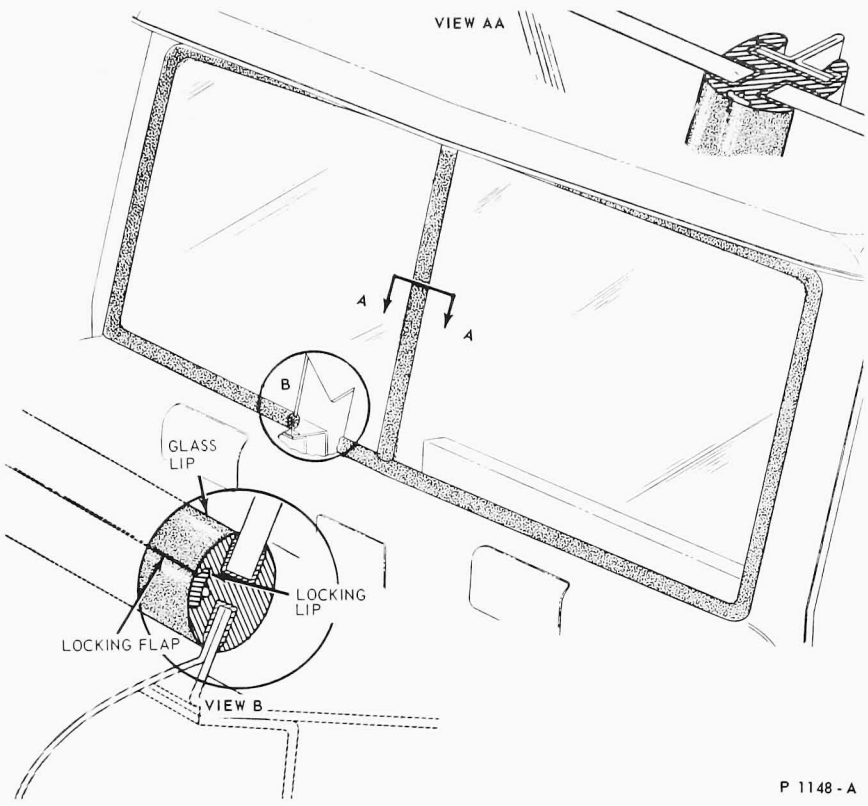

FIG. 3 Windshield Installation—W-Series—C-Series Typical

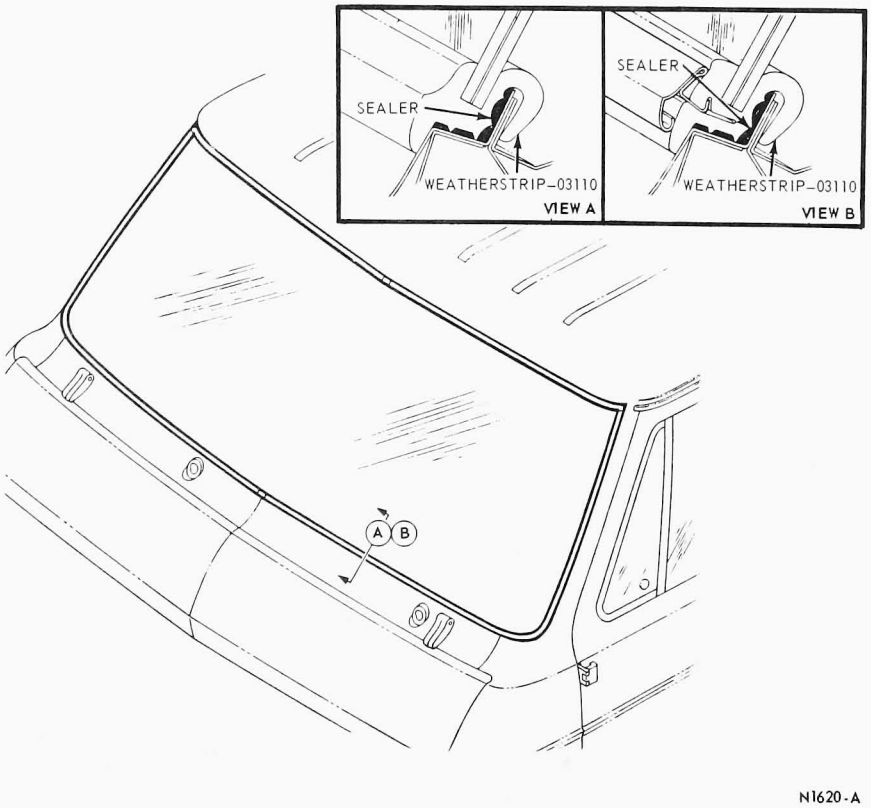

FIG. 4 Windshield Installation—Econoline

weatherstrip over the lower flange, each side flange, and then over the upper flange.
7. Clean all excess sealer from the windshield, weatherstrip and surrounding areas.
8. Install the windshield wiper arms and blades and test for water leaks.

BRONCO

Removal

1. Remove the windshield wiper arms and blades.
2. On roofless vehicles, ensure that the windshield is held securely in position by the two locking knobs on the dash panel.
3. Working from inside the vehicle, starting at the upper left corner and working across the top, pull the weatherstrip out of the glass opening (Fig. 5).
4. Remove the weatherstrip from the glass.

Installation

1. Clean the weatherstrip with cleaning solvent.
2. Clean the glass opening, check for wavy areas, and repair as necessary.
3. Run a bead of sealer around the opening flange crevice and in the inner flange crevice of the weatherstrip. Apply rubber lube to the weatherstrip lip.
4. Install the weatherstrip on the glass, and install a draw cord in the weatherstrip flange slot, all around the glass, letting it overlap at the bottom center.
5. Position the windshield glass and weatherstrip in the windshield opening.
6. With a helper applying hand pressure from outside the cab, start at the bottom center from inside the cab and pull the weatherstrip lip over the windshield frame flange with the draw cord. Alternate from side to side, moving about 12 inches at a time, until the windshield is in place.
7. Install the wiper arms and blades.
8. Test for water leaks.

BACK WINDOW

W-SERIES

1. Unlock the weatherstrip around the entire perimeter of the back window (Fig. 6).
2. Working from inside the vehicle, push the back window from the weatherstrip and remove the window from the cab.
3. Remove the weatherstrip from the back window opening.

4. Apply rubber lube to the weatherstrip and insert the back window in the weatherstrip groove.
5. Lock the back window in the weatherstrip (Fig. 6) and clean the back window glass, weatherstrip, and body around the back window.
6. Test for water leaks.

F-SERIES

Removal

1. Remove the outside mouldings from the weatherstrip, if so equipped (Fig. 7).
2. Push the back window glass and weatherstrip out of the window opening from inside the cab.
3. Remove the weatherstrip from the glass and clean all sealer from the weatherstrip and/or glass, if either is to be re-used.
4. Clean all sealer from the back window opening.

Installation

1. Position the weatherstrip to the back window glass.
2. Install a draw cord all around the weatherstrip in the flange crevice, allowing the cord to overlap at the bottom center of the glass. Coat the weatherstrip mounting surface with rubber lube (19583).
3. Apply sealer to the back window opening as shown in Fig. 7.
4. Position the glass and weatherstrip to the window opening. With a helper applying hand pressure from outside the cab, pull the weatherstrip lip over the window opening flange with the draw cord. Pull the weatherstrip over the lower flange pulling one end of the cord at a time. Then, pull the seal over the side flanges and upper flange. Install the outside moulding.
5. Clean the glass and the area around the window to remove all excess sealer.
6. Test for water leaks.

L-AND C-SERIES

1. With a helper outside, loosen the weatherstrip (Fig. 8), and push the glass inward.
2. Remove the weatherstrip from the glass.
3. Clean the back window opening flange, and check the flange for wavy areas and repair as necessary.
4. Clean the weatherstrip with cleaning solvent to remove all the old sealer and cement.
5. Apply caulk and sealer in the glass crevice of the weatherstrip, and install it on the glass.
6. Run a bead of caulk and sealer around the opening flange and in the flange crevice in the weatherstrip.
7. Install a draw cord all around the weatherstrip in the flange crevice. Let the draw cord overlap at the bottom center. Apply rubber lube to the weatherstrip lip.
8. Position the glass assembly in the opening. With a helper applying hand pressure from the other side, draw the weatherstrip lip over the window opening lower flange, each side flange, and then over the upper flange.
9. Water test the installation for leaks. If leaks exist, apply additional caulk and sealer.
10. Clean the window and the surrounding area.

BRONCO

The following procedure applies to the liftgate window or the short or long roof rear window.

When removing or replacing one of the above windows, a helper must be employed to work outside the vehicle (Fig. 9).

Removal

1. Working from inside, start at one corner and work across the top of the glass, pulling the weatherstrip down and pushing the glass and weatherstrip outward until the helper can grasp the glass and lift it from the glass opening.
2. Remove the weatherstrip from the glass.

Installation

1. Clean the weatherstrip with cleaning solvent to remove all old sealer and cement.
2. Clean the glass opening flange on the weatherstrip, check the flange for wavy areas, and repair as necessary.
3. Apply sealer in the glass crevice of the weatherstrip and install it on the glass.
4. Run a bead of sealer around the opening flange crevice and in the inner flange crevice of the weatherstrip.

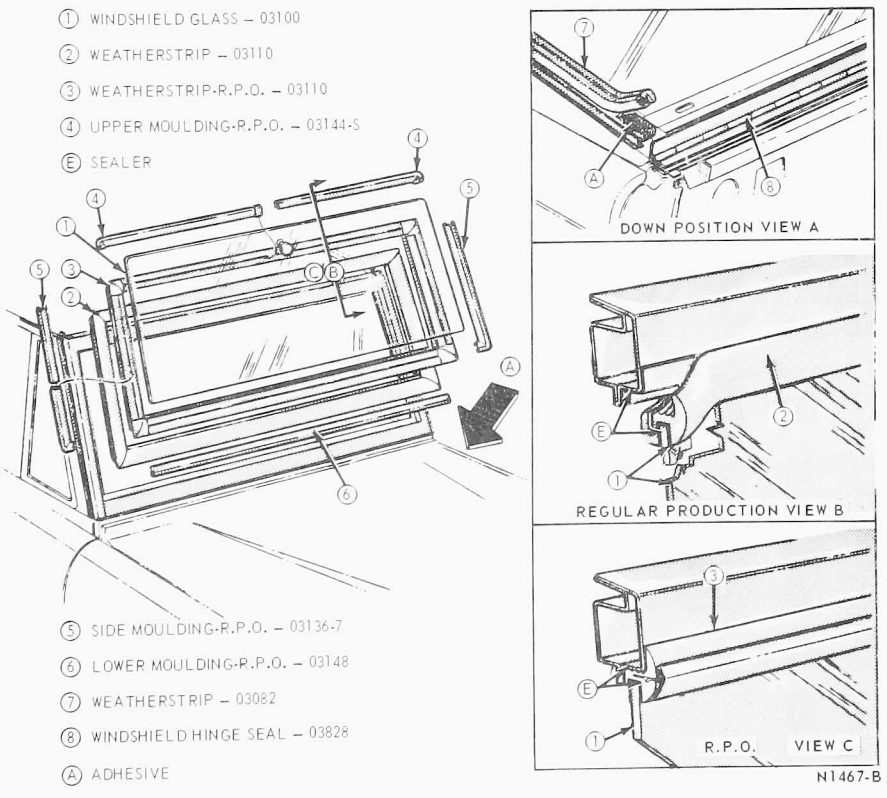

FIG. 5 Windshield Installation—Bronco

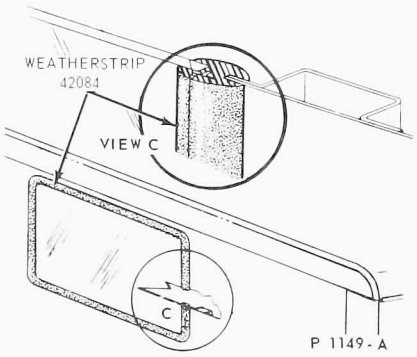

FIG. 6 Back Window Installation—W-Series

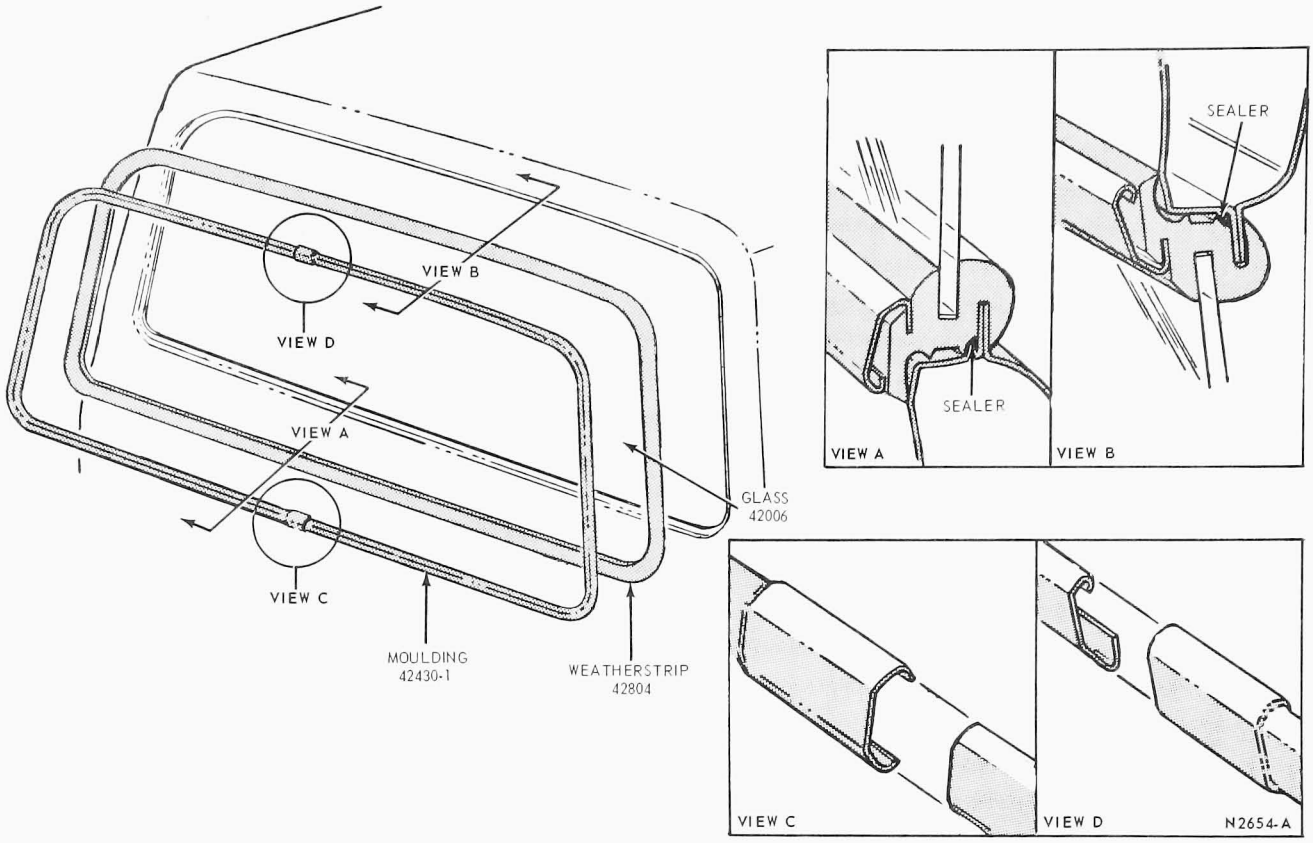

FIG. 7 Stationary Back Window Glass Installation—F-Series

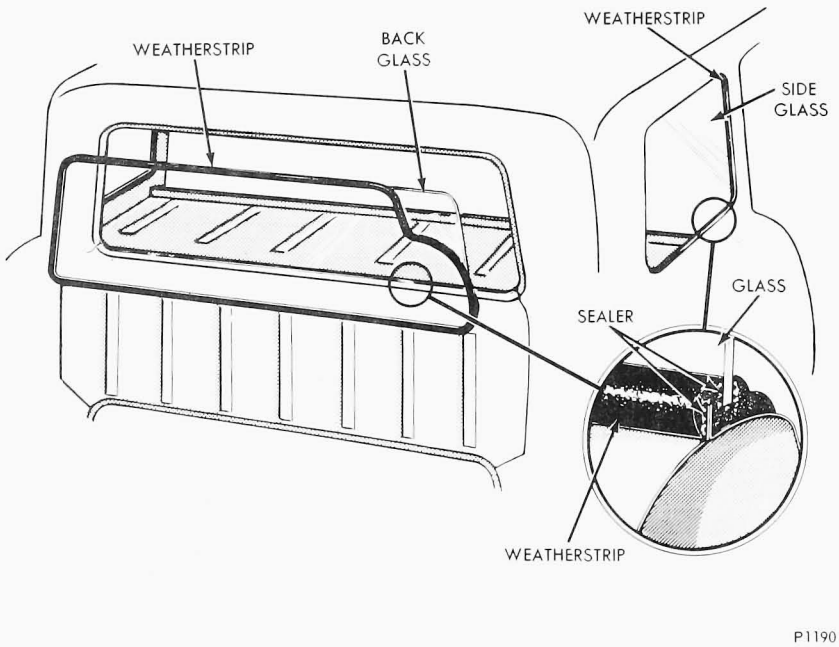

FIG. 8 Back Window Glass Installation—C-Series Shown— L-Series Typical

5. Install a draw cord all around the weatherstrip in the flange crevice. Let the draw cord overlap at the bottom center. Apply rubber lube to the weatherstrip lip.
6. Have a helper position the window assembly in the window opening and apply hand pressure on the glass. From the inside, draw the lip of the weatherstrip over the window opening lower flange with a draw cord. Alternate from side to side, moving about 12 inches at a time, until the window is in place.
7. Water test the installation for leaks, and seal with additional caulk and sealer if necessary.

QUARTER WINDOW GLASS

BRONCO

The following procedure is for replacement of the long roof side window glass.

When removing or replacing the glass, a helper must be employed to work outside the vehicle.

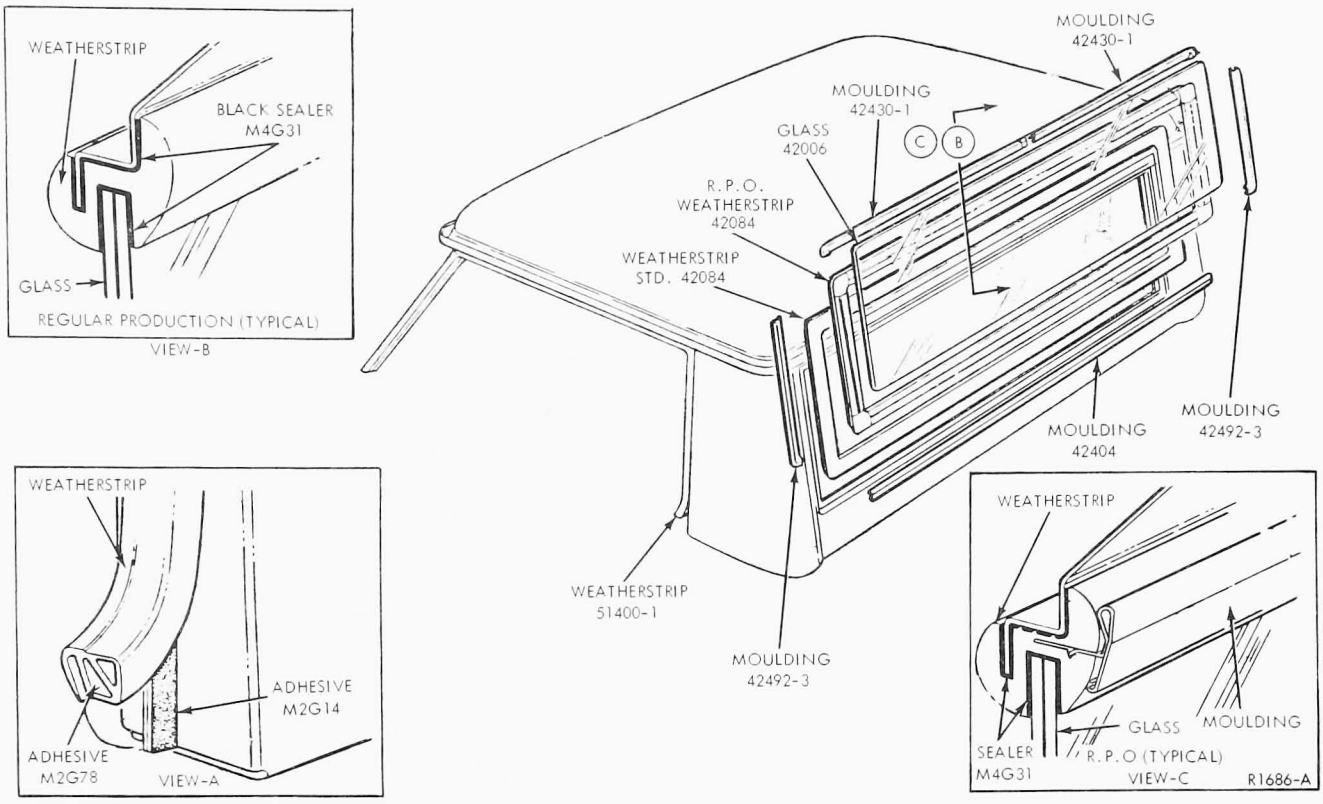

FIG. 9 Back Window Glass Installation—Bronco

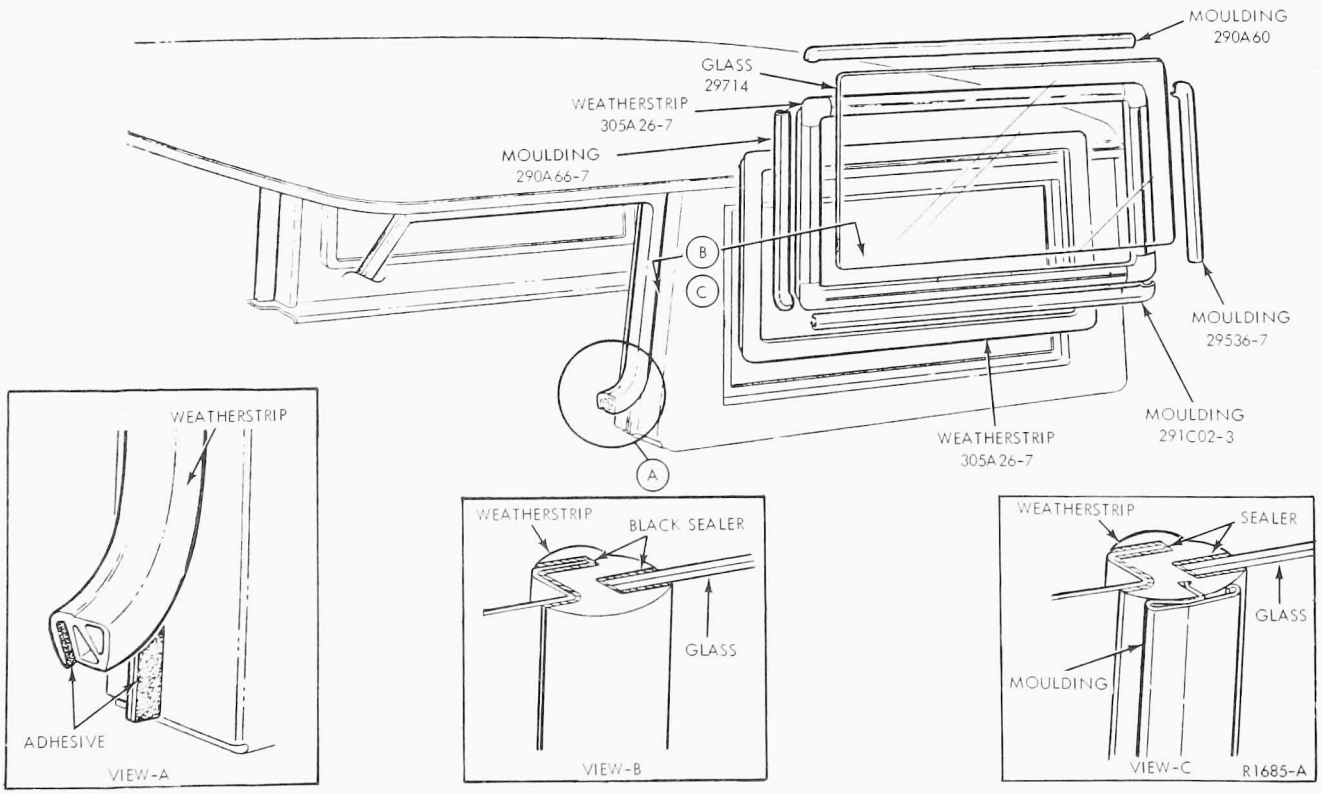

FIG. 10 Quarter Window Installation—Bronco

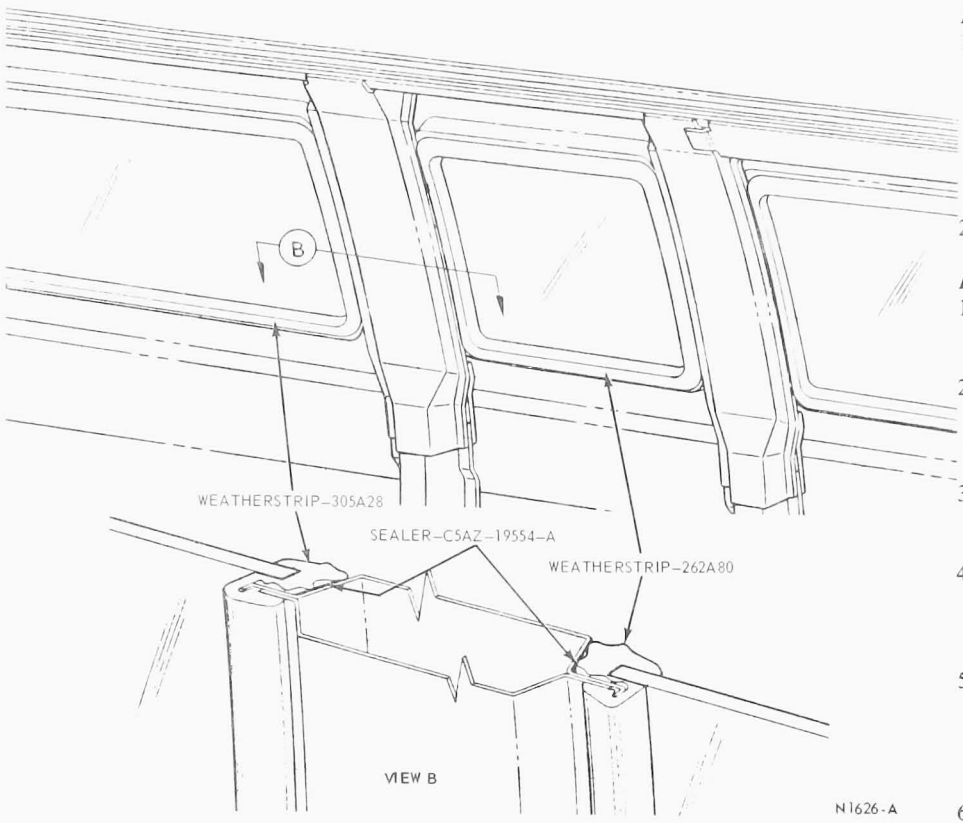

FIG. 11 Body Side and Rear Stationary Window Installation—Econoline

Removal

1. Working from inside, start at one corner and work across the top of the glass, pulling the weatherstrip down and pushing the glass and weatherstrip outward until the helper can grasp the glass and lift it from the glass opening.
2. Remove the weatherstrip from the glass (Fig. 10).

Installation

1. Clean the weatherstrip with cleaning solvent to remove all old sealer and cement.
2. Clean the glass opening flange on the weatherstrip, check the flange for wavy areas, and repair as necessary.
3. Apply sealer in the glass crevice of the weatherstrip and install it on the glass.
4. Run a bead of sealer around the opening flange crevice and in the inner flange crevice of the weatherstrip. See Fig. 10.
5. Install a draw cord all around the weatherstrip in the flange crevice. Let the draw cord overlap at the bottom center. Apply rubber lube to the weatherstrip lip.
6. Have a helper position the window assembly in the window opening and

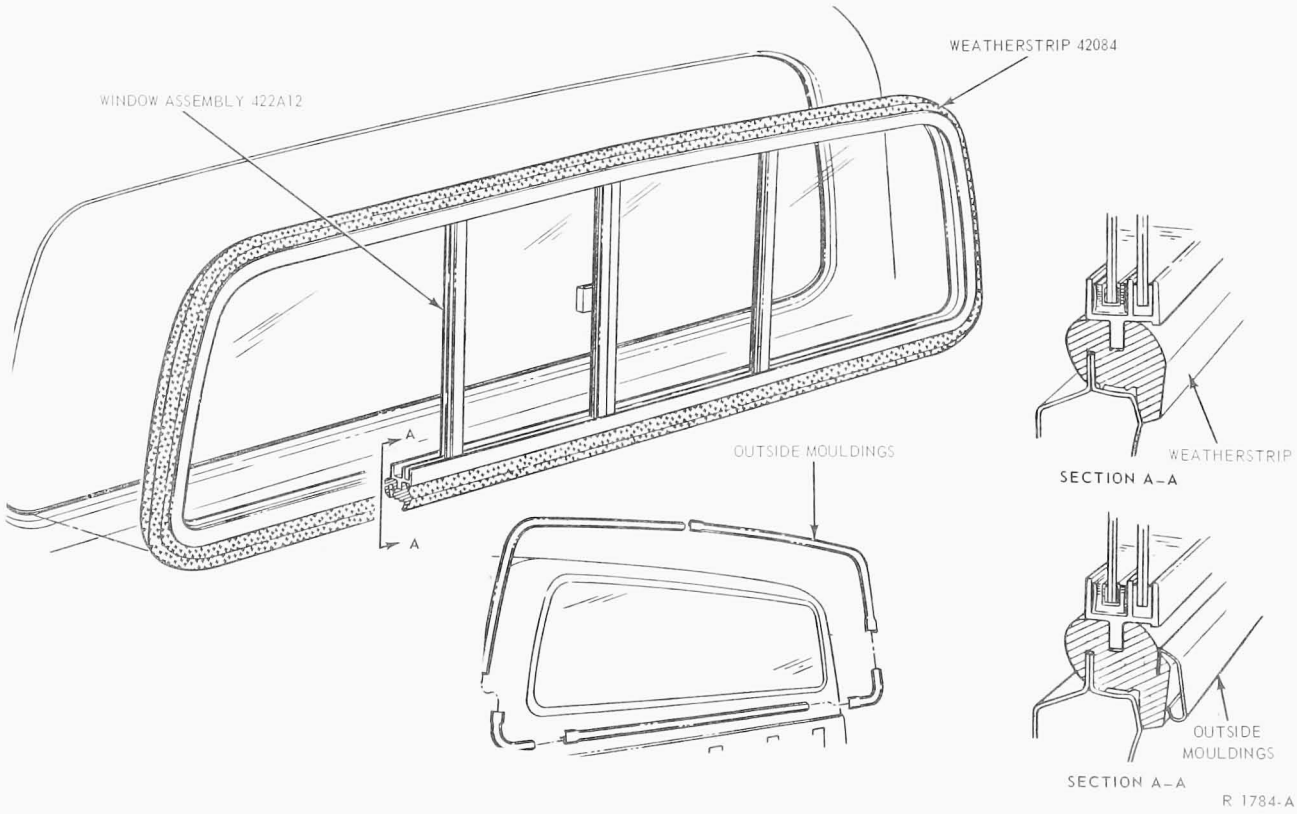

FIG. 12 Movable Back Window—F-100 through F-750, 6000 and 7000

apply hand pressure on the glass. From the inside, draw the lip of the weatherstrip over the window opening lower flange with a draw cord. Alternate from side to side, moving about 12 inches at a time, until the window is in place.

7. Water test the installation for leaks, and seal with additional caulk and sealer if necessary.

BODY SIDE AND REAR WINDOW GLASS

ECONOLINE

1. Loosen the weatherstrip around the inside and outside of the window opening.
2. From the inside of the vehicle, push the glass and weatherstrip from the window opening.
3. Remove the weatherstrip from the glass.
4. Clean the weatherstrip and body opening to remove all old sealer.
5. Apply sealer (C5AZ-19554-A) in the glass groove of the weatherstrip (Fig. 11).
6. Apply sealer (C5AZ-19554-A) around the entire perimeter of the window opening.
7. Position the weatherstrip to the window glass. Install a draw cord in the pinch weld opening of the weatherstrip. Overlap the cord about 18 inches at the lower center of the glass and tape the ends of the cord to the inside of the glass.
8. Position the window glass and weatherstrip to the body opening.
9. With an assistant applying hand pressure from the outside, pull the draw cord to pull the lip of the weatherstrip over the window opening flange. Draw the weatherstrip over the lower flange, each side flange, and then over the upper flange.
10. Clean the glass, weatherstrip, and surrounding area to remove all excess sealer.
11. Test for water leaks.

MOVABLE BACK WINDOW

F-100 THROUGH F-750, 6000 AND 7000

Removal

1. Remove the outside moulding from the weatherstrip, (if so equipped).
2. Push the back window and weatherstrip out of the window opening from inside the cab.
3. Remove the weatherstrip from the window and place the movable windows in the open position.
4. From the bottom of the window frame, remove the screw retaining each division bar. Also, remove the two screws retaining the anchor plate in the window track and remove the plate.
5. Spread the window frame and work the movable glass out of its track, and remove it from the frame.
6. If the stationary glass is to be replaced, remove the division bar top retaining screw and remove the division bar.
7. Spread the window frame just enough to permit the stationary glass to be worked out of the frame.

Installation

1. If the stationary glass is to be replaced, apply Lubricant (19558) to the window weatherstrip and track. Spread the frame slightly and slide the glass into place, in the frame. Do not allow the weatherstrip to bunch.
2. Position the division bar in the frame and install the top retaining screw.
3. Spread the frame slightly and install the movable glass in its track.
4. Position the anchor plate in the window track ad install the two retaining screws.
5. Install the division bar lower retaining screws.
6. Position the weatherstrip to the window frame.
7. Install a draw cord all around the weatherstrip in the flange crevice, allowing the cord to overlap at the bottom center of the glass.
8. Apply sealer to the back window opening as shown in Fig. 12.
9. Position the glass and weatherstrip to the window opening. With an assistant applying hand pressure from outside the cab, pull the weatherstrip lip over the window opening flange with a draw cord. Pull the weatherstrip over the lower flange, pulling one end of the cord at a time. Then, pull the seal over the side flanges and upper flange. Install the outside mouldings (if so equipped).

GENERAL INFORMATION

DOOR AND WEATHERSTRIP LUBRICANT

SILICON LUBRICANT COAZ-19553-A (JELLY) AND COAZ-19533-C (SPRAY)

This lubricant is to be used on the door and window weatherstrips. It is recommended that silicon lubricant be applied to the upper weatherstrips at every regular lubrication period. Its use makes the doors easier to close, avoids weatherstrip squeaks, retards excess weatherstrip wear from chafing between the door glass upper frame and the weatherstrip. Also, it helps to retain door window alignment by reducing friction between the glass frame and the rubber weatherstrip.

DOOR, HOOD AND TAILGATE HINGES—LUBRICANT

POLYETHYLENE GREASE C4AZ-19584-B

This lubricant is used to lubricate door hinges. Apply an even coat to all movable hinge surfaces when a binding condition occurs (Fig. 1).

LOCK CYLINDER LUBRICANT

LOCK LUBRICANT B4A-19587-A

This lubricant is used to eliminate sticking or binding of all key lock cylinders.

ADJUSTMENTS

DOOR ALIGNMENT

BRONCO AND C-SERIES

The door hinges provide sufficient adjustment to correct most misalignment conditions. The elongated holes where the hinges attach to the pillars provide in and out movement of the door to obtain flush fits with the cowl side panel (Fig. 1). On Bronco models, fore and aft movement of the door can be achieved by the insertion or removal of shims between the door hinges and the door pillar. **Do not try to correct door misalignment by adjusting the striker.**

The bolt holes where the doors attach to the hinges are enlarged (Fig. 1). This permits a circular movement of the door to obtain proper spacing all around it.

1. Determine which hinge bolts must be loosened to move the door in the desired direction.
2. Loosen the hinge bolts enough to permit movement of the door with a padded pry bar.

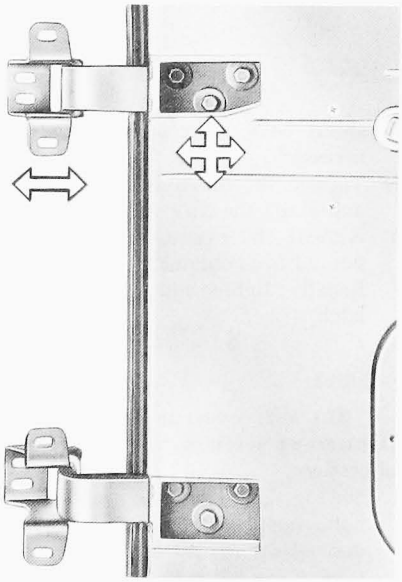

FIG. 1 Door Hinge Adjustment—Typical Except W and F-Series

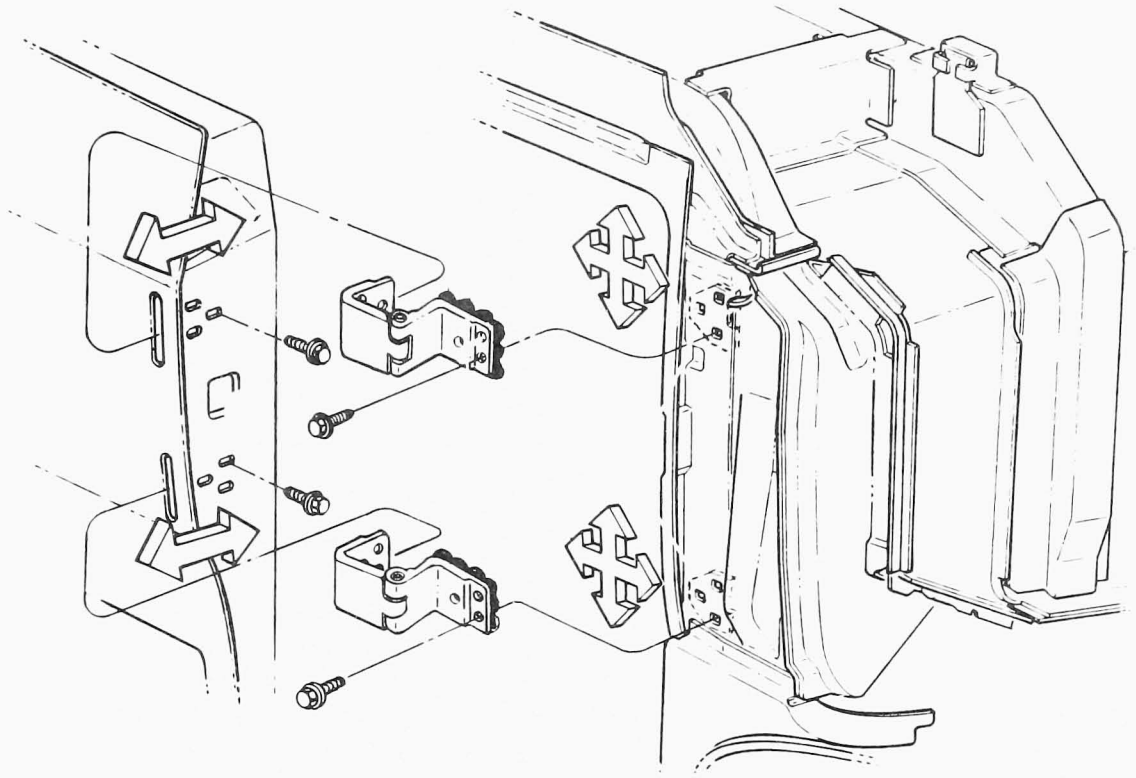
3. Move the door the distance estimated to be necessary.
4. Tighten the hinge bolts, and check the door fit.
5. Repeat the operation until the desired fit is obtained.

L-SERIES

The door hinge attachments to the door and pillar provide a means for adjusting the door position in the door opening. Elongated bolt holes in the door provide the in-out adjustment. Enlarged square bolt holes in the door pillar (Fig. 2) provide circular adjustment of the door. This adjustment gives the proper up-down and fore-aft position. To reach the door pillar bolts, it is necessary to remove the cowl side panel and hood latch from the cab.

ECONOLINE

The door hinge attachment to the door and body pillar provides a means for adjusting the door in the body opening. This is accomplished by enlarged hinge bolt holes in the door and pillar. A floating hinge reinforcement plate, threaded to accept the hinge bolts,



N1898-A

FIG. 2 Door Hinge—L-Series

is used to attach the upper hinge to the pillar (Fig. 3). The lower hinge is attached to the pillar by threaded holes in the hinge. The hinges are attached to the door in the same way.

The upper hinge can be adjusted up or down and in or out by loosening the hinge attaching screws and moving the hinge. Fore and aft movement of the hinge is accomplished by adding or removing shims between the hinge and the pillar (Fig. 3).

The lower hinge can be adjusted up or down and fore or aft by loosening the hinge-to-pillar attaching screws and moving the hinge. In or out movement of the lower hinge is provided at the hinge-to-door attachment.

1. Loosen or remove the door latch striker to prevent interference during door alignment.
2. Loosen the hinge attaching bolts enough to permit movement of the door with a padded pry bar.
3. Move the door the distance estimated to be necessary to obtain a proper fit.
4. If it is necessary to move the door forward or rearward, add or remove shims behind the upper hinge as necessary.
5. Tighten the hinge attaching bolts, and check the door fit.
6. Repeat the operation until the desired fit is obtained.
7. Install or tighten and adjust the door latch striker.

F-SERIES

Do not cover up a poor door alignment with a latch striker adjustment.

1. See Fig. 4, to determine which hinge bolts must be loosened to move the door in the desired direction.
2. Loosen the hinge bolts just enough to permit movement of the door with a padded pry bar.
3. Move the door the distance estimated to be necessary. Tighten the hinge bolts and check the door fit, to be sure there is no bind or interference with the adjacent panel.
4. Repeat the operation until the desired fit is obtained, and check the striker plate alignment for proper door closing.
5. Repeat the operation until the desired fit is obtained.

HINGED—CARGO DOOR ALIGNMENT

ECONOLINE

The door hinge attachment to the door and body provide a means for adjusting the doors in the body opening. Up or down and in or out adjustment is accomplished by enlarged holes at the hinge-to-door attachment (Fig. 5). Side to side movement of the doors is provided by adding or removing shims between the hinge and the body except on the front side cargo door. **The hinges of the front side cargo door should not be shimmed.**

The cargo doors should be adjusted to obtain a proper fit. After the doors have been adjusted, tighten the hinge attaching bolts securely, and adjust the latch mechanisms if required.

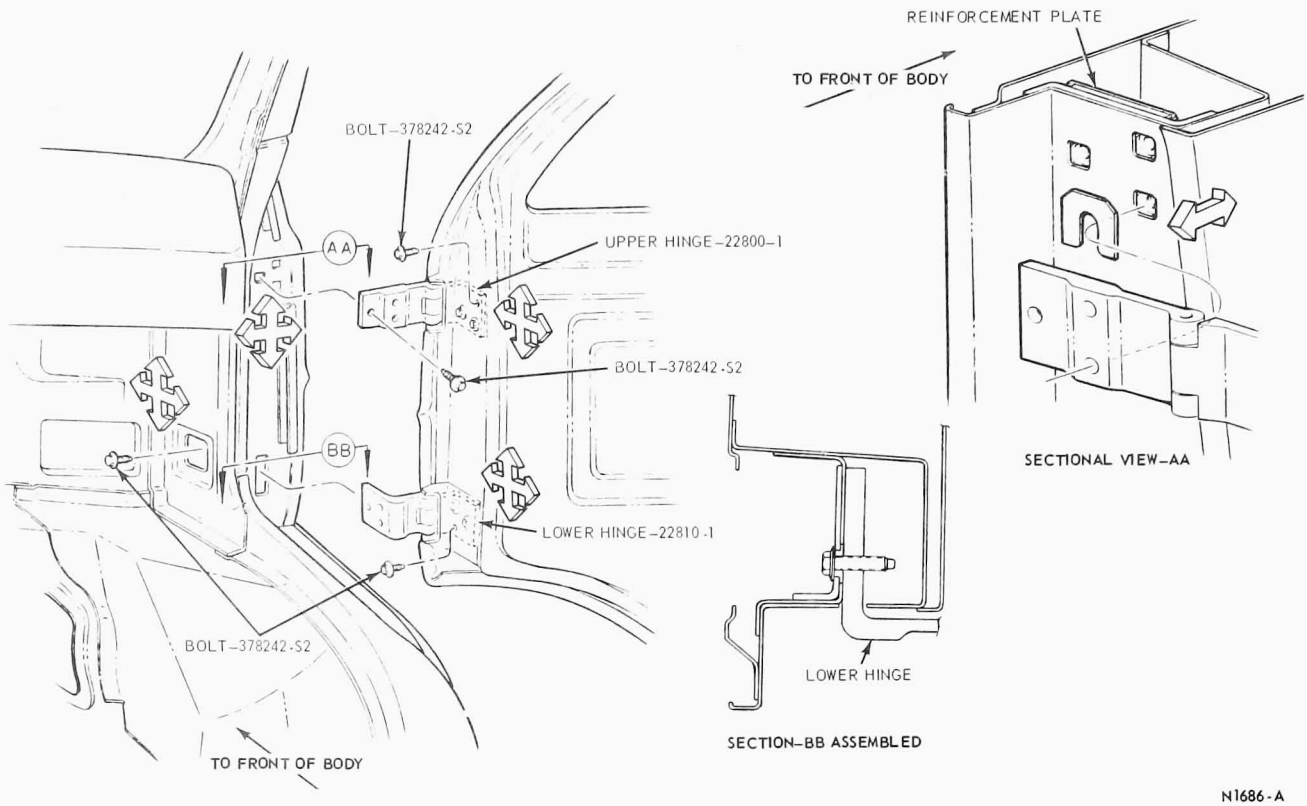


FIG. 3 Front Door Adjustment—Econoline

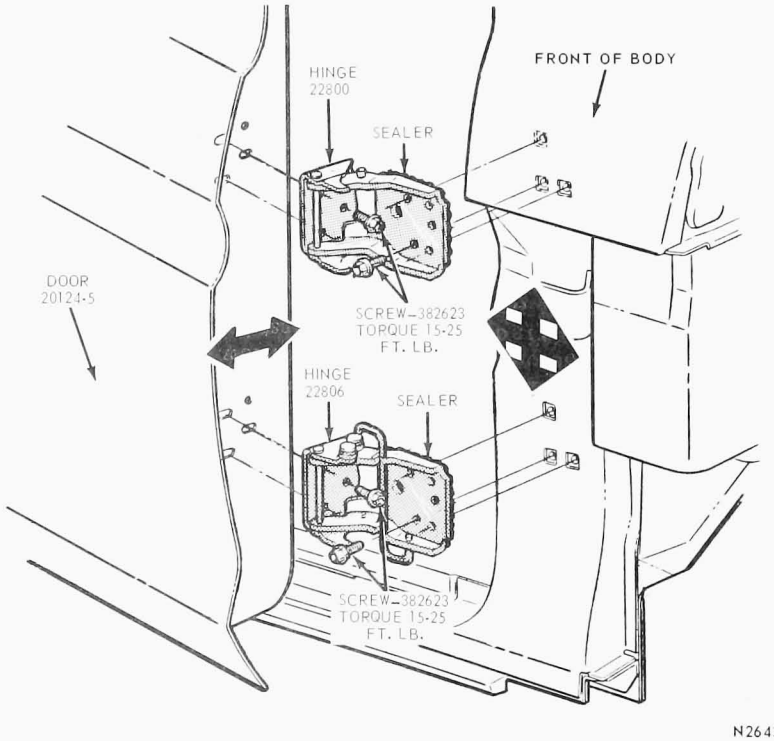

FIG. 4 Door Hinge Adjustment—F-Series

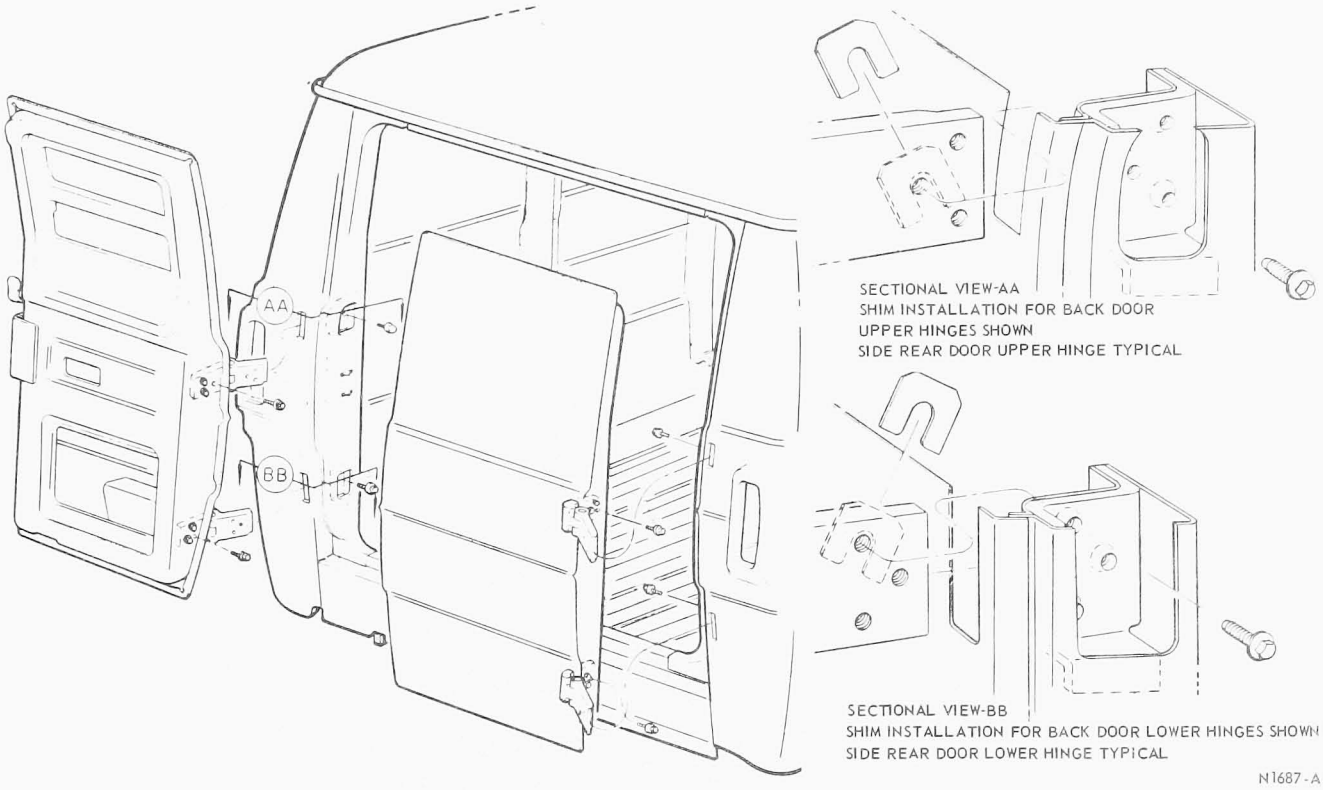

FIG. 5 Cargo and Back Door Alignment—Econoline

REMOVAL AND INSTALLATION

DOORS

Except W-Series

1. Remove all usable hardware, trim, and glass parts.
2. Remove the upper and lower hinge access hole cover plates (if so equipped).
3. Remove the door to lower hinge retaining bolts.
4. Support the door, and remove the door to upper hinge retaining bolts. Slide the door off the hinges.
5. If a hinge is to be replaced, remove the hinge to pillar bolts, and remove the hinge.
6. Cement the door weatherstrip in proper position on the door. Include the belt seals.
7. If a hinge has been removed, install the hinge in the pillar in approximately the same position as the removed hinge.
8. Position the door on the hinges, and install the retaining bolts snug.
9. Install the lock mechanism. Install the glass mechanism, glass, and vent window assembly. Make all necessary adjustments as these assemblies are installed.
10. Adjust the door, and tighten all hinge bolts securely. To provide a good weatherstrip seal, the upper front edge of the door must be 3/16 inch inboard of the upper part of the pillar from the belt line to a point near the top of the door. Adjust the striker plate.
11. If the truck is so equipped, install the water shield. The top edge should be cemented to the inside surface of the inner panel.
12. Install the hinge access hole cover plates and the door access hole cover plate.

DOOR HINGE

Bronco, and L-Series

1. Open the door and remove the trim panel from the door.
2. Remove the attaching bolts from the upper and lower hinges and remove the door from the vehicle.
3. Remove three bolts attaching the hinge to the body pillar and remove the hinge.
4. Position the new hinge to the body and install the three attaching bolts snug but do not tighten.
5. Position the door to the hinges and install the three attaching bolts in each hinge. Do not tighten the hinge attaching bolts at this time.
6. Position the door in the body opening and tighten the hinge attaching bolts. Then, adjust the door latch striker.

DOOR HINGE

F-Series

1. Support the door.
2. Mark the location of the hinge on the door and body.
3. Remove the hinge-to-body attaching bolts.
4. Remove the hinge-to-door attaching bolts and remove the hinge.
5. Position the hinge to the door and body, and install the attaching bolts.

6. Adjust the door and hinges and remove the support.

DOOR AND/OR HINGE

W-SERIES

Removal

1. Mark the location of the hinge on the pillar post.
2. Support the door and remove seven screws attaching the check strap to the door.
3. Remove ten bolts and washers attaching the hinge to the pillar post and remove the door and hinge from the cab.
4. Remove the weatherstrip from the door frame.
5. Remove eleven bolts and washers attaching the hinge to the door frame and remove the hinge.

Installation

1. Position the hinge to the door and install the eleven attaching bolts and washers.
2. Apply rubber cement to the weatherstrip and door frame and position the weatherstrip in place.
3. Position the door and hinge to the body and install the attaching bolts and washers.
4. Adjust the door to fit the door opening and tighten the hinge attaching bolts.
5. Position the check strap to the door and tighten the attaching screws.

DOOR WEATHERSTRIPS

A typical door weatherstrip installation is shown in Fig. 6. Remove the weatherstrip, clean all old weatherstrip adhesive and apply new adhesive (Part Number 19552) to the retaining flanges. Then, install the weatherstrip.

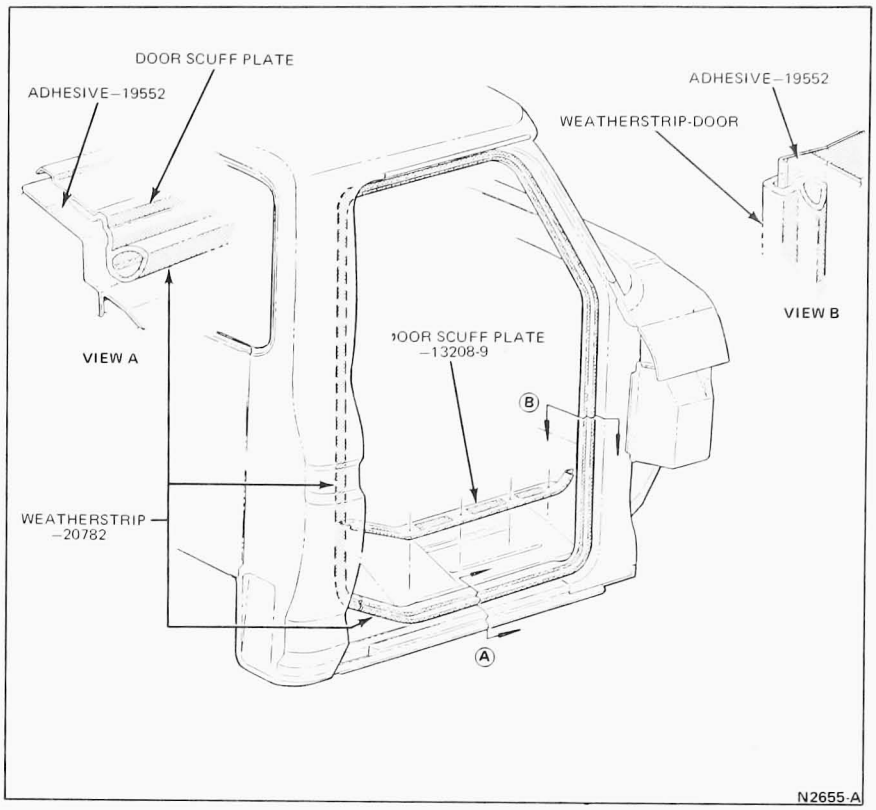

FIG. 6. Typical Door Weatherstrip Installation

PART 44-08 Sliding Door

Applies To Econoline Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS		DESCRIPTION AND OPERATION	08-01
Fore and Aft – Door	08-03	REMOVAL AND INSTALLATION	
Center Hinge Check	08-03	Hinge	08-06
Front Striker	08-03	Latch	
Latches	08-03	Front	08-05
Lower Check	08-03	Rear	08-06
Hinge Assembly	08-01	Lower Guide Assembly	08-05
In or Out – Door	08-01	Striker Plate	08-06
Striker – Rear Latch	08-03	Upper Bracket and Roller Assembly	08-05
Up or Down – Door	08-01	Weatherstrip	08-06

DESCRIPTION AND OPERATION

SLIDING DOOR

The door is operated by rotating the inside or outside handle (inside-rearward or outside-downward) to release the latch and sliding the door rearward to the full open position. When the door has been pushed fully rearward, the hold-open check will activate and thereby prevent the door from inadvertently closing. There are no intermediate hold-open positions. To close the door, the inside or outside handle must be activated (inside-forward or outside-upward) to release the door from the check position.

From the inside of the vehicle, the door can be locked by pushing down on the lock knob and cannot be opened unless the lock knob is in the up position. Locking or unlocking the door from the outside can be accomplished with the key only. Since the floor pan sheet metal design incorporates an integral side step in vehicles equipped with the sliding door, no movable auxiliary side step is required.

ADJUSTMENTS

SLIDING DOOR—IN OR OUT

UPPER ROLLER ASSEMBLY

To adjust the upper edge of the door, loosen the upper roller retaining nut and move the roller **in or out,** to obtain a flush fit with the body sheet metal at the top edge of the door (Figs. 1 and 2).

LOWER-GUIDE ASSEMBLY

Support the door assembly so that **no up or down** movement can be made to the door when performing the **in or out** adjustment.

To adjust the lower front edge of the door, loosen the retaining screws on the guide assembly and move the guide assembly **forward,** to obtain a snug fit to the body and **rearward** to move it away from the body, at the B pillar post (Fig. 1).

SLIDING DOOR—UP OR DOWN

UPPER ROLLER AND LOWER GUIDE ASSEMBLY

To move the front edge of the door up or down, loosen the three lower guide attaching screws (Fig. 3), then rotate the guide at the lower attaching screw to obtain the desired door **up or down** position.

If further adjustment is required to obtain the desired fit, loosen the upper roller bracket assembly attaching screws and adjust the bracket so that the bottom edge of the roller assembly is approximately 1/16 inch from the bottom flange of the upper track.

HINGE ASSEMBLY

To move the rear edge of the door **up or down,** remove the door trim panel and/or plug buttons (if so equipped) (Fig. 7). With the door in the open position, loosen the hinge assembly attaching screws (Fig. 1) and move the

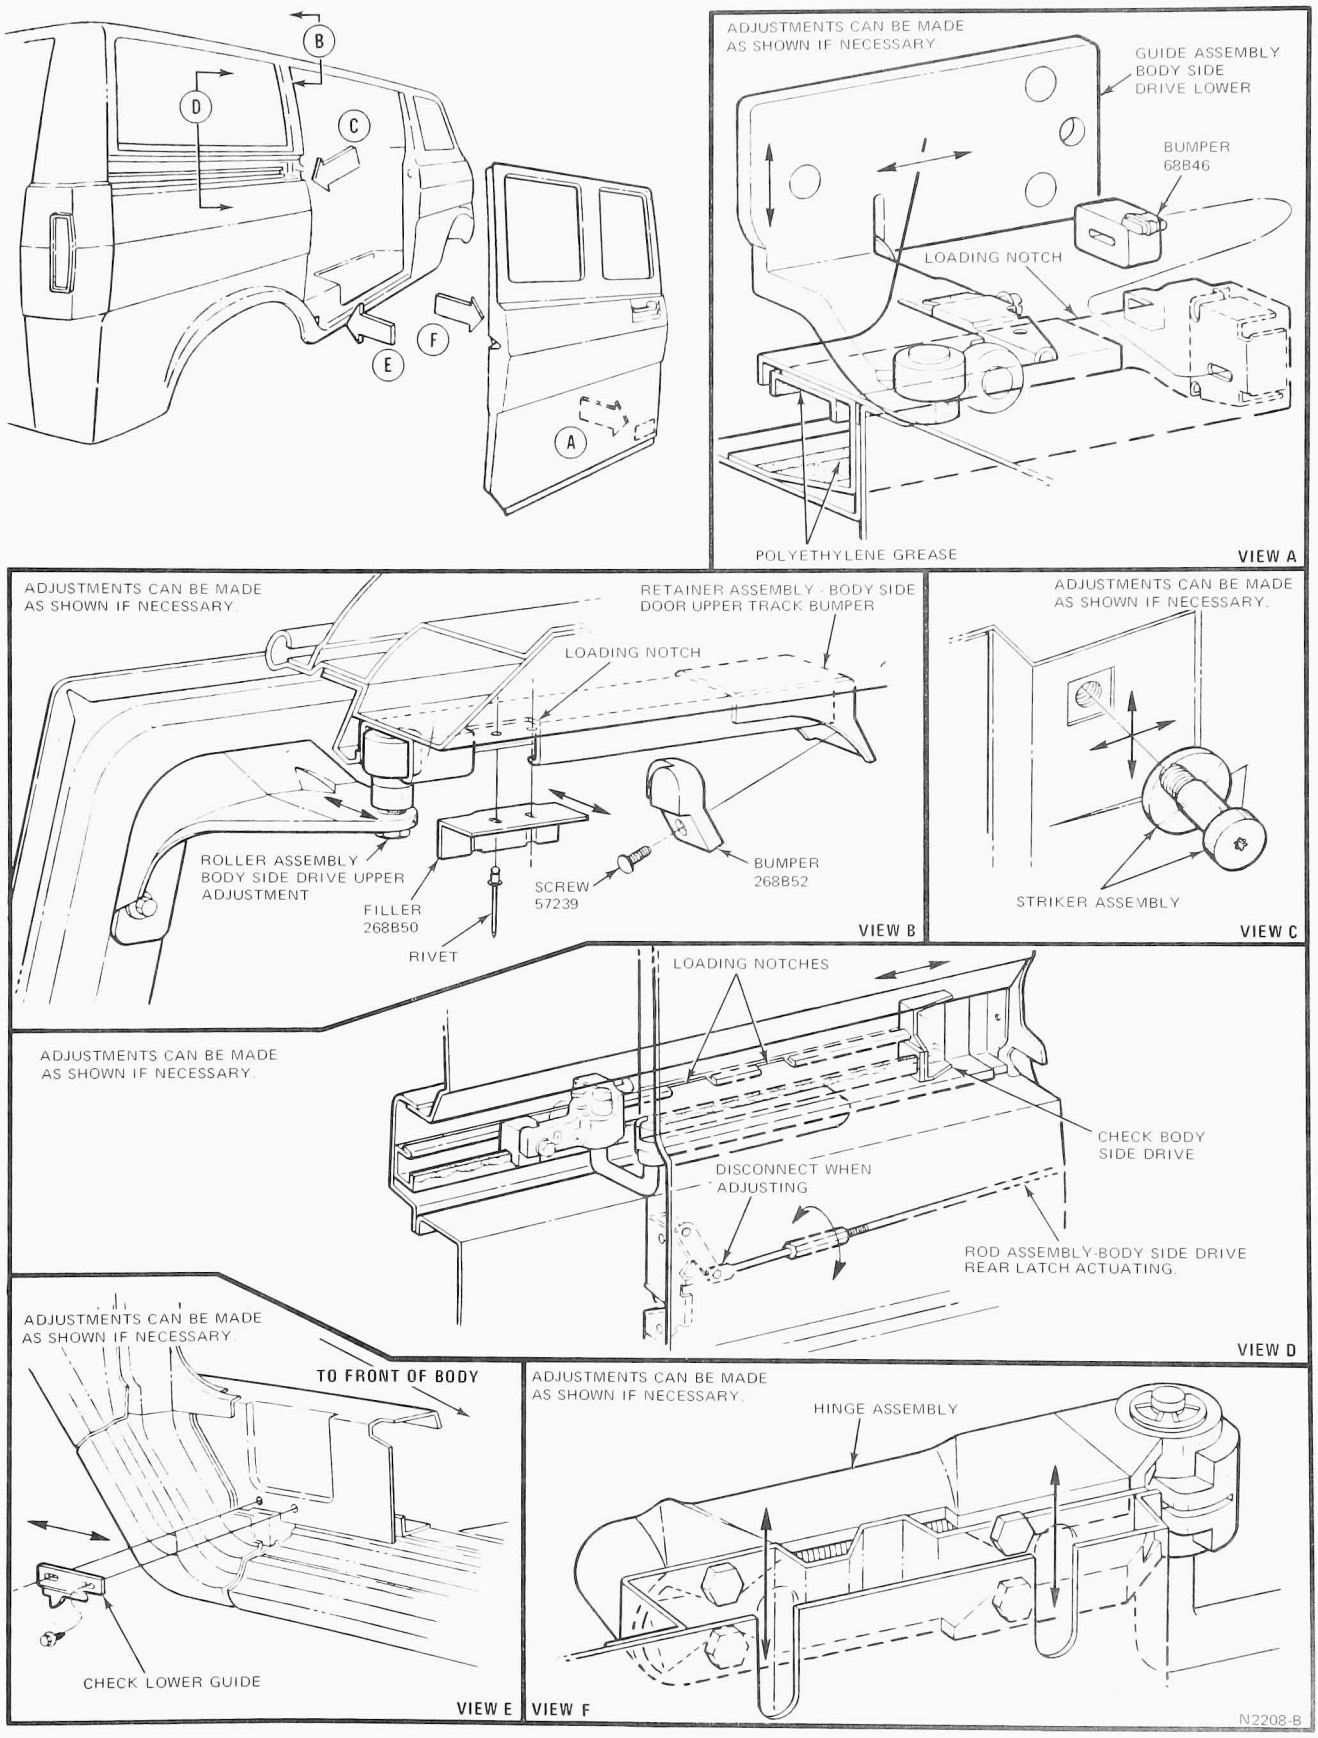

FIG. 1 Sliding Door Adjustments—Econoline

hinge assembly **up or down** to obtain the desired door position.

STRIKER—REAR LATCH

The rear latch striker assembly can be adjusted **up or down** and **in or out** . Loosen and adjust the striker, to obtain proper adjustment with the rear latch assembly (Fig. 1).

SLIDING DOOR—FORE AND AFT

CENTER HINGE CHECK AND FRONT STRIKER

To gain access to the hinge check, remove the interior stationary quarter glass garnish moulding. See Part 45-11 for garnish moulding removal. This will expose the nuts retaining the center track shield (five nuts short wheelbase vehicle) and (six nuts long wheelbase vehicle). Remove the nuts from inside the vehicle and the remaining two screws holding the center track shield from outside the vehicle. Then, remove the center track shield (Figs. 1 and 2).

Loosen the three bolts at the hinge check. **These bolts must be kept loose when making the fore and aft adjustment.** Then remove the B pillar post trim panel (nine screws). Loosen the (two) striker bolts and remove the striker (Fig. 2). Then, fit the door to the opening and adjust the door check (Fig. 2), so that it is fully engaged with the upper hinge lever and the check bumper is firmly depressed with the hinge casting.

Install the front striker assembly and add or remove shims to obtain the proper operation of the front latch assembly.

LOWER CHECK

The lower check holds the sliding door assembly in the full open position (Fig. 2). Loosen the two screws and push the door so that the lower guide roller is firmly against the overslam bumper. Adjust the check so that it is engaged with the edge of the hold-open stop and tighten the attaching screws.

SLIDING DOOR—LATCHES

Remove the sliding door trim panel. For trim panel removal, see Group 45.

The front and rear latch assembly adjustments are made with the rear latch actuating rod assembly (Figs. 5 and 6). Set the front latch in the latched position (one click of the latch mechanism) and the rear latch to the secondary position (one click of the latch mechanism). Then, disconnect the retainer at the rear latch assembly (Fig. 6) and adjust the sleeve and actuating rod to match the pivot arm on the latch. Connect the retainer to the rear latch assembly and check the door for proper latching.

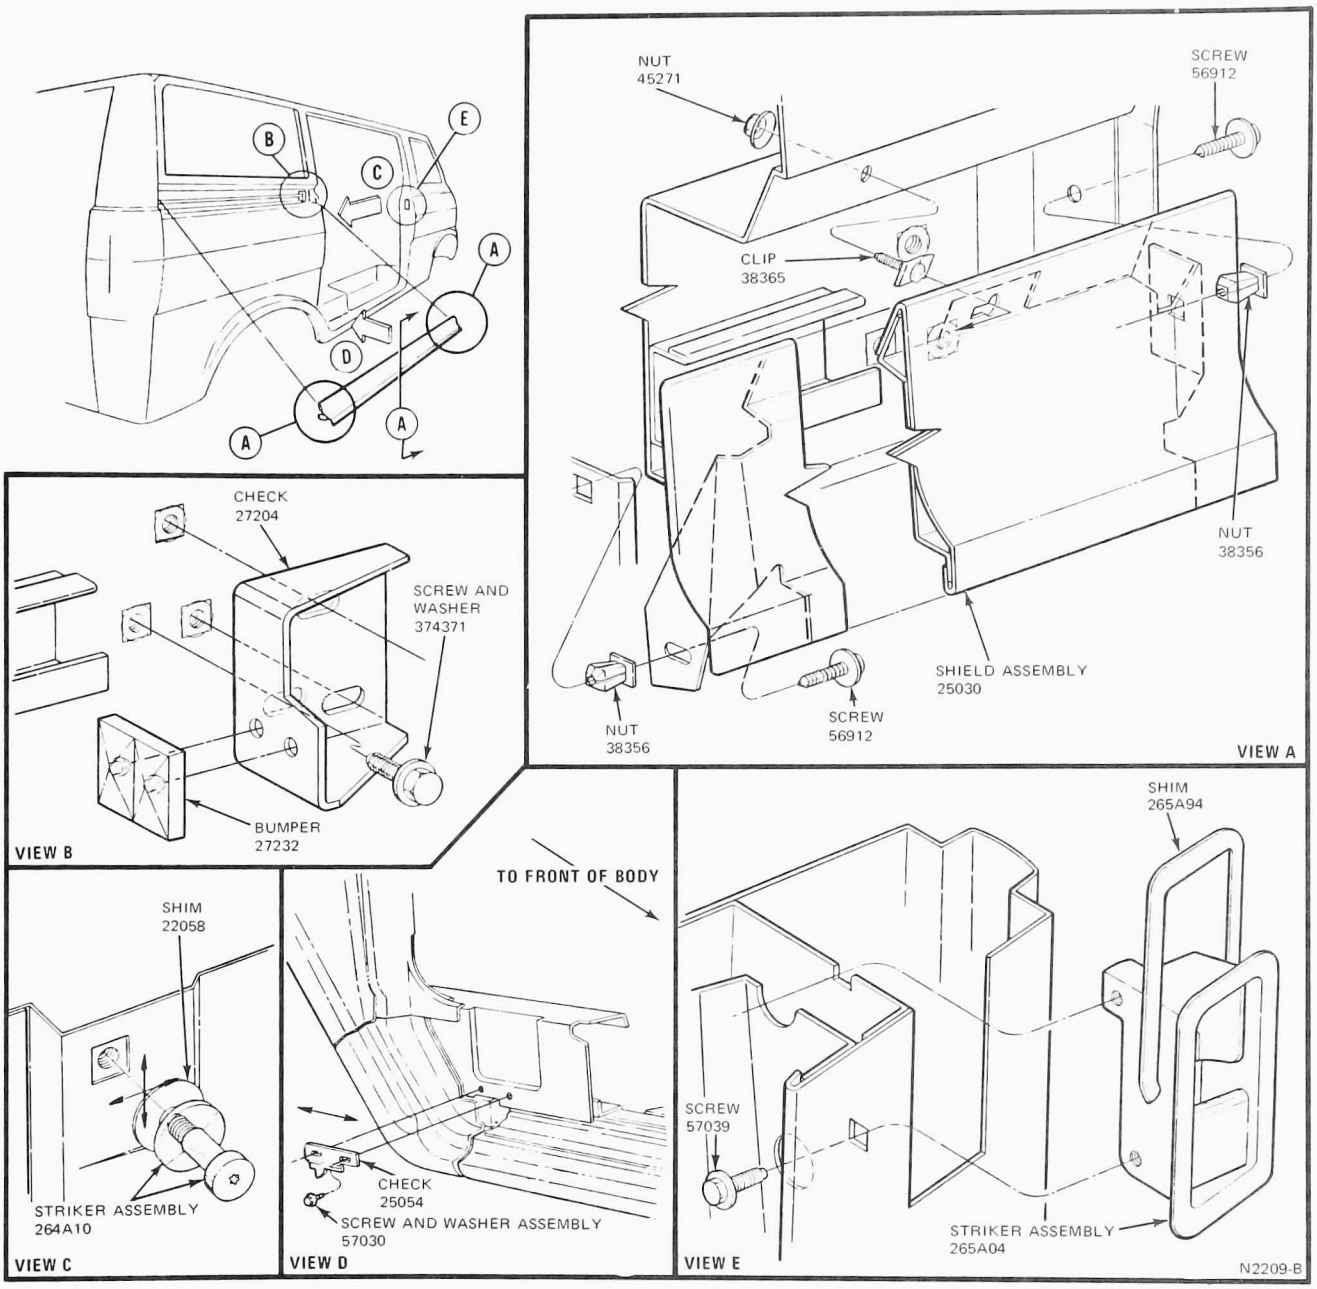

FIG. 2 Sliding Door Adjustments—Econoline

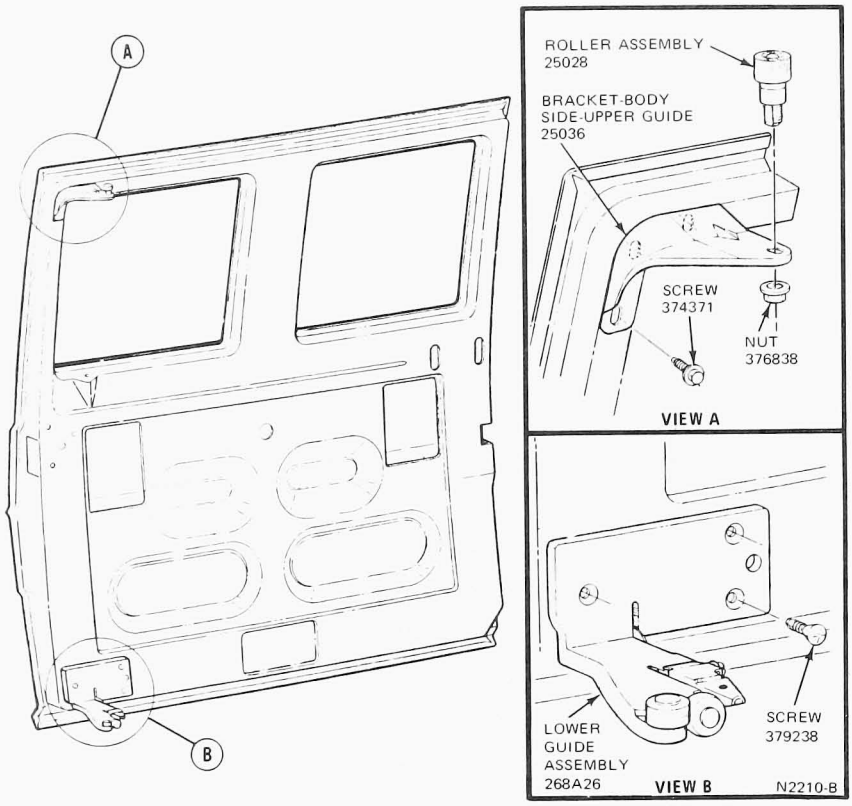

FIG. 3 Sliding Door—Guides and Rollers— Econoline

REMOVAL AND INSTALLATION

UPPER BRACKET AND ROLLER ASSEMBLY

1. Remove the upper garnish moulding, open and support the door.
2. Mark the location of the upper bracket assembly to the door (Fig. 3).
3. Remove the screws retaining the bracket and roller assembly and remove the assembly from the door, through the opening at the front of the upper track (Fig. 1).
4. If a new bracket is being installed, transfer the roller assembly to the new bracket.
5. Position the bracket and roller assembly to the door and install the three retaining screws (Figs. 1 and 3).
6. See Adjustment procedures outlined in this Section.

LOWER GUIDE ASSEMBLY

1. Open and support the door.
2. Remove the lower guide check screws and remove the check.
3. Slide the door forward on the support, to gain access to the lower guide attaching screws.
4. Mark the location of the lower guide bracket to the door (Fig. 1). and remove the guide attaching screws. **To gain access to the stop actuating rod retainer assembly (Figs. 3 and 5), rotate the guide assembly 90 degrees.** Then, disconnect the stop actuating rod from the stop and remove the guide assembly.
5. Connect the rod to the new lower guide stop arm and secure the retainer.
6. Position the guide assembly to the door and install the retaining screws.
7. Rotate the inside door handle forward to insure proper releasing action of the stop.
8. Install the lower guide check to the body and adjust the check as described under (Adjustments).

DOOR LATCH—FRONT

1. Note the position of the inside door handle before removing the trim panel (if so equipped).
2. **Do not remove the outside door handle screw.** Remove the outside door handle retainer and remove the handle and serrated shaft as an assembly (Fig. 4) from the door.
3. Remove the sleeve attaching screws and remove the sleeve (Fig. 4) from the latch.
4. Remove the rear latch actuating rod assembly from the rear latch (Fig. 6).
5. Remove the door lock rod from the lock cylinder and disengage it from the latch lever arm (Fig. 5).
6. Remove the stop actuating rod from the front latch.
7. Remove the three front latch retaining screws and disconnect the rear latch actuating rod from the latch.
8. Remove the front latch assembly through the access hole in the door.
9. Position the new latch assembly in the access hole opening and connect the rear latch actuating rod to the front latch.
10. Position the latch to the door and install the three retaining screws.
11. Connect the stop actuating rod to

the front latch.
12. Position the push button lock rod through the latch lever and connect the lock rod to the lock cylinder.
13. Position the sleeve to the latch assembly and install the retaining screws (Fig. 4).
14. Insert the outside handle assembly into the latch and install the handle retaining clip.
15. Connect the rear latch actuating rod to the rear latch assembly. **The front latch must be in the full latched position and the rear latch must be in the secondary position before connecting the rear latch actuating rod to the rear latch assembly.**
16. Check for proper latching operation before installing the door trim panel, escutcheon and inside door handle.

DOOR LATCH—REAR

1. Remove the door trim panel. (See Group 45).
2. Disconnect the actuating rod and retainer from the rear door latch arm (Fig. 6).
3. Remove the three latch retaining screws and remove the latch from the door.
4. Position the new latch assembly into the door and install the three retaining screws.
5. Connect the actuating rod and retainer to the door latch arm. **The front latch must be in the full latched position and the rear latch must be in the secondary position before connecting the actuating rod and retainer to the door latch arm.**
6. Check the latch operation and then, install the door trim panel. Refer to Adjustments if necessary.

DOOR HINGE ASSEMBLY

1. Open and support the door assembly.
2. Remove the center track shield as outlined in (Adjustments).
3. Remove the door trim panel and/or access hole covers (if so equipped).
4. Mark the position of the hinge assembly to the door and remove the four retaining screws from the hinge.
5. Slide the hinge assembly to a position in line with the loading notches located in the center track (Fig. 1) and remove the hinge assembly. A dissembled view is shown in Fig. 8.
6. Install the new hinge assembly through the loading notches in the center track and position the hinge to the door.
7. Install the hinge retaining screws and check the operation of the door.
8. Then, install the trim panel and/or access hole covers.
9. Install the center track shield.

WEATHERSTRIPS

1. Remove the weatherstrip from the door (Fig. 7).
2. Remove all the old weatherstrip adhesive
3. Apply adhesive to the cleaned area.
4. Install the weatherstrip (cut to length and butt the ends together).

STRIKER PLATE—FRONT DOOR

1. Remove the front roof rail moulding screws (Four) and position the moulding tip on the visor.
2. Remove the B pillar trim panel screws (nine).
3. Remove the striker bolts (two) and transfer the shim(s) to the new striker.
4. Position the striker and install the two attachiing bolts (snug) then, adjust as necessary.
5. Install the B pillar trim panel (nine screws).
6. Install the roof rail moulding and support assembly (four screws).

A page number indicates that the item for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

LATCH STRIKER ADJUSTMENT

Use tool No. T70P-2100-A where required.

The striker pin can be adjusted laterally and vertically as well as fore and aft. The latch striker should not be adjusted to correct door sag. The latch striker should be shimmed to get the clearance shown in Figs. 1 through 3, between the latch striker and the latch. To check this clearance, clean the latch jaws and the striker area, and then apply a thin layer of dark grease to the latch striker. As the door is closed and opened, a measurable pattern will result. Move the striker assembly laterally to provide a flush fit at the door and the body.

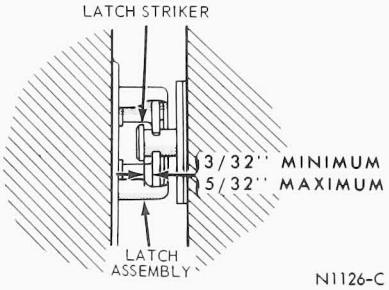

FIG. 3 Door Latch Striker Adjustment—Bronco

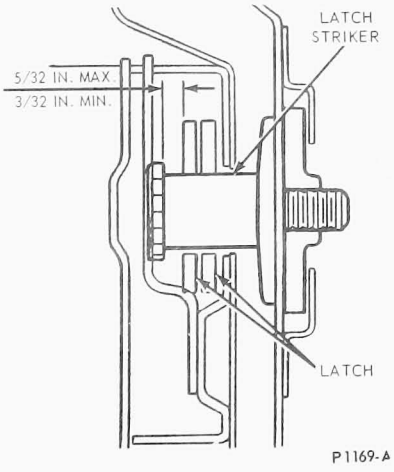

FIG. 1 Latch Striker Adjustment—Typical

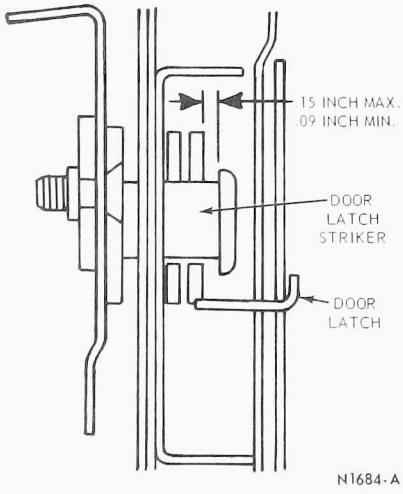

FIG. 2 Door Latch Striker Adjustment—Econoline

REMOVAL AND INSTALLATION

DOOR LATCH

L-W-AND C-SERIES

Removal

1. Remove the door trim panel and/or access hole cover attaching screws and remove the trim panel and/or the access hole cover.
2. Disconnect the remote control link and the push button rod (Figs. 5 through 9) from the latch assembly.
3. Remove three screws attaching the latch to the door and remove the latch assembly.

Installation

1. Lubricate the latch assembly with Polyethelyne grease (Part Number 19584).
2. Position the latch assembly to the door and install the three attaching screws.
3. Connect the push botton rod and the control link to the latch assembly.
4. Check the operation of the latch and install the trim panel and/or access hole cover.

F-100 THROUGH F-750

Removal

1. Remove the trim panel and watershield from the door.
2. Disconnect the rods from the latch assembly (Fig 4).
3. Remove the latch assembly attaching screws and remove the latch from the door.

Installation

1. Install the rod retaining clips in the new latch assembly.
2. Position the latch in the door and install the latch attaching screws.
3. Connect the rods to the latch assembly and check the operation of the latch.
4. Install the watershield and trim panel on the door.

FRONT DOOR LATCH

ECONOLINE

Removal

1. Remove the access cover from the door inner panel.
2. Disconnect the remote control link and the push button rod (Fig. 10) from the latch assembly.
3. Remove three screws attaching the latch to the door and remove the latch assembly.
4. Remove the link and rod retainers from the latch assembly.

Installation

1. Install the rod and link retainers on the latch assembly.
2. Lubricate the latch assembly with Polyethelyne grease (19584).
3. Position the latch to the door and install the three attaching screws.
4. Connect the push button rod and the remote control link to the latch assembly.
5. Check the operation of the latch and install the door inner panel.

DOOR LATCH

BRONCO

Removal

1. Raise the window all the way up.
2. Remove the door inside handles.

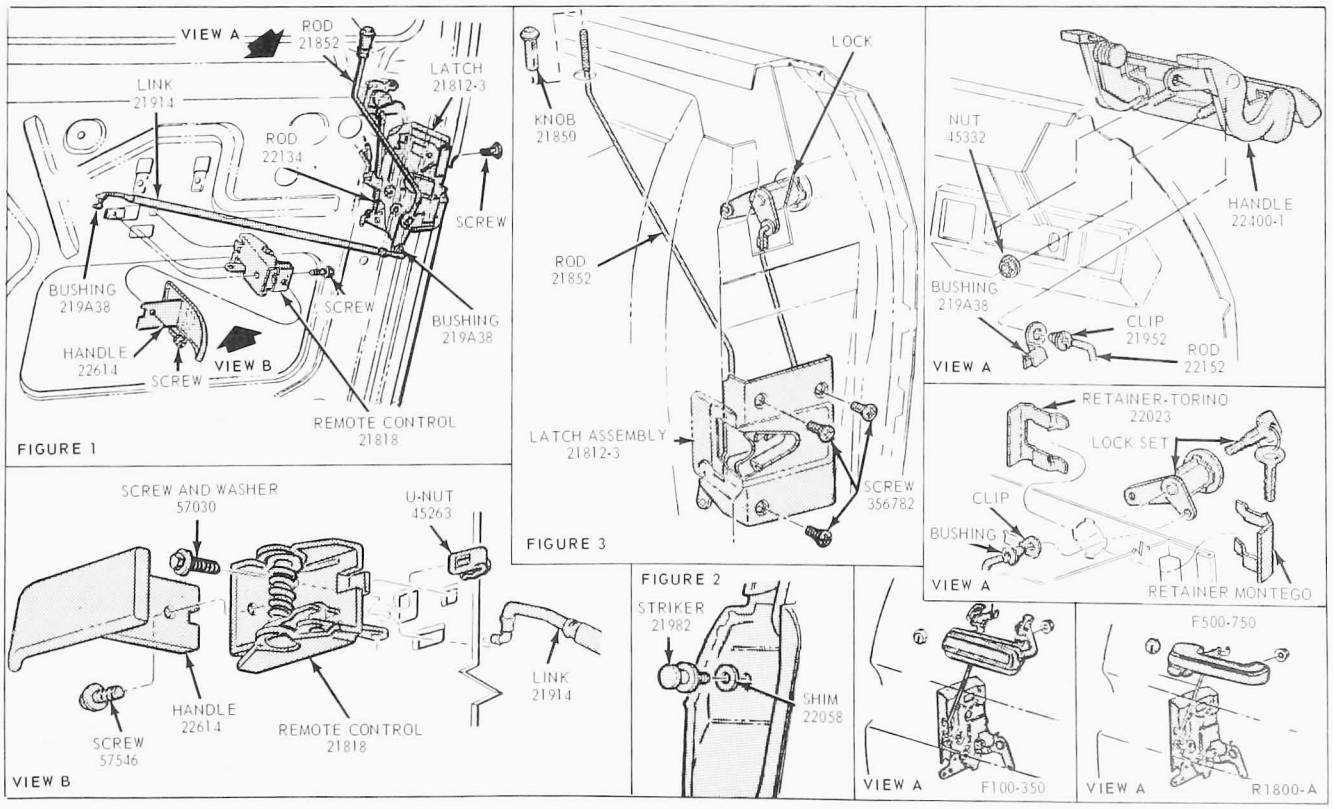

FIG. 4 Door Latch Installation—F-Series

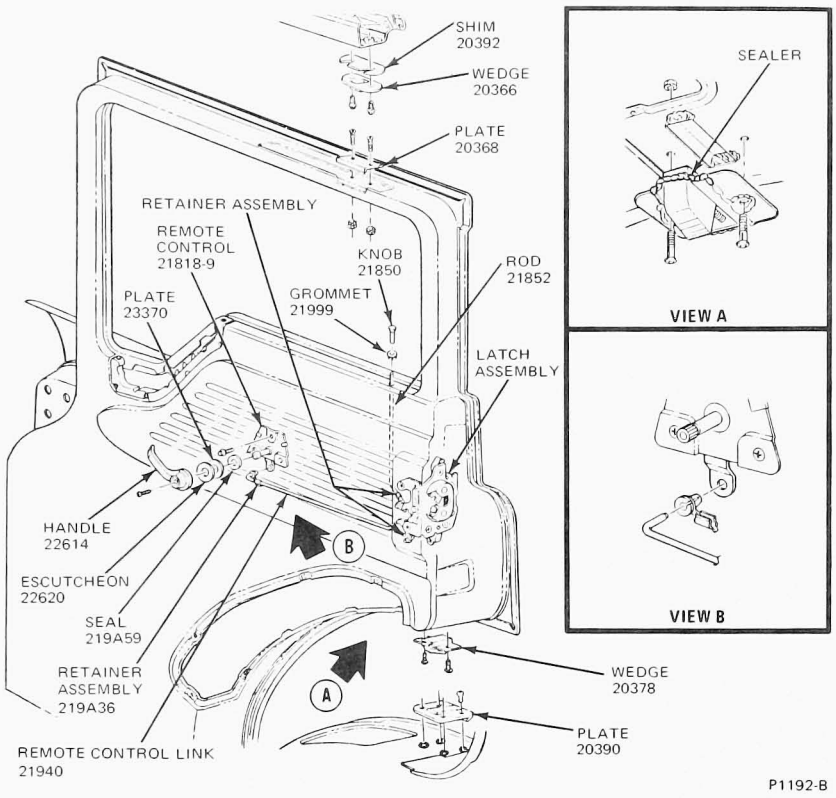

FIG. 5 Door Latch Installation—C-Series

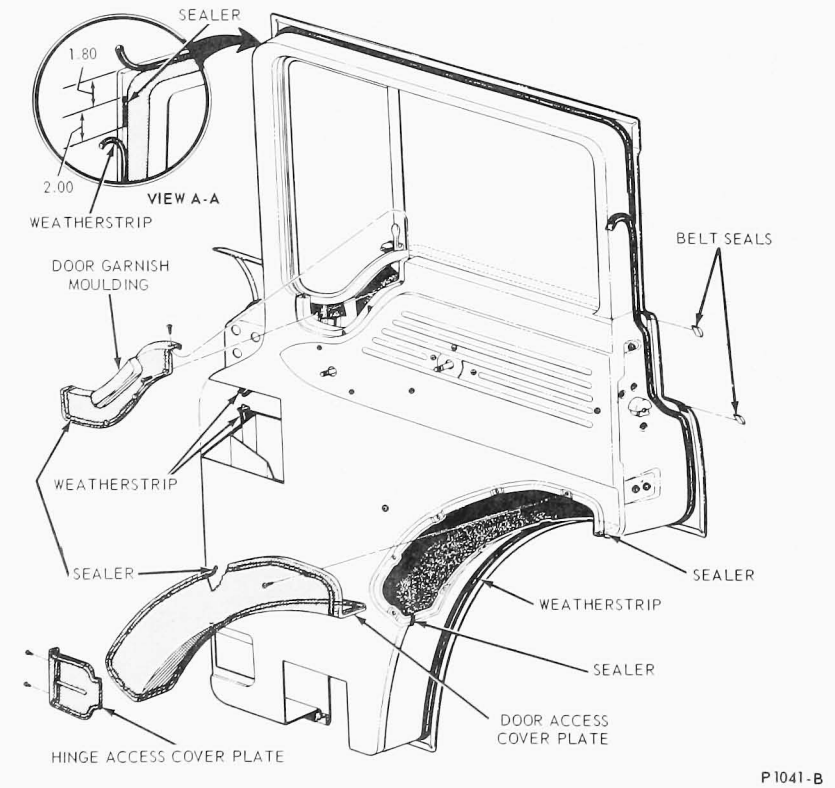

FIG. 6 Door Latch Access Hole Covers—C-Series

3. Remove the seven screws that secure the access cover plate to the door inside panel. Remove the access cover plate and the water shield.
4. Remove the two door glass rear run attaching screws and remove the rear run (Group 42).
5. Remove the retainers that secure the door latch control rod and the door latch actuating rod to the door latch assembly (Fig. 11). Disconnect the rods from the door latch assembly.
6. Remove the three screws that secure the door latch assembly to the door lock post. Remove the door latch from the door through the access hole opening.

Installation

1. Position the door latch assembly against the inner side of the door lock post.
2. Secure the door latch assembly to the door lock post with three screws.
3. Position the door latch control rod and the door latch actuating rod on the door latch assembly and secure the rods with the retainers.
4. Install the door glass rear run in the door.
5. Cement the water shield to the inside surface of the inner door panel.
6. Position the access cover plate and secure it with seven screws.
7. Install the door inside handles.

DOOR LATCH—CARGO FRONT SIDE OR RIGHT REAR DOOR

ECONOLINE

Removal

1. Remove the trim panel from the door, if so equipped.
2. Disconnect the lock cylinder rod from the door latch.
3. **SIDE DOOR ONLY: Disconnect the push button rod and the remote control link from the latch.**
4. Remove three screws attaching the latch to the door, and remove the latch from the door.
5. Transfer the rod retainers to the new latch.

Installation

1. Position the latch assembly in the door and install the three attaching screws.
2. **SIDE DOOR ONLY:** Connect the push button rod and the remote control link to the latch.
3. Connect the lock cylinder rod to the door latch.
4. Install the door trim panel, if so equipped.

DOOR LATCH AND/OR REMOTE CONTROL—CARGO REAR SIDE OR LEFT REAR DOOR

ECONOLINE

Removal

1. Remove the inside handle from the remote control shaft.
2. Disconnect the lower latch rod from the remote control (Fig. 12).
3. Remove three screws attaching the lower latch guide to the bottom of the door (Fig. 12). Remove the lower latch assembly from the door.
4. Remove three screws attaching the remote control to the door.
5. Remove three screws attaching the upper latch guide to the top of the door (Fig. 12). Remove the upper latch assembly and remote control from the door.
6. Disconnect the upper latch assembly from the remote control.

Installation

1. Assemble the upper latch assembly to the remote control (Fig. 12).
2. Position the upper latch assembly and remote control to the door. Install three screws attaching the upper latch guide to the top of the door.
3. Position the lower latch assembly in the door and connect the lower latch rod to the remote control.
4. Install three screws attaching the lower latch guide to the door.
5. Install three screws attaching the remote control to the door.
6. Install the inside handle on the remote control shaft.
7. Adjust the door for a snug fit against the weatherstrip. This is done by loosening the latch guide attaching screws and moving the latch assembly inboard or outboard as required. Then, tighten the latch guide attaching screws.

REMOTE CONTROL

F-100 THROUGH F-750

1. Remove the door trim panel and watershield.
2. Disconnect the latch remote control rod from the remote control (Fig. 4).
3. Remove the screw attaching the remote control to the door inner panel, and remove the remote control.
4. Transfer the rod clip to the new remote control, if the remote control is to be replaced.
5. Position the remote control to the door inner panel and connect the rod to the remote control.
6. Install the remote control attaching screw.
7. Check the remote control and latch operation.
8. Install the watershield and door trim panel.

ALL EXCEPT F-100 THROUGH F-750

1. Raise the window all the way up.
2. Remove the inside door handle.
3. Remove the access hole cover and/or trim panel and pull away the water shield.
4. Remove the remote control retaining screw(s) (Figs. 5 through 13).
5. Swing the remote control down to the access hole and disconnect the remote control rod from the remote control.
6. Insert the remote control assembly through the access hole and connect the remote control rod to the remote control assembly.
7. Position the remote control and install the retaining screw(s).
8. Install the water shield. The top edge should be cemented to the inner surface of the inner panel.
9. Install the access hole cover plate and/or trim panel.
10. Install the inside door handle.

LOCK CYLINDER

When a lock cylinder is replaced, both door lock cylinders and the ignition lock cylinder should be replaced in a set. This will avoid carrying an extra key which will fit only one lock. If a key is to be replaced, the new key code number is stamped on a metal tag attached to the key.

1. Roll the window to the up position.
2. Remove the access hole cover and/or trim panel and pull away the water shield.
3. Disconnect the lock actuating rod from the lock control link clip.
4. Slide the lock cylinder retainer away from the lock cylinder (Figs. 4 through 16).
5. Remove the lock cylinder.
6. Insert the lock cylinder in the door and connect the lock cylinder retainer.
7. Connect the lock actuating rod to the lock control link clip.
8. Install the water shield. Cement the top edge of the water shield to the top inner surface of the inner panel.
9. Install the access hole cover and/or trim panel.

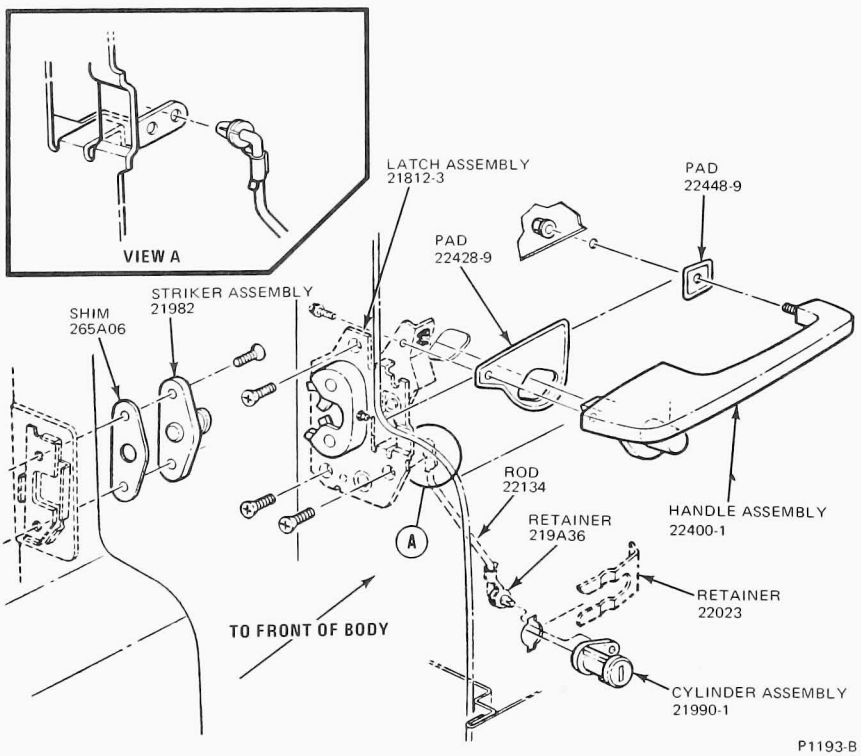

FIG. 7 Door Latch Mechanism—C-Series

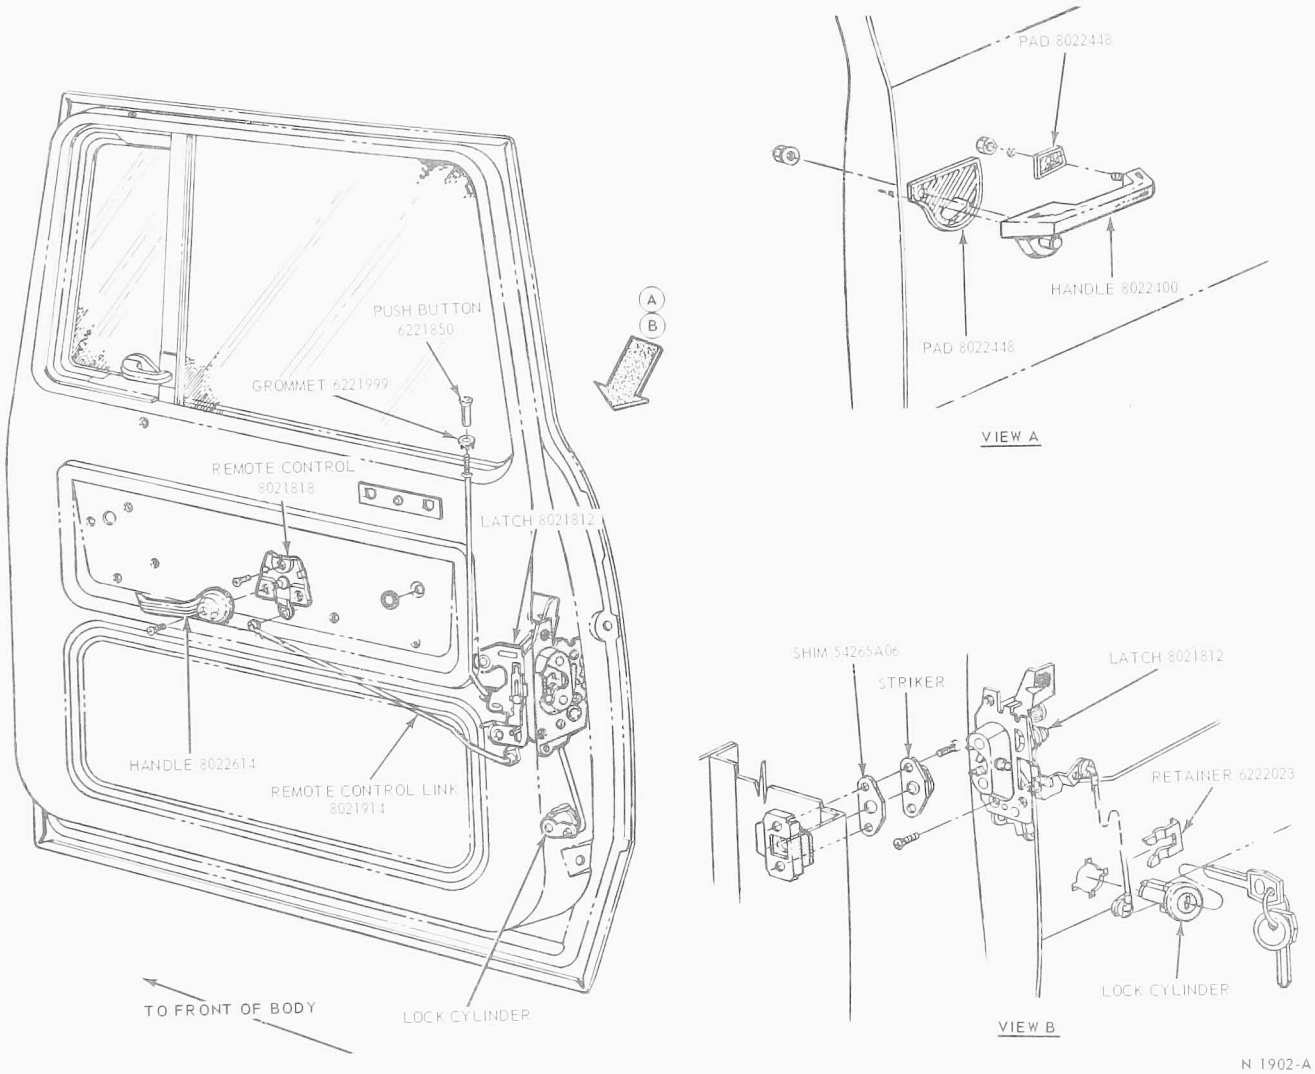

FIG. 8 Door Latch Mechanism—L-Series

DOOR INSIDE HANDLE—CARGO FRONT SIDE DOOR

ECONOLINE

Removal

1. Remove the trim panel from the door, if so equipped (Group 45).
2. Disconnect the rod at the door inside handle bellcrank.
3. Remove three screws attaching the inside handle bracket to the door inner panel and remove the handle.
4. Remove the mounting bracket from the inside handle.

Installation

1. Install the mounting bracket on the inside handle.
2. Position the handle and bracket assembly to the door inner panel and install the three attaching screws.
3. Connect the rod to the inside handle bellcrank.
4. Install the trim panel on the door, if so equipped.

DOOR INSIDE HANDLE

ALL EXCEPT F-100 THROUGH F-750

Removal

To remove the window regulator handle and/or the inside door handle, remove the set screw(s) that secure the handle(s) to the serrated shaft(s) protruding from the inside door panel.

Installation

1. With the window in the down position, install the window regulator handle on the serrated shaft of the regulator assembly so that the handle points in a forward direction with the center line of the handle approximately 75 degrees above the horizontal line of the body. Install the set screw to secure the handle to the serrated shaft.
2. Install the door handle on the serrated shaft of the remote control assembly so that the handle points in a foward direction with the center line of the handle approximately 75 degrees above the horizontal line of the body. Install the set screw to secure the handle to the serrated shaft.

F-100 THROUGH F-750

To remove the door inside handle,

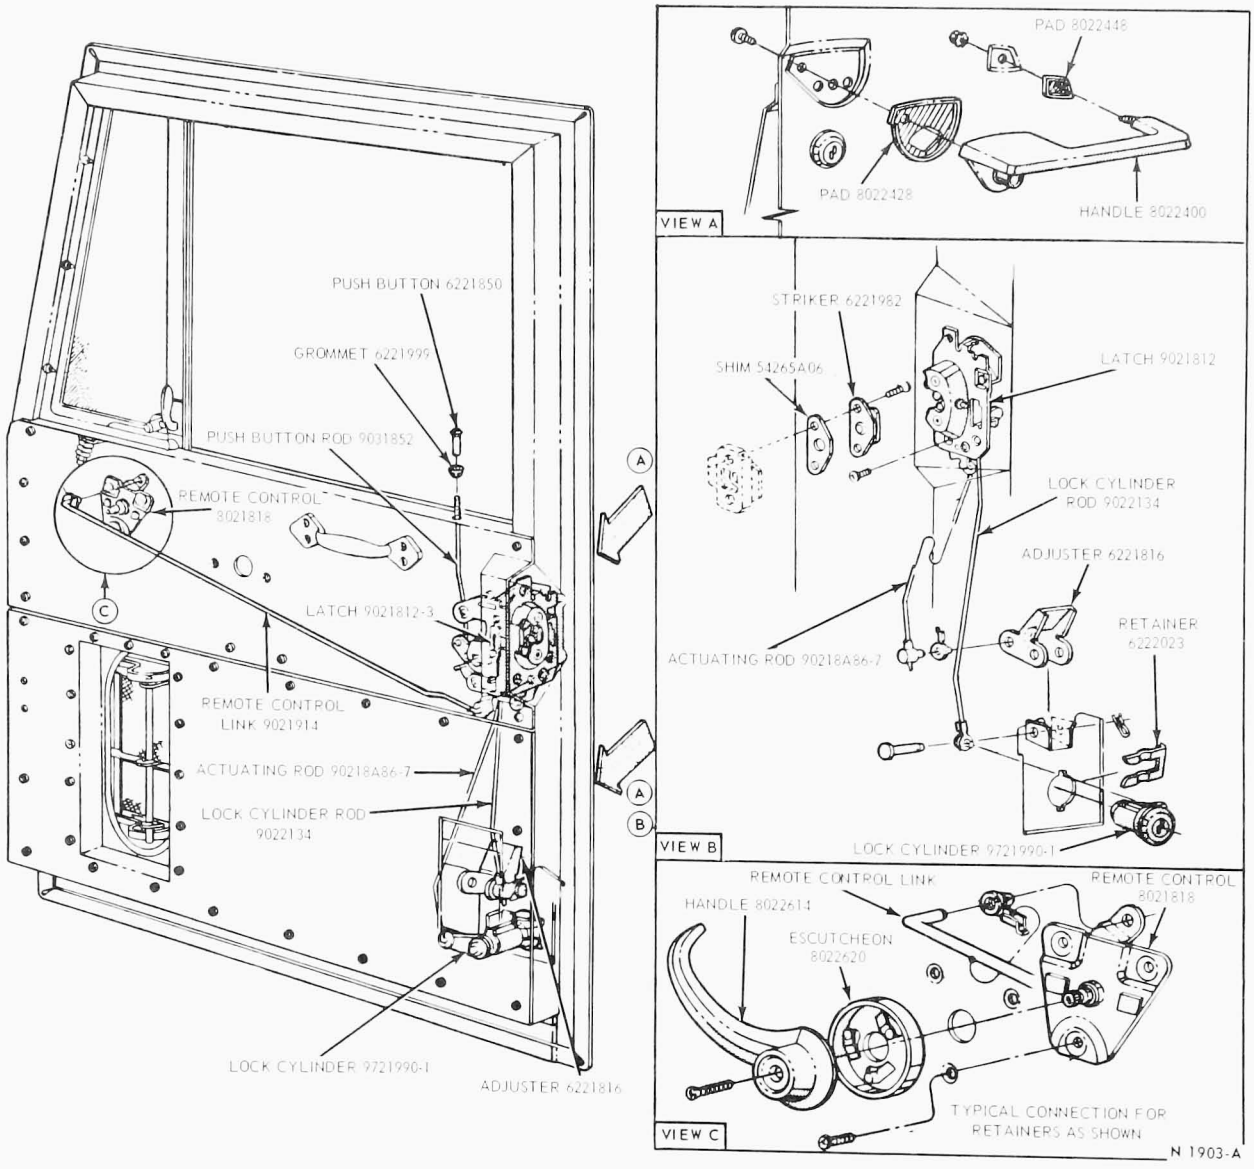

FIG. 9 Door Latch Mechanism—W-Series

remove one screw and remove the handle (Fig. 4).

DOOR OUTSIDE HANDLE

W-SERIES

1. Remove the door check strap and the lower inner panel from the door.
2. Remove two screws and nuts attaching the outside handle to the door and remove the handle and pad.
3. Remove the lock cylinder from the outside handle and install the cylinder in a new handle if the handle is to be replaced.
4. Position the handle and pad to the door and the door latch remote control.
5. Install the two outside handle attaching screws and nuts.
6. Position the lower inner panel and check strap to the door and install the attaching screws.

F-100 THROUGH F-750

1. Remove the door trim panel and watershield (Group 45).
2. Disconnect the door latch actuator rod from the door outside handle (Fig. 4).
3. Remove two nuts retaining the handle to the door. Remove the handle and pad from the door.
4. Transfer the actuator rod clip and the pad to the new handle, if the handle is to be replaced.
5. Insert the handle into the door and install the two retaining nuts.
6. Connect the door latch actuator rod to the door latch (Fig. 4).
7. Check the door latch operation and then, install the door trim panel.

L-W-AND C-SERIES

1. Remove the trim panel and/or access hole cover plate.
2. Remove the retaining screw at the weatherstrip flange and the retaining nut inside the door at the front of the handle (Fig. 15).
3. Pull the handle from the door, and remove the two pads.
4. Position the pads to the door (add sealer) and install the retaining nut and retaining screw at the weatherstrip flange.

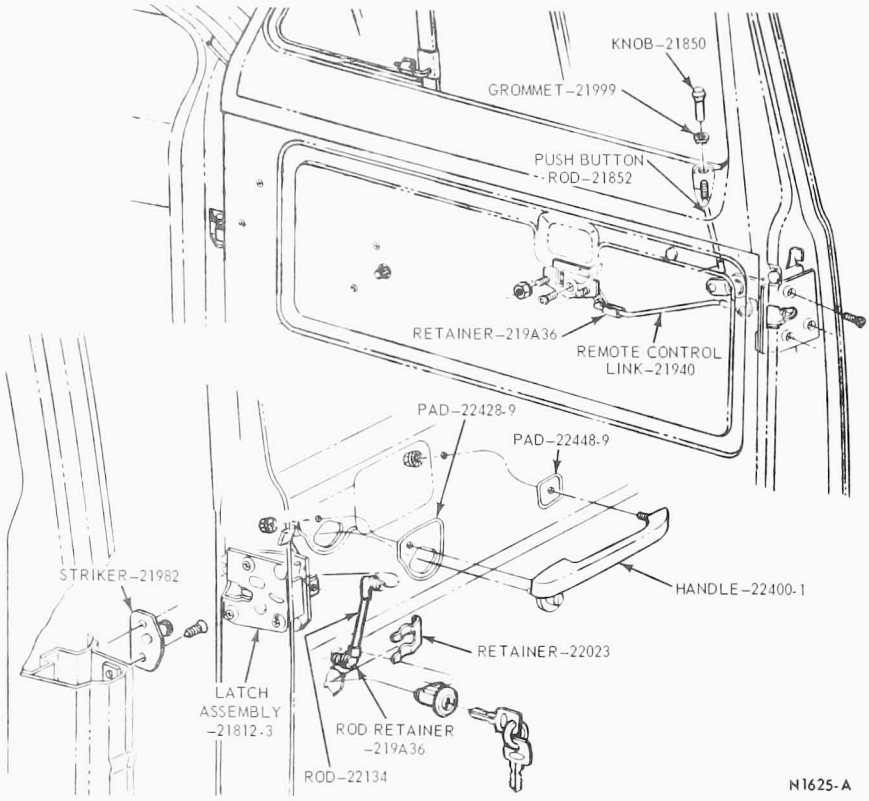

FIG. 10 Door Latch Installation—Econoline

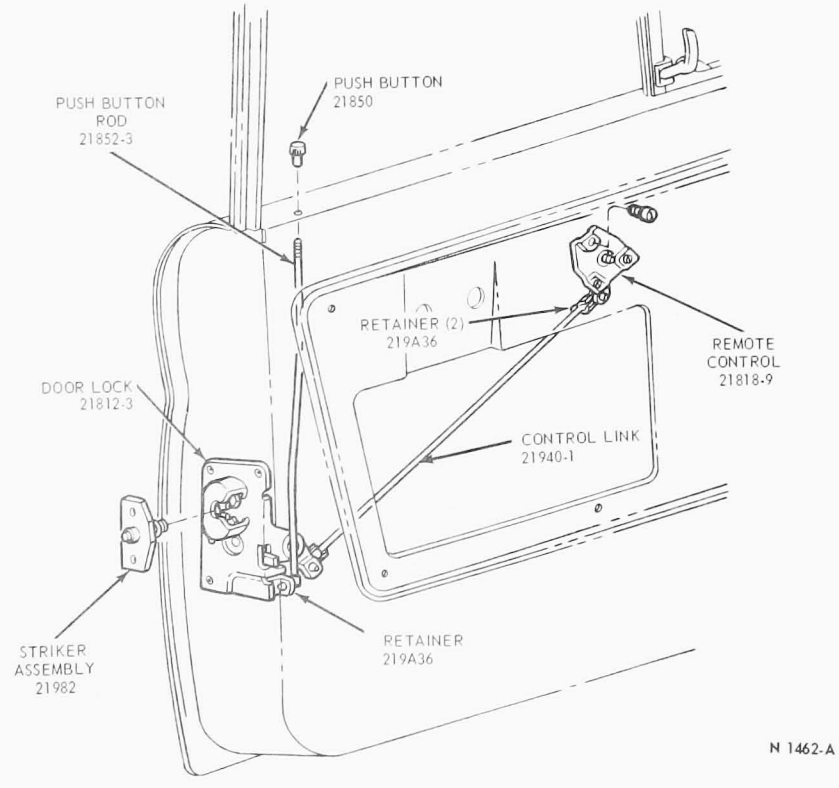

FIG. 11 Door Latch and Remote Control Installation— Bronco

5. Install the water shield if so equipped. The top edge should be cemented to the inner surface of the inner panel.
6. Install the access hole cover plate and/or trim panel.

DOOR OUTSIDE HANDLE—CARGO FRONT SIDE OR RIGHT REAR DOOR

ECONOLINE

Removal

1. Remove the trim panel from the door, if so equipped.
2. Remove two nuts retaining the outside handle to the door. Remove the handle and pads from the door (Fig. 16).

Installation

1. Position the two pads and the outside handle to the door, and install the two retaining nuts.
2. Check the operation of the latch, and install the trim panel, if so equipped.

DOOR OUTSIDE HANDLE

BRONCO

Removal

1. Remove the inside door handles, door access cover plate, and water shield.
2. Remove the retainer from the door lock control rod. Disconnect the rod from the outer door handle (Fig. 14).
3. Remove the retaining nut and lock washer that secure the front of the outside handle to the door panel.
4. Remove the screw and lock washer that secure the rear of the outside handle to the door from the weatherstrip flange.
5. Pull the outside door handle from the door, and remove the two door handle pads.

Installation

1. Position the door pads and the outside door handle (Fig. 14) on the door. When placing door pads on the door outer panel, make sure that the contour of the pads align with the contour of the handle mating surfaces.
2. Secure the front of the outside handle with a lock washer and retaining nut. Secure the rear end of the handle with the lock washer and screw.
3. Position the door lock control rod on the door handle and secure the rod with the retainer.
4. Install the water shield, door access cover, and the inside door handles.

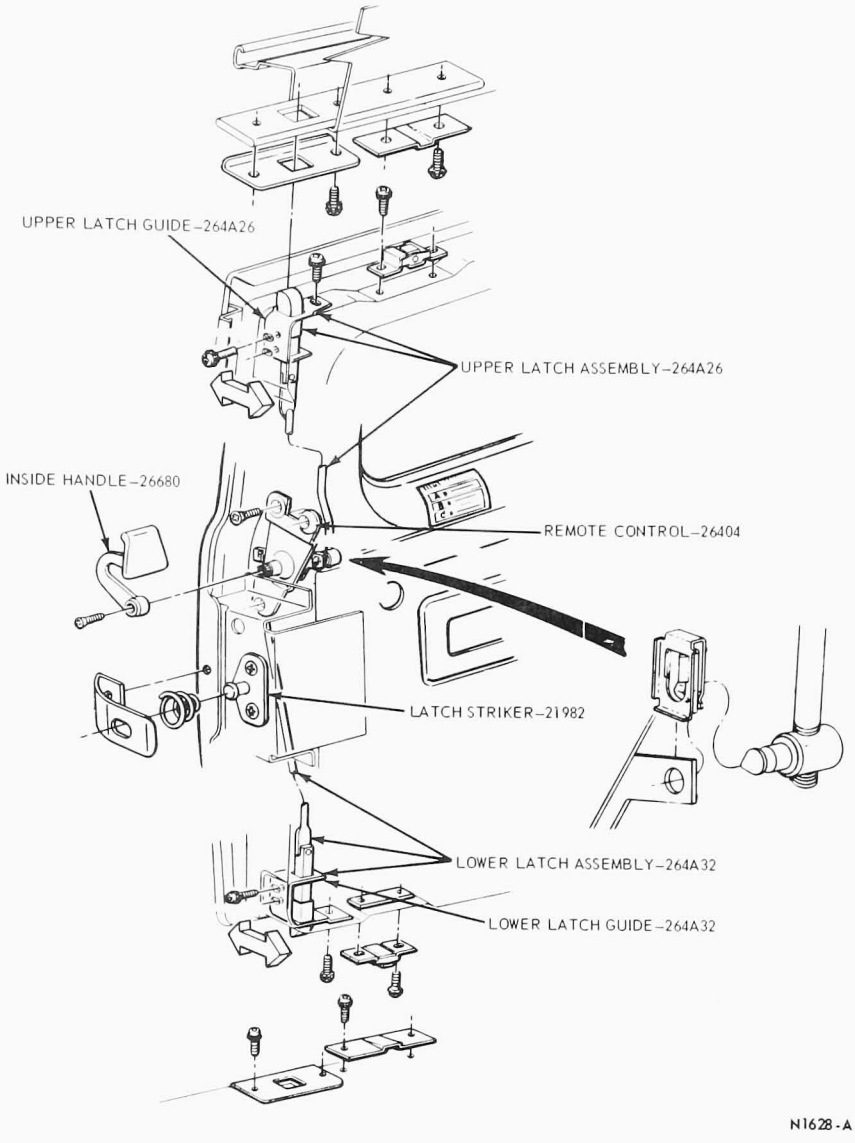

FIG. 12 Door Latch Installation—Cargo Rear Side or Left Rear Door—Econoline

Hood		21-02	21-02	21-02	21-03		N/A	21-02	N/A

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

F-AND B-SERIES

1. Open the hood and mark the hinge and latch assembly locations.
2. Loosen the hinge to fender apron attaching bolts until they are just snug (Fig. 1).
3. Adjust the hood up or down as required to obtain a flush fit between the hood and the top of the cowl panel. Then, tighten the hinge to fender apron attaching bolts.
4. Loosen the three hood latch assembly attaching screws.
5. Loosen the hinge to hood attaching bolts until they are just snug. Move the hood forward or rearward and from side to side as required for a proper hood fit. Then, tighten the hinge-to-hood attaching bolts and hood latch attaching screws.

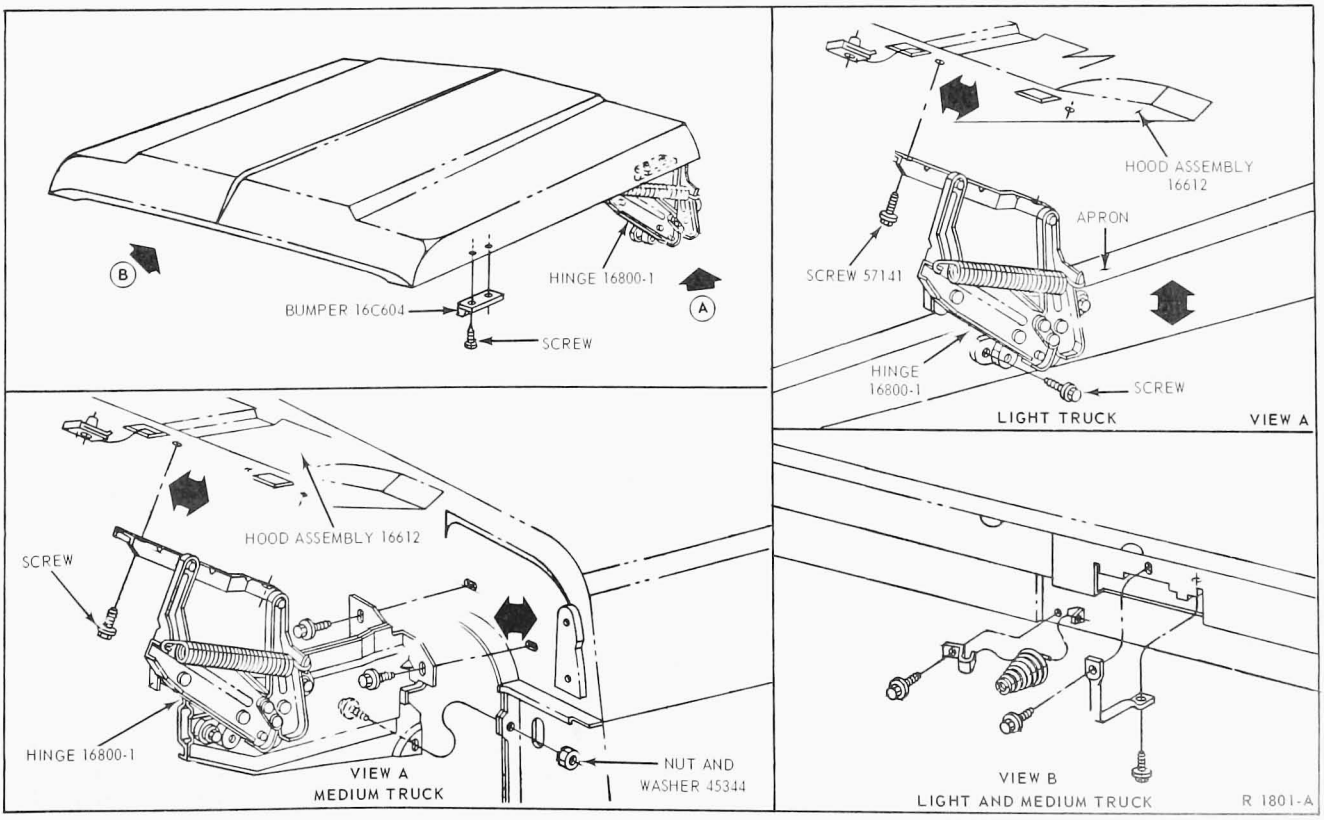

FIG. 1 Hood Hinge and Striker Installation—F-and B-Series

ECONOLINE

The hood can be adjusted fore-and-aft and up-and-down to obtain the proper clearance. To adjust the hood, loosen the hood-to-hinge attaching screws until they are just snug. Then, reposition the hood as required, and tighten the attaching screws. After the hood has been adjusted, check the hood latch and striker adjustment. Adjust the hood latch and striker if required (Fig. 2).

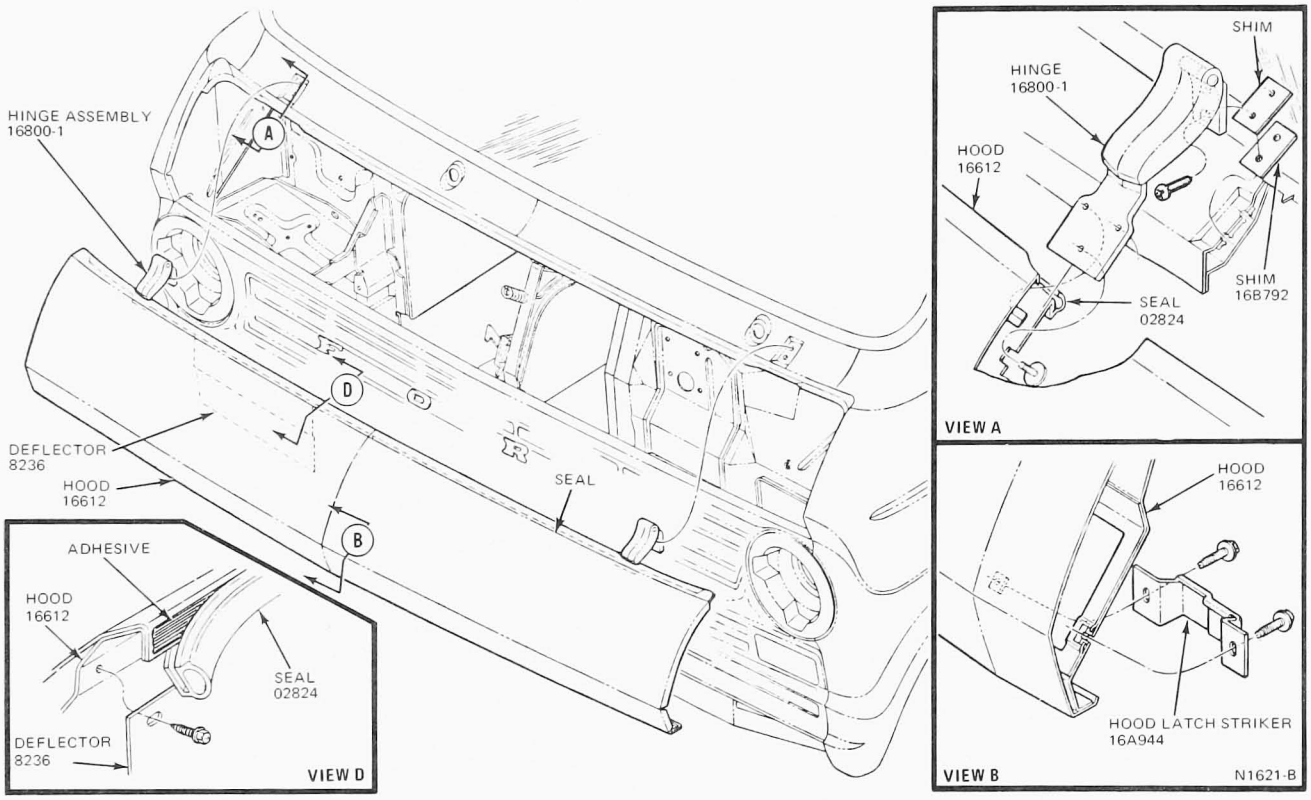

FIG. 2 Econoline Hood Installation

REMOVAL AND INSTALLATION

HOOD

F-AND B-SERIES

1. Remove the hood hinge bolts and with the aid of a helper, lift the hood off the hinges.
2. If the hood is to be replaced, transfer the hood latch components and ornaments to the new hood.
3. With the aid of a helper, position the hood on the hinges and install the hinge bolts just snug.
4. Adjust the hood for a proper fit by shifting the hood on the hinges, and tighten the hinge bolts (Fig. 1).
5. Adjust the hood latch for proper alignment.

ECONOLINE

Removal

1. Open the hood and prop the hood in the open position (Fig. 2).
2. Cover the cowl area to prevent paint damage.
3. Remove three screws attaching each hood hinge to the hood and remove the hood from the vehicle.
4. Remove the hood latch striker from the hood.

Installation

1. Position the hood to the hood hinges and install the attaching screws.
2. Adjust the hood (Adjustments) and tighten the hood-to-hinge attaching screws.
3. Install the hood latch striker on the hood and adjust the hood latch.

BRONCO

Removal

1. Unlatch and raise the hood and, with the aid of a helper holding the hood, remove the four screws that secure the left and right hood hinges to the cowl. Remove the hood.
2. Transfer the hood latching components and the windshield hold-down retainer to the new hood.

Installation

1. With the aid of a helper, position the hood on the cowl and attach each hinge with two screws. Tighten the screws just snug.
2. Adjust the hood for fore and aft fit by shifting the hood on the hinges. Tighten the hinge screws after fitting the hood.

L-SERIES

Removal

1. Tilt the hood assembly forward.
2. Remove the bolts securing the hood hinges to the hood. Support the hood assembly.
3. Disconnect the hood check cable by removing the clevis pin at each attaching point on the hood (Fig. 3).
4. Disconnect the hood wiring harness at the quick disconnect on the cowl.
5. Remove the hood from the vehicle.

Installation

1. Position the hood to the hood hinges and install the attaching bolts (1 each side).
2. Position the hood check cable to each attaching point and install the clevis pin.
3. Connect the wiring harness at the cowl.

HOOD—BUTTERFLY TYPE

L-SERIES

To remove the butterfly type hood, remove the screws retaining the piano type hinge to the hood panel (Fig. 4), and remove the hood from the vehicle.

HOOD HINGE

F-AND B-SERIES

1. Open the hood and prop it in the open position with a suitable prop.
2. Mark the locations of the hinges and remove the spring from both hinges.
3. Remove two screws attaching each hinge to the hood and remove the hood from the vehicle. Do not let the hood slide down and damage the cowl top.
4. Remove the hinge attaching bolts and remove the hinge from the vehicle.
5. Position the new hinges to the vehicle and install the attaching bolts snug.
6. Position the hood to the hinges and install the four attaching screws snug.
7. Remove the prop supporting the hood in the open position.
8. Close the hood and adjust the hood as outlined in Adjustments.

ECONOLINE

Removal

1. Open the hood and prop it in the open position.
2. Cover the cowl area to prevent paint damage.
3. Remove two hinge-to-body attaching screws (Fig. 2).
4. Remove three hinge-to-hood attaching screws and remove the hinge.

Installation

1. Position the hinge to the hood and install the three attaching screws snug.
2. Position the hinge and shim to the body and install the two attaching screws snug.
3. Adjust the hood (Adjustments) and tighten the five hinge attaching screws.
4. Remove the protective cover and close the hood.

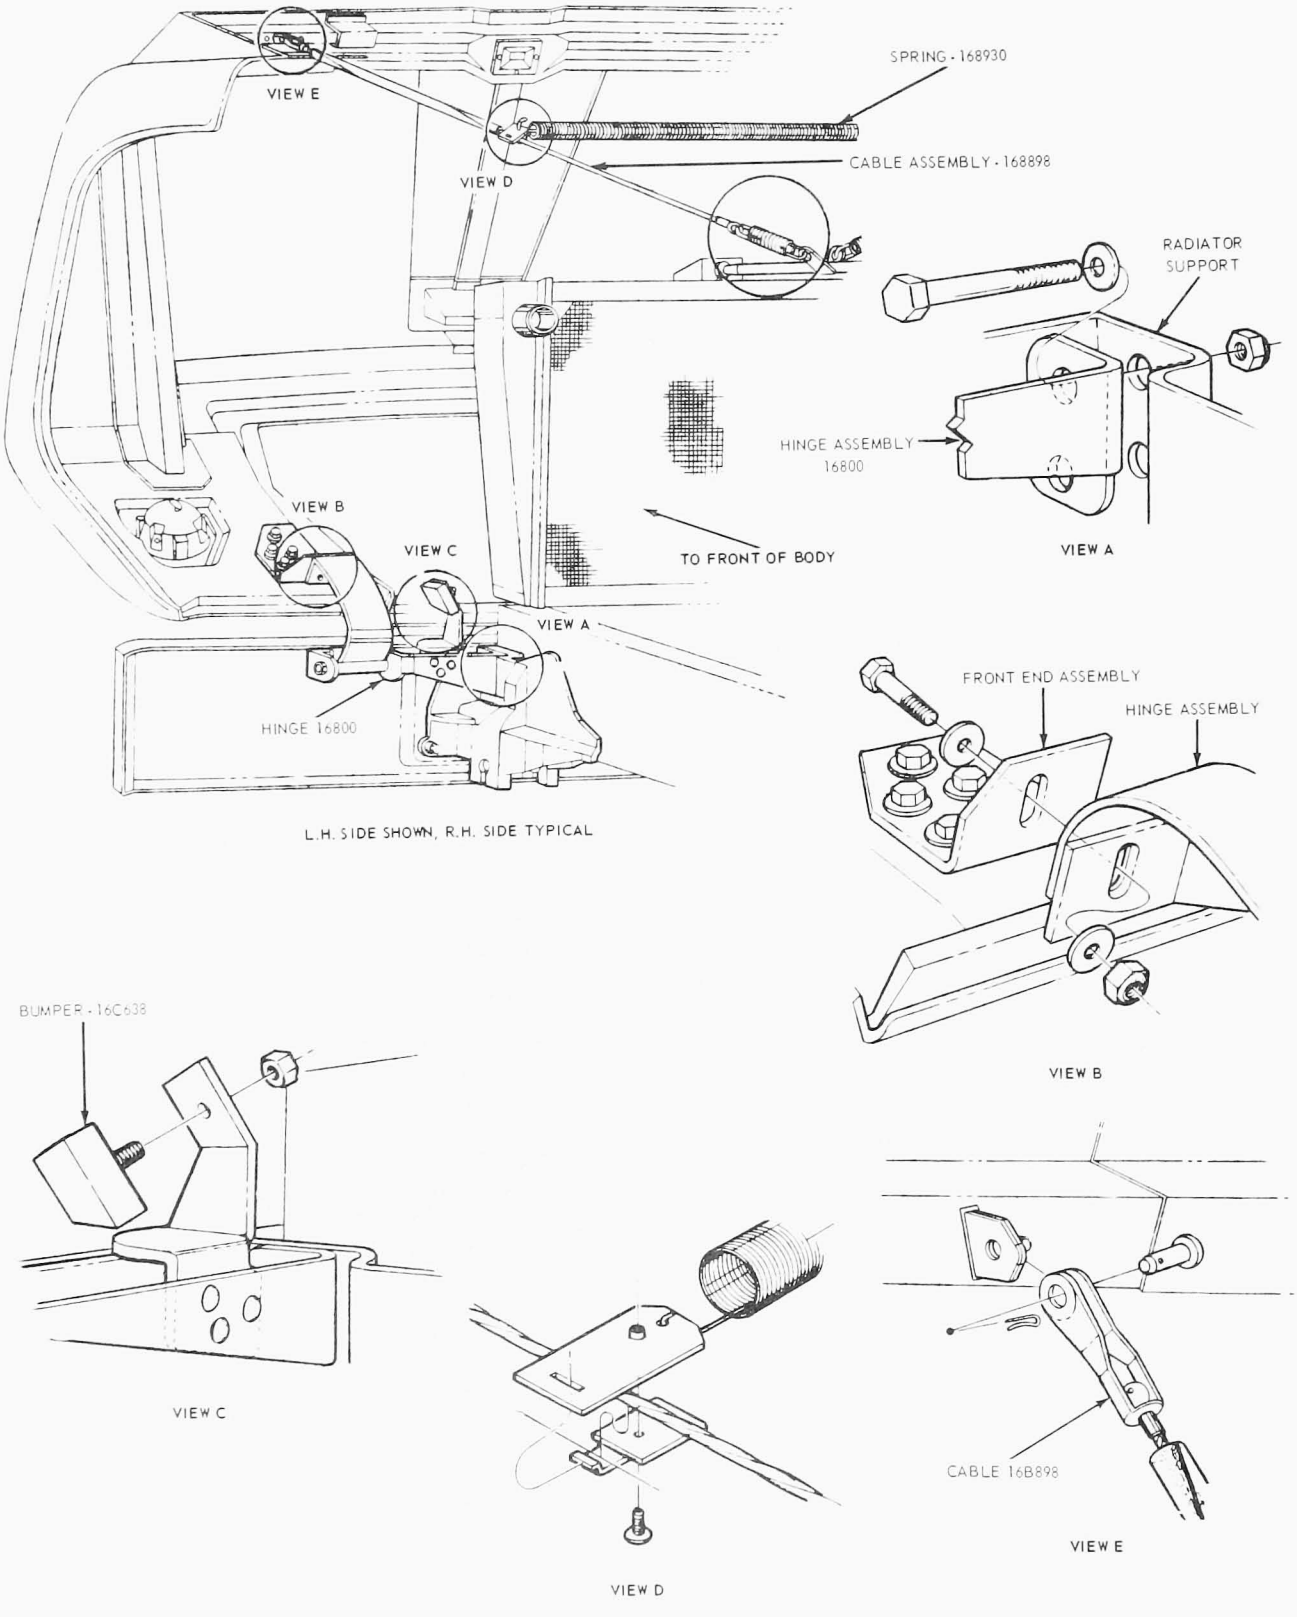

FIG. 3 Hood Assembly—L, LN and LT-Series

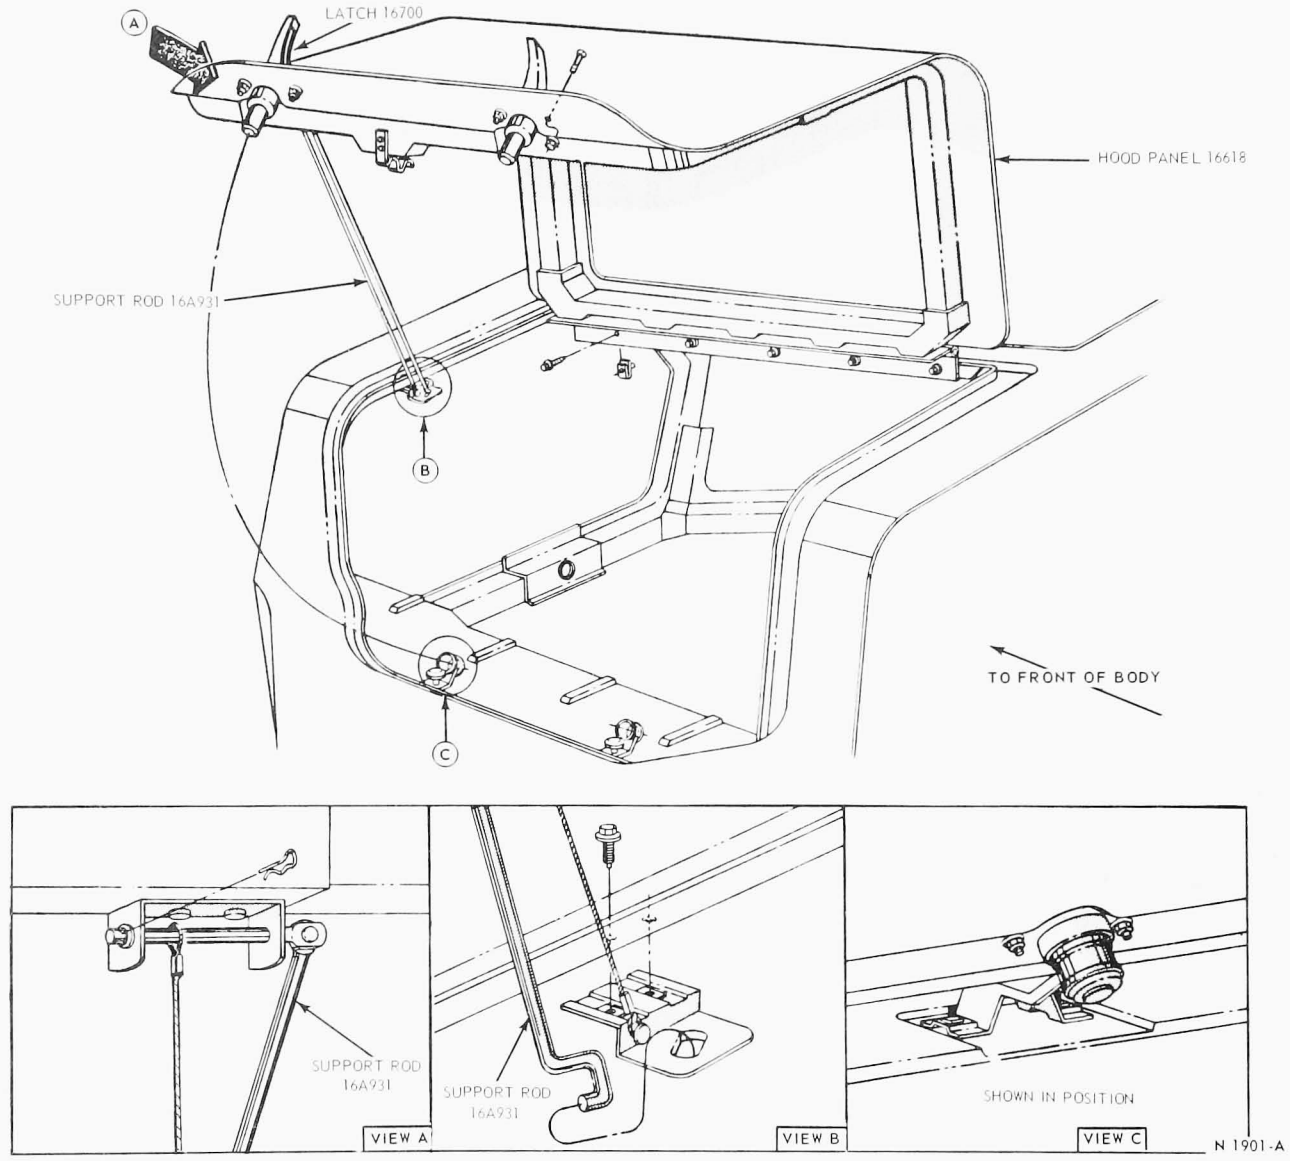

FIG. 4 Butterfly Type Hood—L-, LN-, and LT- Series

PART 44-31 Hood Latch

COMPONENT INDEX Applies To Models As Indicated	All Models	Bronco	Econoline	F-Series	L-Series	C-Series	W-Series	B-Series
ADJUSTMENTS Latch-Hood			31-01	31-01	31-01	N/A	N/A	31-01

Latch–Hood		31-04		31-04	31-04	N/A	N/A	31-04

A page number indicates that the item is for the vehicle(s) listed at the head of the column.
N/A indicates that the item is not applicable to the vehicle(s) listed.

ADJUSTMENTS

HOOD LATCH ADJUSTMENT

L-SERIES

The hood latch adjustment on L-Series vehicles provides a means of increasing or decreasing hood latch tension. To increase latch tension, turn the head of the latch clockwise (Fig. 1). Counterclockwise rotation decreases latch tension.

ECONOLINE

Before adjusting the hood latch mechanism, make certain that the hood is properly aligned. The hood latch assembly can be moved fore-and-aft to position the latch the proper distance from the striker (Fig. 2) for a snug hood fit. The latch striker can be adjusted up-and-down to obtain full depth hook engagement of the hood latch hook (Fig. 3) to assure positive hood retention.

1. Check for excessive hood free play to determine if the hood latch should be moved foreward or rearward. If free play is present when the hood is latched, the latch should be moved rearward. If the hood will not latch, the latch should be moved forward.
2. Loosen the hood latch attaching screw and washer assemblies and move the latch assembly forward or rearward as required to obtain a snug hood fit when the hood is latched (Fig. 2). Tighten the screw and washer assemblies and check the latch adjustment. Repeat this procedure as required to obtain positive hood latch engagement with a minimum of free play.
3. Check the hood latch hook to be sure it makes full hook engagement with the hood latch striker.
4. If the hook does not make full depth engagement, loosen the striker attaching screw and washer assemblies (Fig. 3) and reposition the striker to obtain full hook engagement. Then, tighten the screw and washer assemblies, and check the operation of the hood latch.

F-AND B-SERIES

Before adjusting the hood latch, make certain that the hood is properly aligned. The hood latch can be moved from side-to-side to obtain alignment with the hood latch hook. The hood latch hook can be adjusted up and down to obtain a snug hood fit (Figs. 4, 5 and 6).

1. Loosen the hood latch attaching screws just enough to move the latch.
2. Move the latch from side-to-side until it is aligned with the hood latch hook. Then, tighten the latch attaching screws.
3. Loosen the hood latch hook attaching screws just enough to move the latch hook.
4. Raise or lower the hood latch hook as required to obtain positive hood latch-to-hook engagement with a minimum of free play. Tighten the hood latch hook attaching screws. Check the hood latch to be sure it makes full engagement with the hood latch hook. If the hood latch does not make full engagement with the hood latch hook, loosen the hood latch hook attaching screws and reposition the hook to obtain full engagement. Then, tighten the attaching screws.

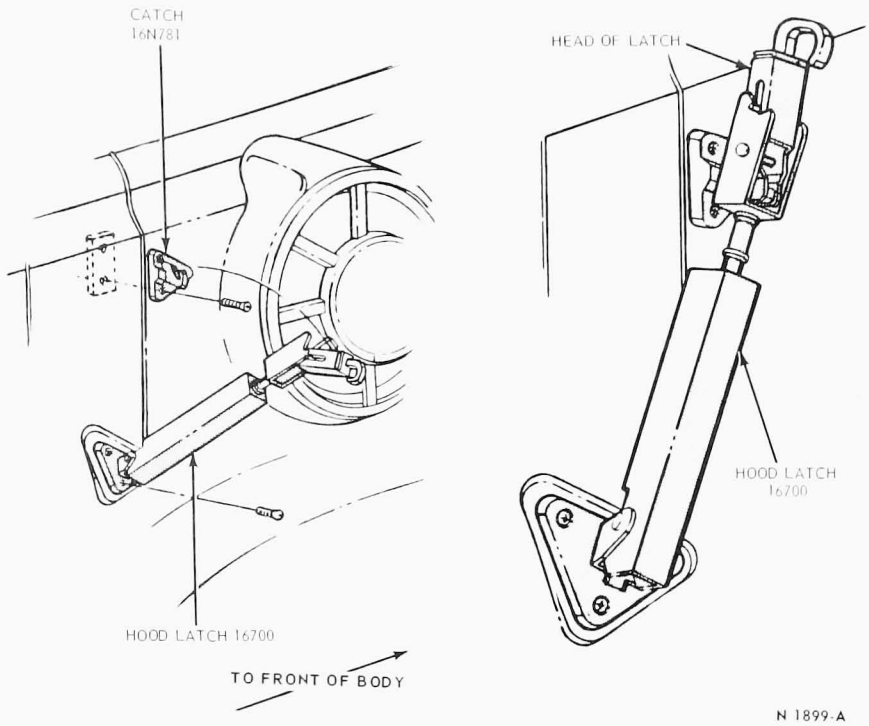

FIG. 1 Hood Latch Installation—L-Series

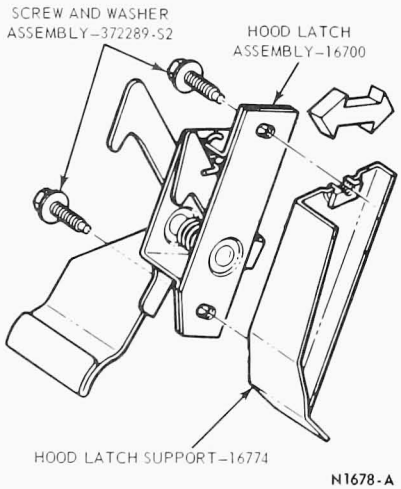

FIG. 2 Econoline Hood Latch Adjustment

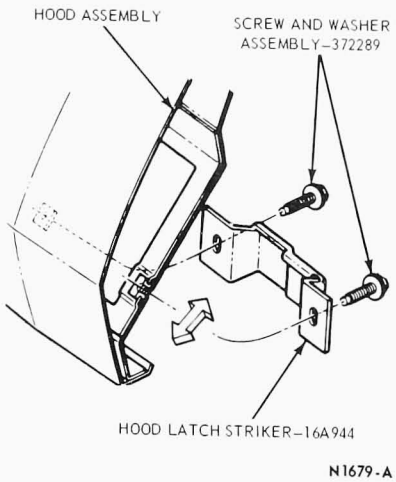

FIG. 3 Econoline Hood Latch Striker Adjustment

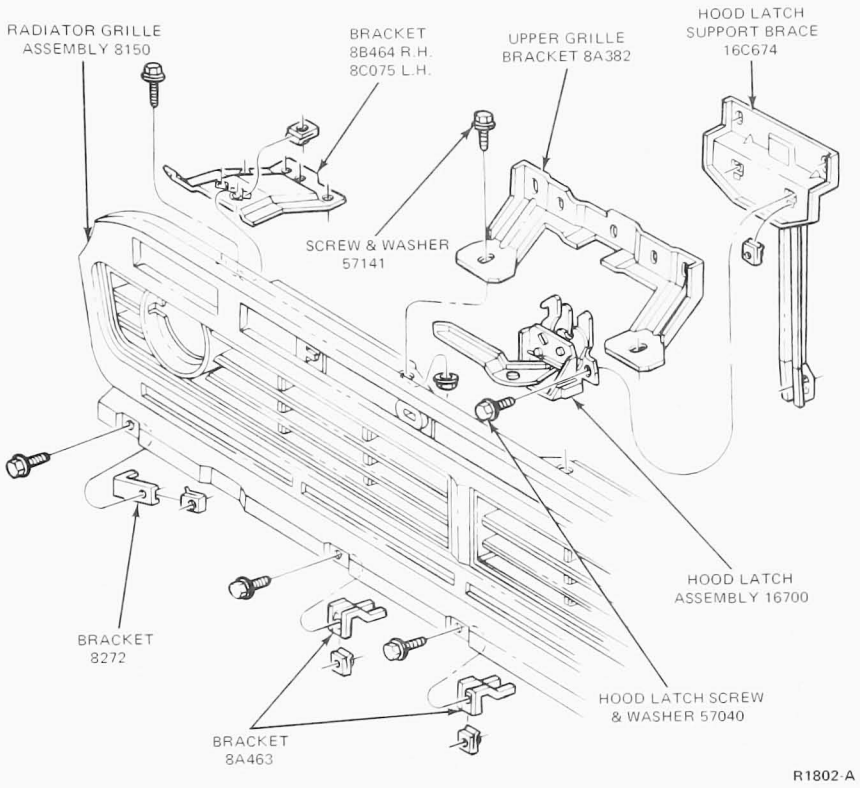

FIG. 4 Hood Latch Installation—F-100 through F-350

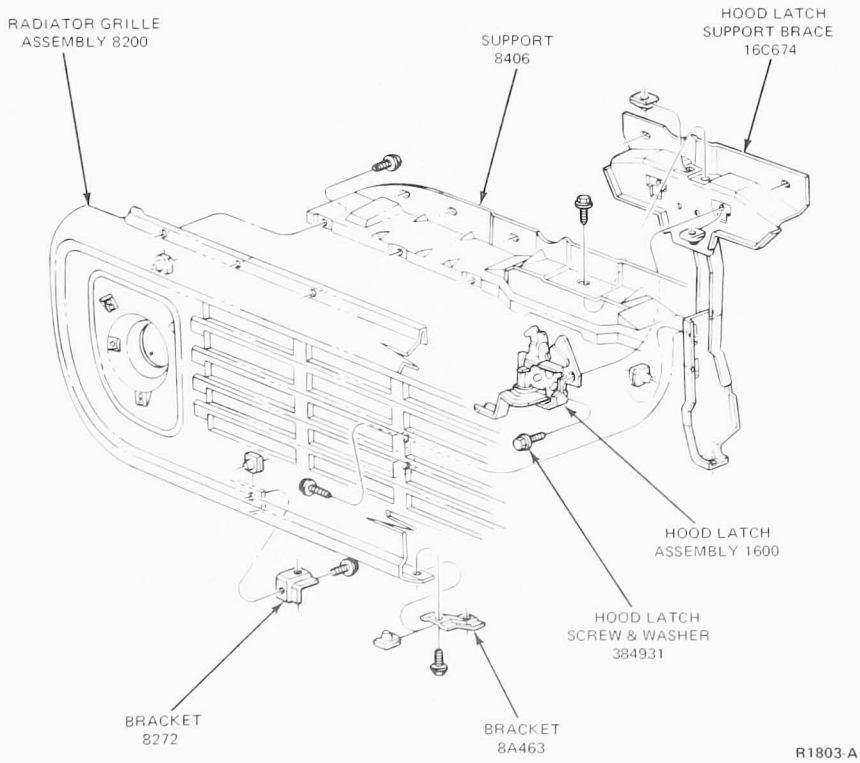

FIG. 5 Hood Latch Installation—F-500 Through F-750 and B-500 Through B-750 Series

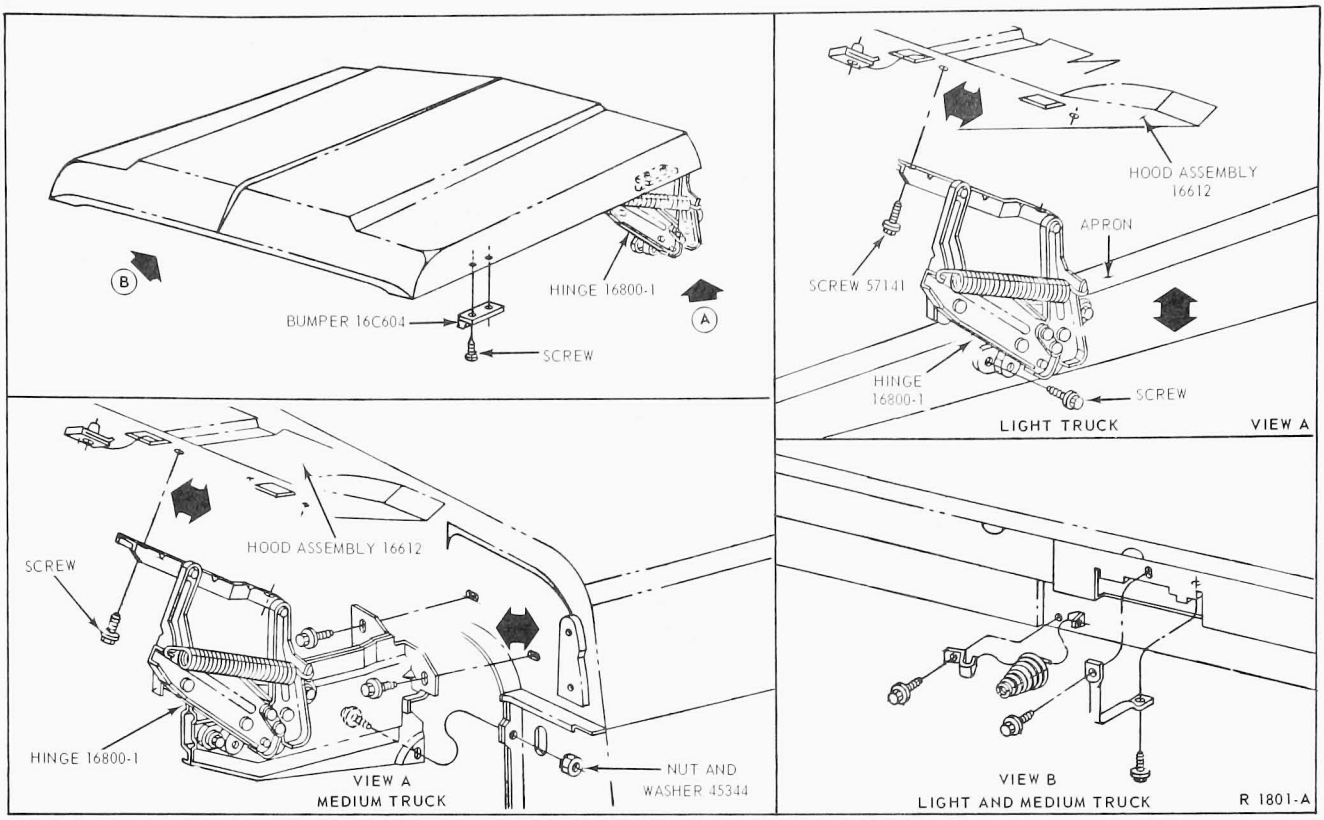

FIG. 6 Hood Latch Striker Installation—F-and B-Series

REMOVAL AND INSTALLATION

HOOD LATCH

F- AND B- SERIES

1. Open the hood and remove the hood latch attaching screws and remove the latch assembly from the hood.
2. Position the latch assembly to the hood and install the attaching screws snug but do not tighten.
3. Adjust the latch assembly for positive engagement with the hood latch hook and tighten the latch attaching screws.

L-SERIES

To remove the hood latch assembly, remove the six screws which retain the latch assembly to the hood and the cowl side panel (Fig. 1). Then remove the latch.

BRONCO

Removal

1. Unlatch and raise the hood. Secure the hood in the open position with the hood support rod.
2. Remove the four screws that secure the hood latch assembly to the latch bracket of the grille (Fig. 7). Remove the latch from the opening between the grille and radiator.
3. Remove the four jay nuts from the latch.

Installation

1. Position the four jay nuts on the latch.
2. Position the latch assembly on the underside of the latch bracket.
3. Secure the latch to the bracket with four screws. Do not tighten the screws.
4. Disengage the hood support rod from the hood and lower the hood to the latch. Shift the latch until the hood catch is centered with the latch opening. Tighten the screws securing the latch to its bracket and close the hood.

HOOD LATCH HOOK OR AUXILIARY CATCH STRIKER

F-500 THROUGH 750, 6000, 7000 AND B-SERIES

1. Remove two screws attaching the hood latch hook to radiator support and the grille upper support (Fig. 6) and remove the hook.
2. Position the hook to the grille upper support and the radiator support and install the two screws loose.
3. Adjust the hood latch mechanism as necessary for positive engagement of the hood latch and tighten the attaching screws.

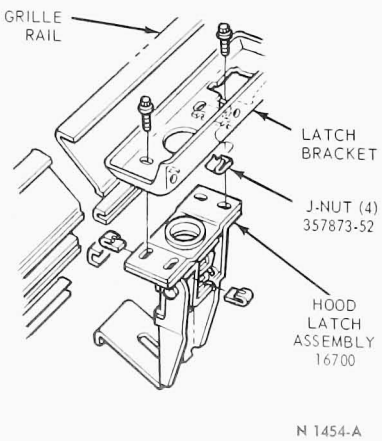

FIG. 7 Bronco Hood Latch Installation

PART 44-86 Tailgate—Bronco and Pickup

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION		Latch – Tailgate	86-02
Bracket – Tailgate Latch	86-01	Latch – Tailgate-on Body	86-01
Handle – Latch Release	86-02	Tailgate	86-02

REMOVAL AND INSTALLATION

TAILGATE-ON-BODY LATCH

STYLESIDE PICK-UP

1. Open the tailgate and remove two latch attaching screws and remove the latch (Fig. 1).
2. Position the latch to the body and install the two attaching screws snug.
3. Adjust the latch and tighten the screws securely.

TAILGATE SUPPORT, HANDLE AND LATCH BRACKET

STYLESIDE PICK-UP

Removal

1. Open the tailgate and disconnect the tailgate support arm from the latch bracket assembly as shown in Fig. 1. Then, remove the two upper arm attaching screws.
2. Remove three tailgate handle screws, disconnect the handle release links and remove the handle assembly.
3. Remove three latch bracket-to-tailgate attaching screws and remove the latch bracket assembly.

Installation

1. Position the latch bracket to the tailgate, connect the link to the latch

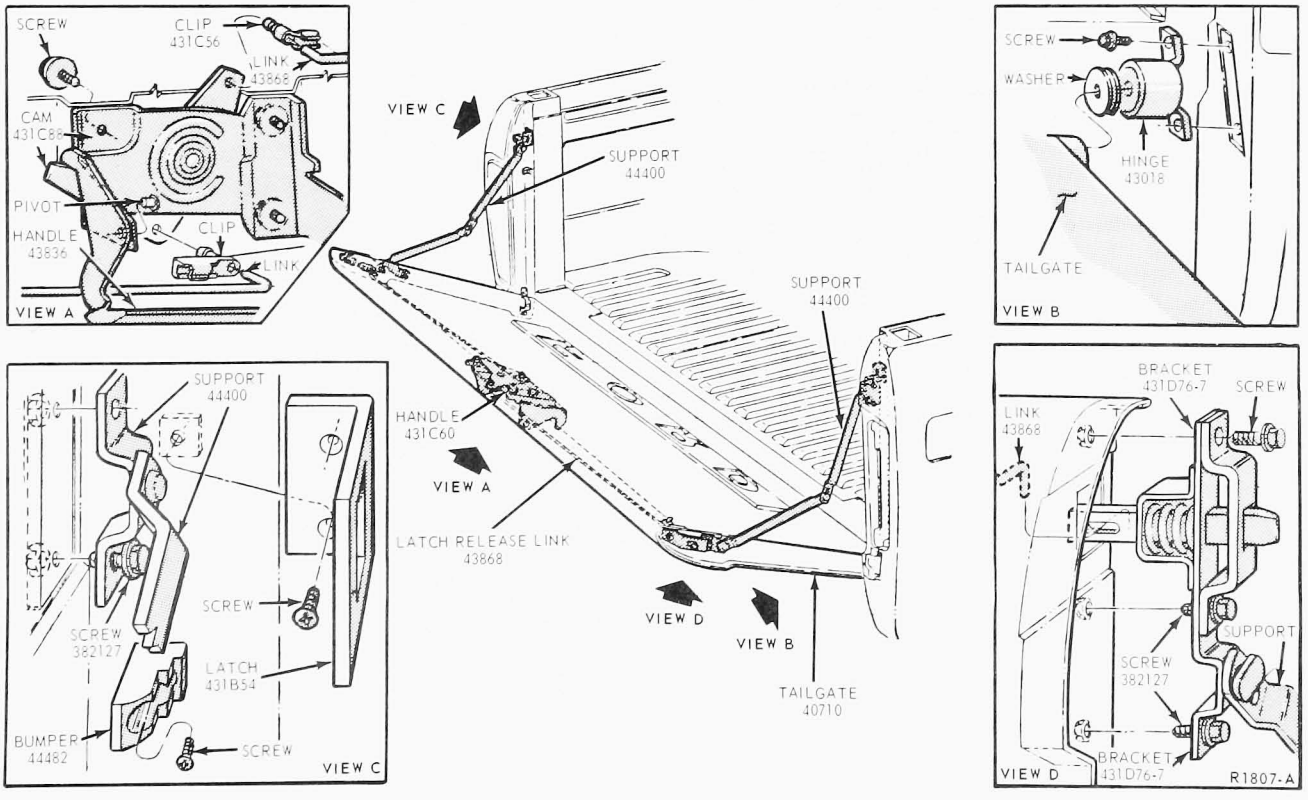

FIG. 1 Tailgate Installation—Styleside Pick-Up

bracket and install the attaching screws.
2. Position the tailgate handle to the tailgate. Connect the links to the center handle assembly and install the handle attaching screws.
3. Connect the tailgate support arm assembly to the latch bracket and install the two upper arm attaching screws.

TAILGATE

Open and support the tailgate assembly and remove the hinge attaching screws on each side of the tailgate (Fig. 1). Then, carefully raise the lower portion of the tailgate upward and disengage it from the tailgate latch brackets. If a new tailgate is being installed, transfer all mouldings, latches, hinges, brackets, links, clips and washers to the new tailgate.

BRONCO

Removal

1. Unlatch the tailgate handle and lower the tailgate (Fig. 2). Disconnect the left and right support assemblies at the tailgate.
2. Disconnect the license plate light wire at the connector. Pull the lead wire from the tailgate body rail.
3. Remove the four screw and washer assemblies that secure the left and right hinge assemblies (Fig. 2) to the body.
4. Remove the tailgate and the hinge assemblies.

Installation

1. Position the hinge assemblies on the tailgate and then position the tailgate on the body (Fig. 2).
2. Secure each hinge assembly to the body (Fig. 2) with two screw and washer assemblies.
3. Connect the support assemblies to the tailgate.
4. Position the license plate light lead in the tailgate body rail and connect the lead to its connector.

TAILGATE LATCH RELEASE HANDLE AND MOUNTING PLATE

BRONCO

Removal

1. Remove the two screw and washer assemblies that secure the release handle mounting plate assembly to the inner panel of the tailgate (Fig. 2).
2. Remove the four screw and washer assemblies that secure the release handle mounting plate assembly to the outer panel of the tailgate.
3. Pull the mounting plate assembly down and away from the outer panel, and remove the two hairpin clips and plain washers that secure the latch release links to the release lever.
4. Disconnect the links from the release lever and remove the mounting plate assembly from the tailgate.
5. Remove the nut assembly and washers that secure the release handle to the release lever bolt. Remove the release handle.

Installation

1. Position the release handle in the mounting plate assembly and attach it to the release lever with the latch release lever bolt, nut assembly, and washers.
2. Hold the mounting plate assembly close to the outer panel opening of the tailgate and position the release links on the release lever. Secure each release link with a plain washer and hairpin clip.
3. Slip the mounting plate assembly into the tailgate panel opening and secure it to the outer panel with four screw and washer assemblies.
4. Secure the mounting plate assembly to the inner panel with two screw and washer assemblies.

TAILGATE LATCH ASSEMBLY

BRONCO

Removal

1. Remove the tailgate handle assembly as described above.
2. Remove the two screw and washer assemblies that secure the latch assembly to the tailgate.
3. Remove the latch and link assembly from the tailgate.

Installation

1. Position the latch assembly on the link. Feed the latch and link assembly into the end of the tailgate and secure the latch assembly and bracket with two screw and washer assemblies. **The tapered side of the latch bolt must face forward.**
2. Install the tailgate handle as described above.

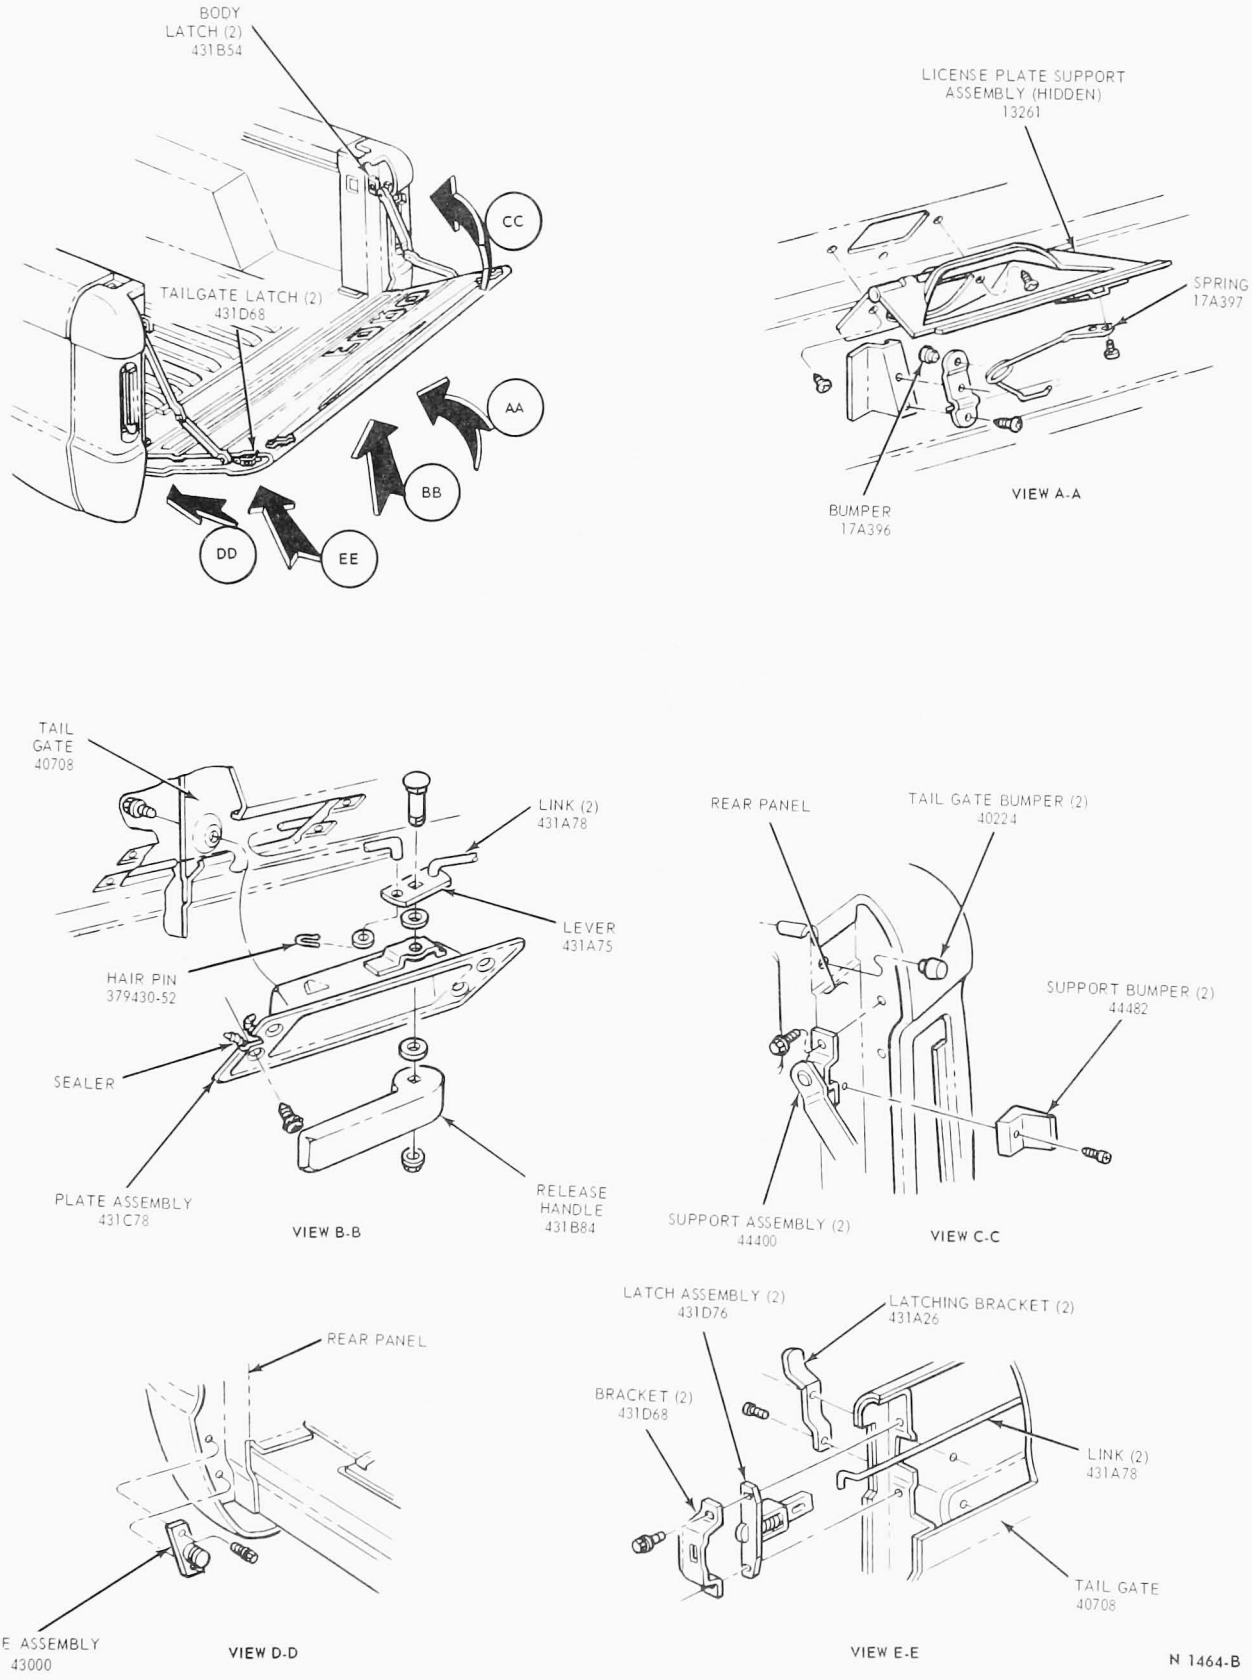

FIG. 2 Tailgate Installation—Bronco

PART 44-92 Liftgate, Hinges and Weatherstrip

Applies Only To Bronco

REMOVAL AND INSTALLATION

LIFTGATE

Removal

1. Unlatch the liftgate (Fig. 1), with the handle, and raise the liftgate. Using a helper to support the liftgate, remove the four screws that attach the left and right prop assemblies to the liftgate.
2. Remove the eight screws, lock washers, and nuts that secure the lift gate to the gate hinge (Fig. 1).
3. Remove the liftgate and sealer strip.

Installation

1. When replacing the liftgate assembly, transfer the glass, handle assembly, locking mechanism, and weatherstrip to the new liftgate.
2. Position the liftgate hinge on the mating body surface (Fig. 1), and secure it with eight screws, lock washers, and nuts.
3. Position the left and right prop assemblies (Fig. 1), on the liftgate and secure each prop assembly with two screws.

LIFTGATE HANDLE ASSEMBLY

Removal

1. Remove the two screws that secure the access plate (Fig. 1), on the liftgate, remove the access plate cover and disconnect the latch rods.
2. Hold the liftgate handle assembly in the unlatched position, and remove the two screws and nuts that secure the handle assembly to the liftgate.
3. Pull the handle assembly from the liftgate and remove the liftgate handle pad.

Installation

1. Position the handle pad and the handle assembly on the liftgate.
2. Turn the handle to the unlatched position. While holding the handle assembly and the pad in position, install the two screws and nuts securing the pad and the handle assembly to the liftgate and connect the latch rods.
3. Position the access plate on the liftgate and secure it with two screws.

LIFTGATE LOCK CYLINDER

Removal

1. Remove the liftgate handle from the liftgate.
2. Remove the spring retaining pin from the liftgate handle and remove the spring and washers (Fig. 1).
3. Remove the collar from the handle.
4. Depress the lock cylinder retaining pin, and remove the lock cylinder from the handle.

Installation

1. Insert the lock cylinder into the handle. Be sure the lock cylinder retaining pin is engaged in the pin hole.
2. Position the collar, spring, and washers on the handle, and install the spring retaining pin (Fig. 1).
3. Install the handle in the liftgate.

LIFTGATE LATCH BOLT ASSEMBLY

Removal

1. Open the liftgate and support the gate on the prop assemblies.
2. Remove the inside cover plate at the outside handle (Fig. 1).
3. Disconnect the latch actuating rod from the lock bracket (Fig. 1).
4. Remove the cover plate at the latch bolt.
5. Remove two screws attaching the latch bolt bracket to the liftgate, and remove the latch bolt assembly and actuating rod from the liftgate.
6. Remove the pin and remove the rod from the latch bolt (Fig. 1).

Installation

1. Position the actuating rod to the latch bolt assembly and install the pin (Fig. 1).
2. Position the latch bolt assembly and rod in the liftgate, and install the two latch bolt assembly attaching screws.
3. Install the latch bolt cover plate.
4. Connect the latch actuating rod to the lock bracket (Fig. 1).
5. Install the outside handle cover plate.

PART 45-01 Interior Trim—General Service

CLEANING AND INSPECTION

1. Vacuum and/or whisk broom upholstery, trim and floor covering.
2. Remove any spots on upholstery using;
   a. Ford Automotive Fabric Spot Lifter (19526) or
   b. Ford Spot Remover (19521) or
   c. Both

   Use each product per label instructions.
3. Shampoo upholstery and carpeting using Ford Kar Kleen (19525) as directed on label.

PART 45-03 Door Trim Panels

REMOVAL AND INSTALLATION

DOOR-TRIM PANEL

BRONCO

Since all of the interior trim panels are retained to the body panels with screws, spring clips and/or metal strips, the removal and installation procedures are obvious. Access to some of these panels, however, requires prior removal of other parts. The pertinent removal procedures are outlined as follows:

To remove the door trim panels, refer to Figure 1. The armrest, inside door handle and window regulator handle must be removed. Then, remove the trim panel retaining screws, spring clips, retainers and the trim panel.

ECONOLINE

Removal

1. Remove the arm rest retaining screws and remove the arm rest from the door inner panel (Fig. 2).
2. Remove the four retaining screws from the door inside shroud and remove the shroud.
3. Remove the screws retaining the door trim panel and remove the trim panel.

Installation

1. Position the door trim panel to the trim panel retainers and install the retaining screws.
2. Position the door inside shroud to the door and install the retaining screws.
3. Install the arm rest to the door inside panel.

L-C AND W-SERIES

Removal

1. Remove the retaining screws and arm rest assembly if so equipped.
2. On models so equipped, remove the trim moulding assembly from the metal panel by unsnapping the retainers (Fig. 3). If equipped with a trim panel assembly, the trim panel will come off when the moulding is removed.
3. Remove the retaining screws and

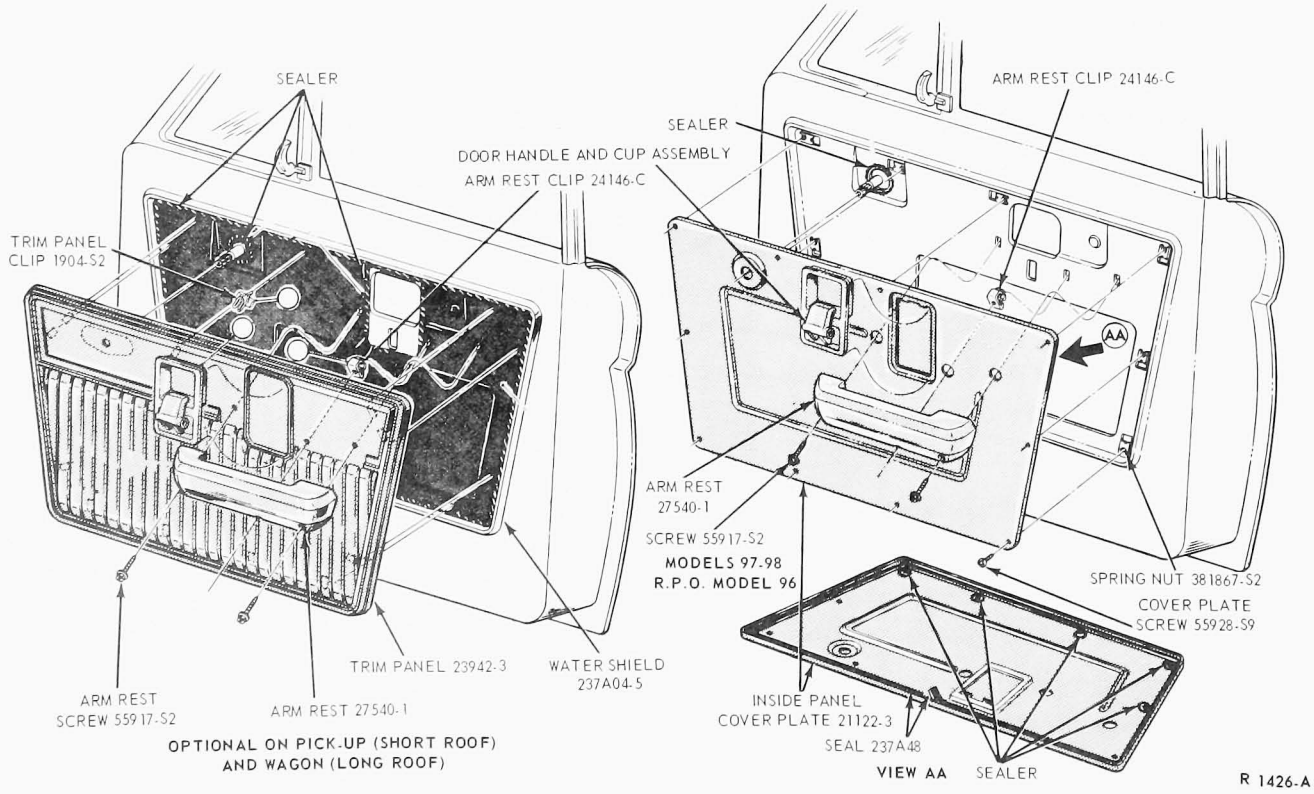

FIG. 1 Bronco Door Trim Panel Installation

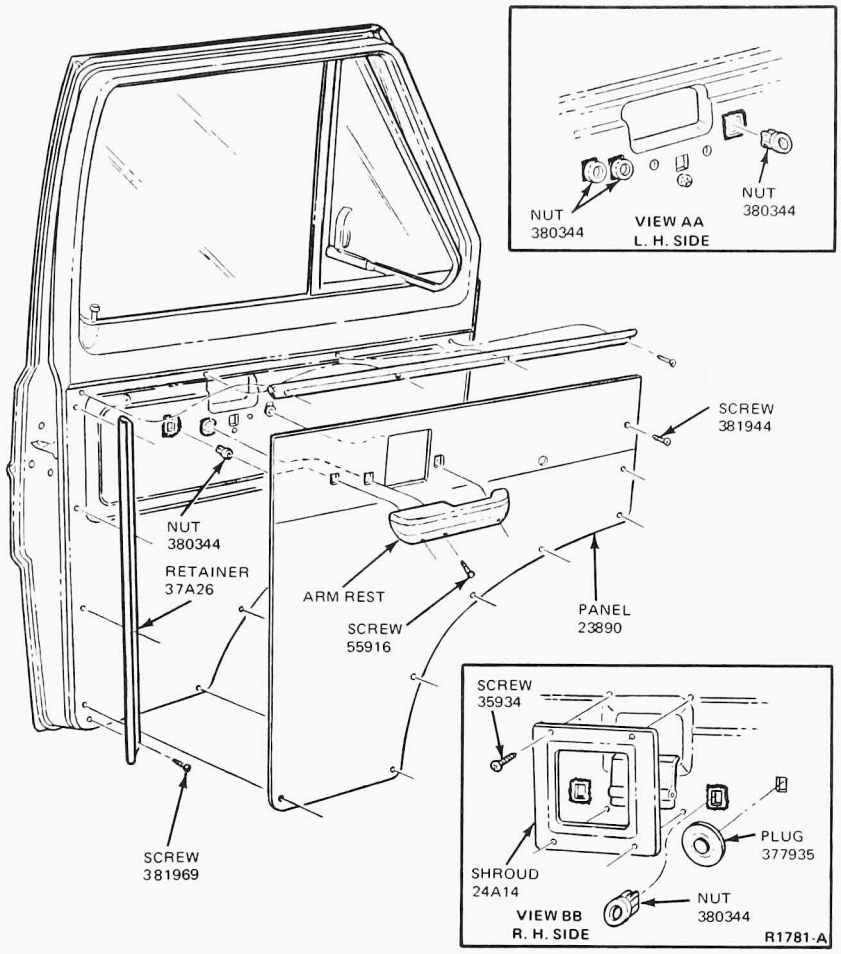

FIG. 2 Econoline Door Trim Panel Installation

remove the metal panel from the door (Fig. 3).

Installation

1. Make sure that the spring nuts are properly positioned around the metal panel opening in the door. Position the sealer to the perimeter of the metal panel, install the panel to the door, and secure with the retaining screws (Fig. 3).
2. On models equipped with a trim moulding assembly, position the moulding to the metal panel and snap it into place. If the door is also equipped with a trim panel assembly, position the trim panel to the metal panel first; and, then, secure the trim panel in place by installing the trim moulding (Fig. 3).
3. If so equipped, install the arm rest assembly and retaining screws.

F-SERIES

The door trim panel installation is shown in Fig. 6. To remove the trim panel, remove the finger tip plate screws. Remove the window regulator and door remote handle. Then, unsnap the 8 retainer clips around the perimeter of the trim panel. The clips are located as follows: three along the top and bottom and one at each end (Fig. 6).

SLIDING DOOR TRIM PANEL

ECONOLINE

Remove the retaining screws and remove the panel (Figs. 4 and 5).

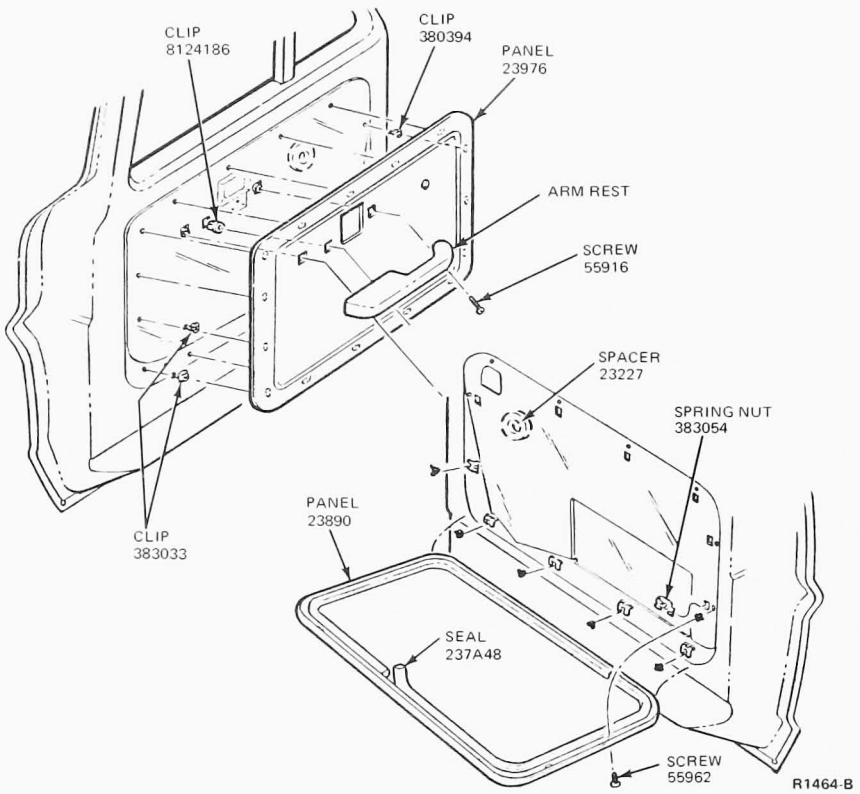

FIG. 3 Door Trim Panel Installation—Except Bronco and Econoline—Typical

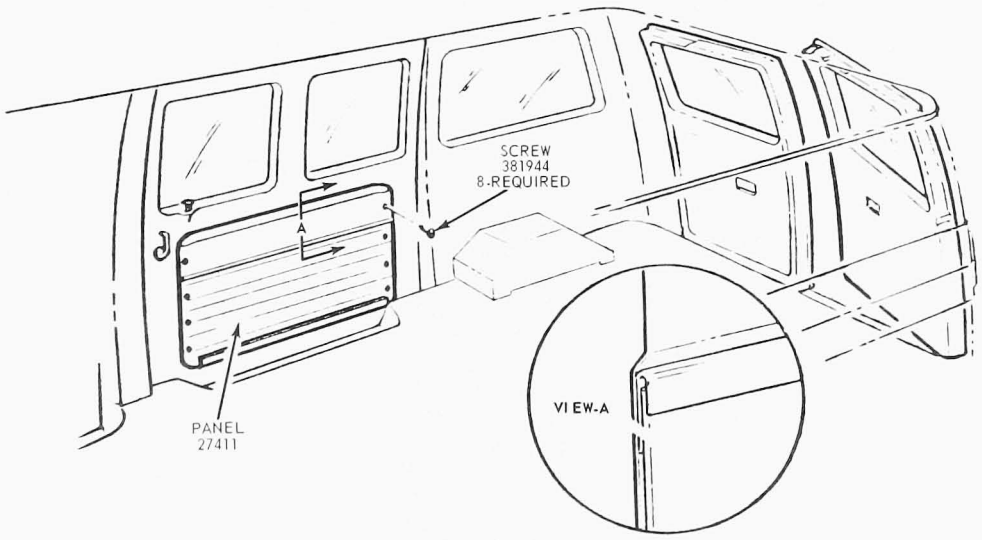

FIG. 4 Sliding Cargo Door—Trim Panel—Econoline

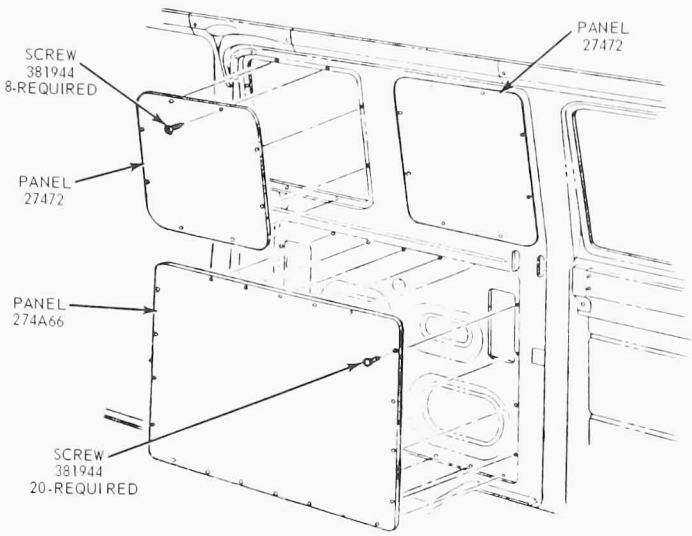

FIG. 5 Sliding Cargo Door—Trim Panels—Econoline

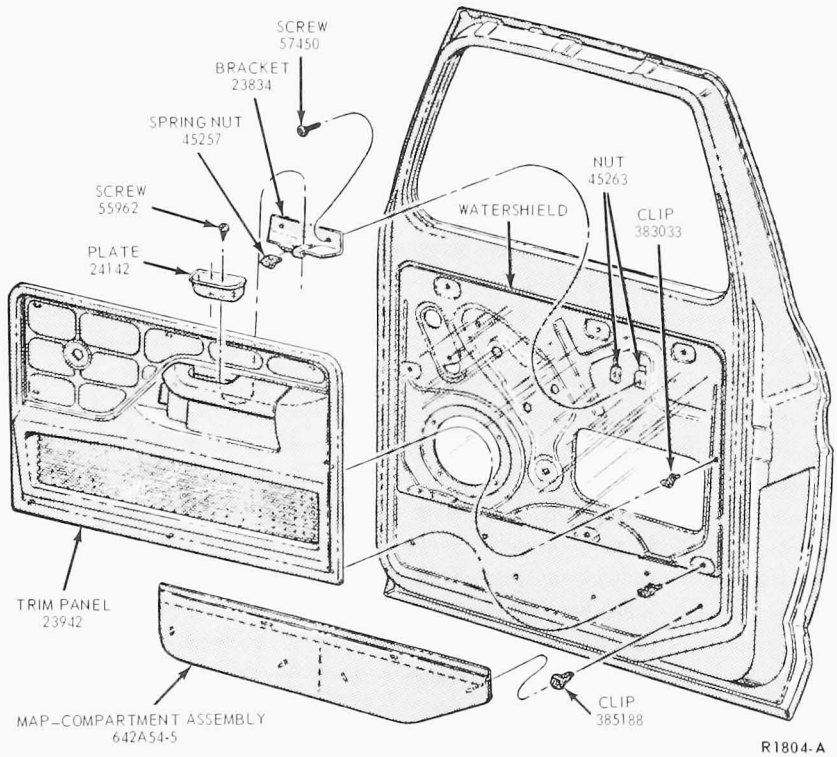

FIG. 6 Door Trim Panel Installation—F-Series

PART 45-11 Quarter Trim Panels

Applies To Econoline Only

REMOVAL AND INSTALLATION

QUARTER TRIM PANEL

ECONOLINE

Since all of the interior trim panels are retained to the body panels with screws and/or metal strips, the Removal and Installation procedures are obvious. Access to some of these panels, however, requires prior removal of other parts. The pertinent removal procedures are outlined as follows:

Before removing the left side trim panel, slide the driver's seat forward.

Before removing the right side trim panel, remove the right seat assembly from the vehicle (Group 41).

BACK WINDOW TRIM—UPPER PANEL

Econoline

Remove the two retaining screws, and remove the dome light glass and lens.

SIDE TRIM PANELS

Front and center—trim panel, left side. Remove the center passenger seat.

Rear left side—Remove the rear passenger seat.

Right rear side—Remove the rear passenger seat and the spare wheel and tire (For Seat Removal, See Group 41).

PART 45-16 Mouldings

Applies To Econoline Only

REMOVAL AND INSTALLATION

MOULDINGS

ECONOLINE

The installation of the fiberglass interior mouldings are shown in Fig. 1. In most instances, one moulding overlaps another moulding. If this condition is found, it will be necessary to loosen or remove the overlapping moulding before removal of the desired moulding. Also, the window latch retaining screws must be removed (if so equipped) to replace the window moulding.

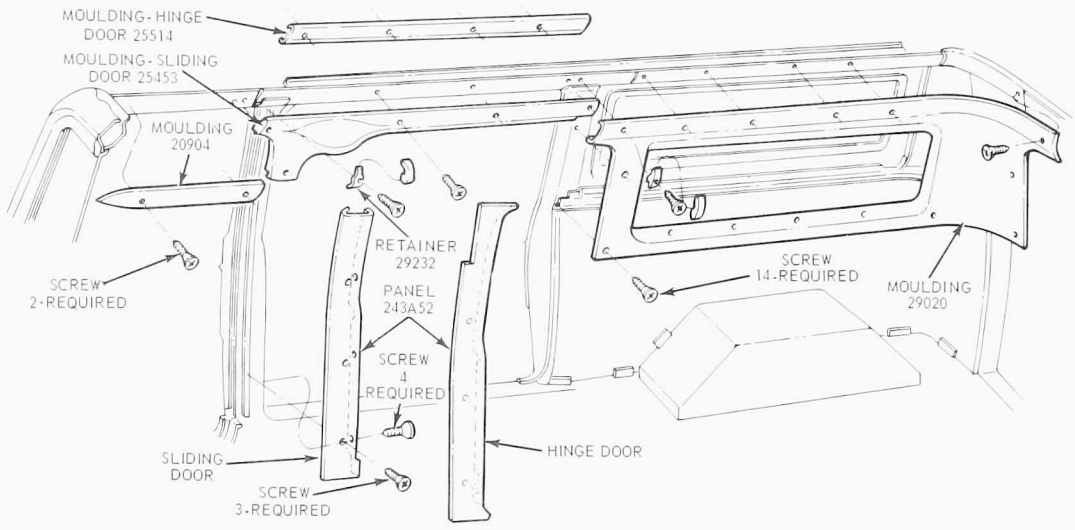

FIG. 1 Interior Fiberglass Mouldings—Econoline

PART 45-26 Carpets and Floor Mats

REMOVAL AND INSTALLATION

CARPETS AND FLOOR MATS

On vehicles equipped with a floor shift, remove the gear shift lever boot and retainer assembly before removing the mat or carpet, (if so equipped).

Remove all mat or carpet retaining screws. Remove the right and left door sill scuff plates and remove the mat or carpet.

PART 45-41 Headlining

REMOVAL AND INSTALLATION

ECONOLINE

1. Remove the trim panel retaining screws located at the inside centerline of the vehicle.
2. Unsnap the trim panel retainers. Unscrew the screws retaining the forward trim panel section to the roof inner panel.
3. Bow each trim panel section downward at the center of the vehicle and remove the trim panel from the retaining clips.
4. Position each trim panel section in the retaining clips. Snap the trim panel retainers in place. Install the screws that retain the trim panel forward section to the roof inner panel.
5. Install the retaining screws at the centerline of the vehicle.

BRONCO

Removal

The roof headlining is divided into two panels, front and rear. The two panels join at the headlining front support to which they are held by a retainer that extends across the width of the panels. The rear panel is also held to the headlining rear support by two screws. Both panels are retained by screws around their perimeters (Fig. 1).

To remove either panel, first remove the headlining retainer (4 screws).

To remove the front panel, remove seven retaining screws (3 at each side rail and 1 at the windshield header).

To remove the rear panel, first remove the panel-to-rear support screws at right and left center of the panel; and then remove the fourteen perimeter retaining screws (4 along each side rail and 6 across the rear window header).

Installation

1. Position the rear trim panel (Model 98) to the vehicle and install the retaining screws.
2. Position the front trim panel to the vehicle and install the retaining screws.
3. Fasten the roof moulding in position with the retaining screws.

F-SERIES

The headlining is held to the roof panel with trim mouldings as shown in Fig. 2. To remove headlining, remove 12

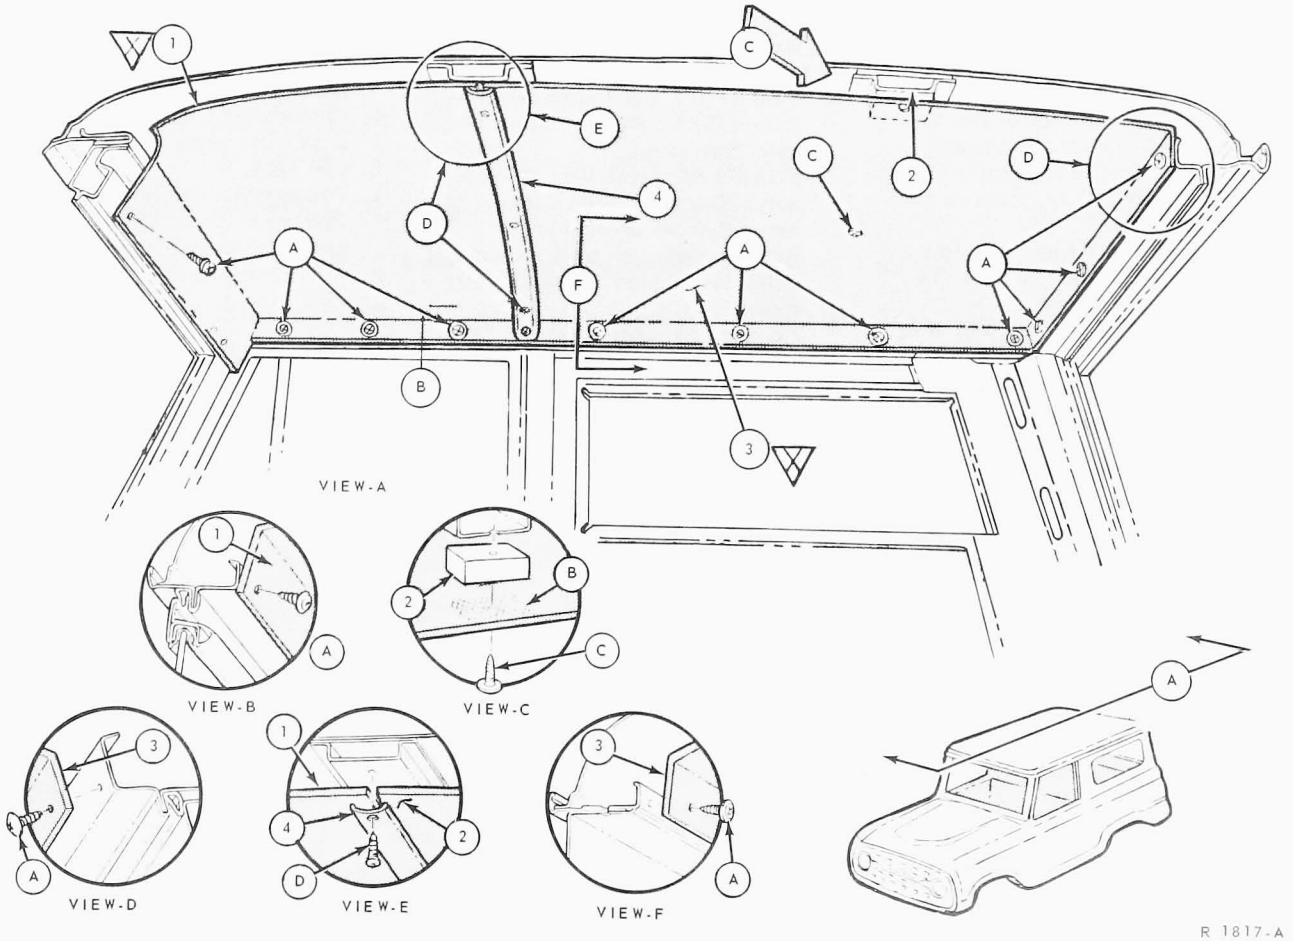

FIG. 1 Roof Trim Panel Installation—Bronco

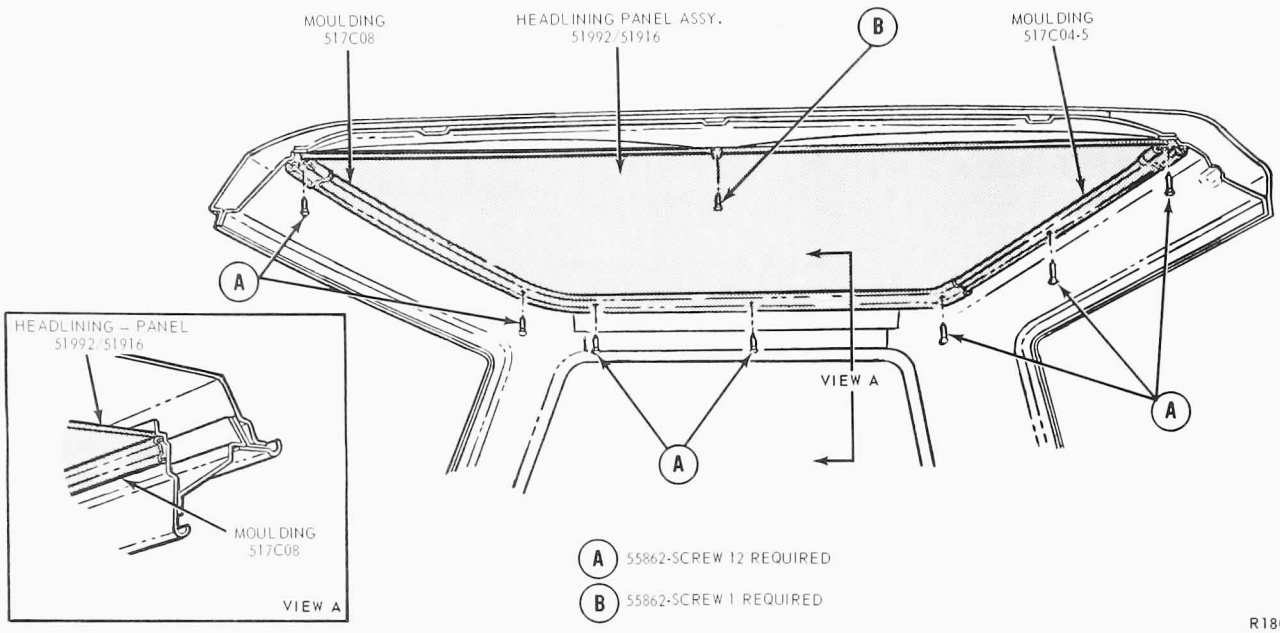

FIG. 2 Roof Trim Panel Installation—F-Series

moulding attaching screws and remove the mouldings and headlining.

L-SERIES

1. Remove the coat hook and rear corner trim moulding.
2. Unsnap or remove screws and remove the roof trim mouldings.
3. Remove the roof trim panel retaining screws and remove the roof trim panel.
4. Position the roof trim panel to the roof and install the roof trim panel retaining screws.
5. Position and install the roof trim mouldings (Fig. 3 and 4).
6. Install the roof corner moulding and the coat hook.

C-AND W-SERIES

Removal

1. Start at one side and work across. Remove the side panel retaining screws and the side panel (Fig. 3 and 4).
2. Remove the metal strip retaining screws, the metal strip, and the roof outer trim panel.
3. Remove the dome light (C-Series only). Disconnect the dome light wires. Remove the coat hook.
4. Remove the other metal retaining strip, and remove the roof center trim panel.
5. Remove the retaining screws from the remaining side panel, and remove the side panel and the remaining roof outer trim panel.

Installation

1. Position the roof side trim panel and install the retaining screws.
2. Position the roof outer trim panel, and clinch the retaining tabs.
3. Position the center panel, and clinch the retaining tabs.
4. Connect the dome light wires, and install the dome light. Install the coat hook.
5. Position the remaining roof outer trim panel, clinch the retaining tabs, and install the other roof side panel.
6. Install the metal retaining strips.

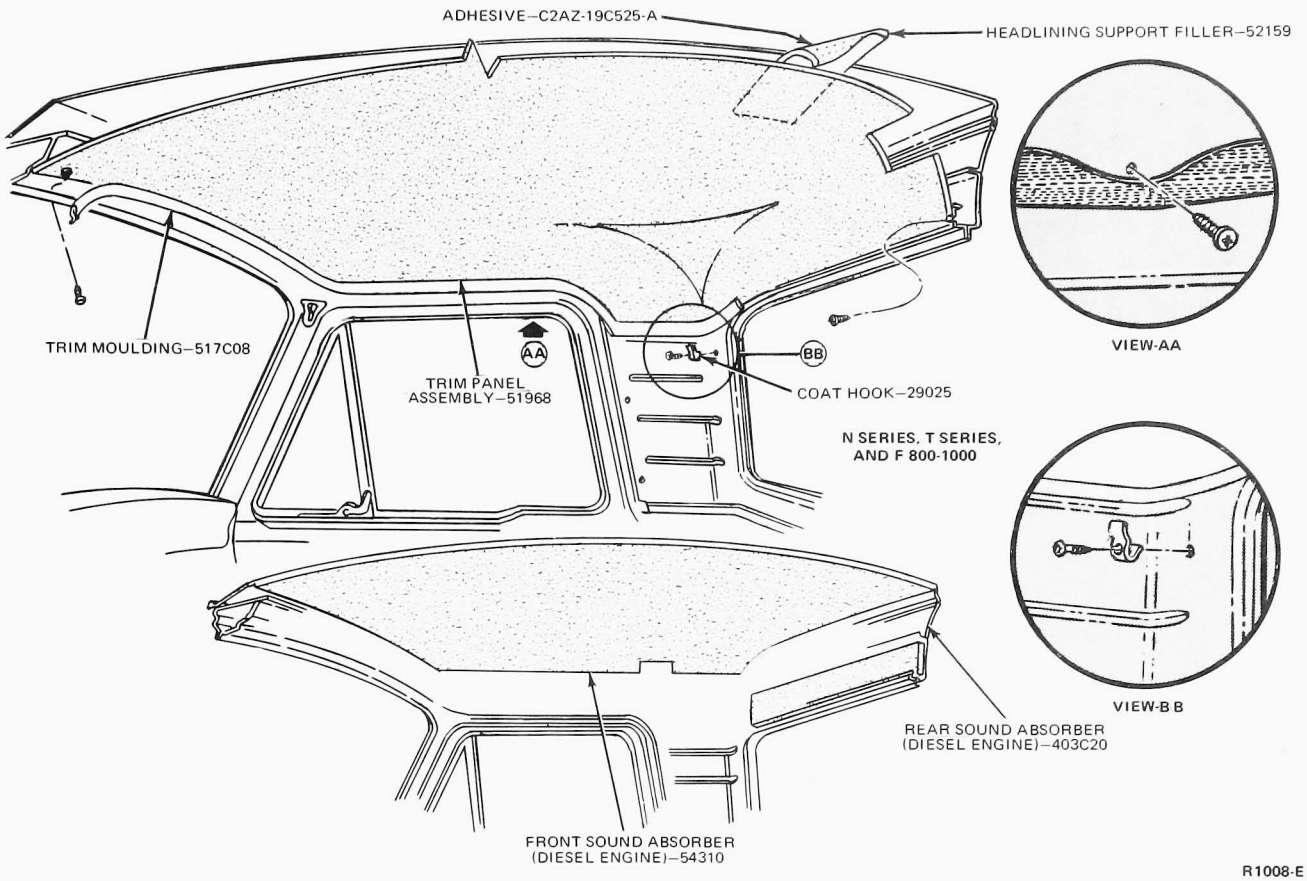

FIG. 3 Roof Trim Panel Installation—L-Series

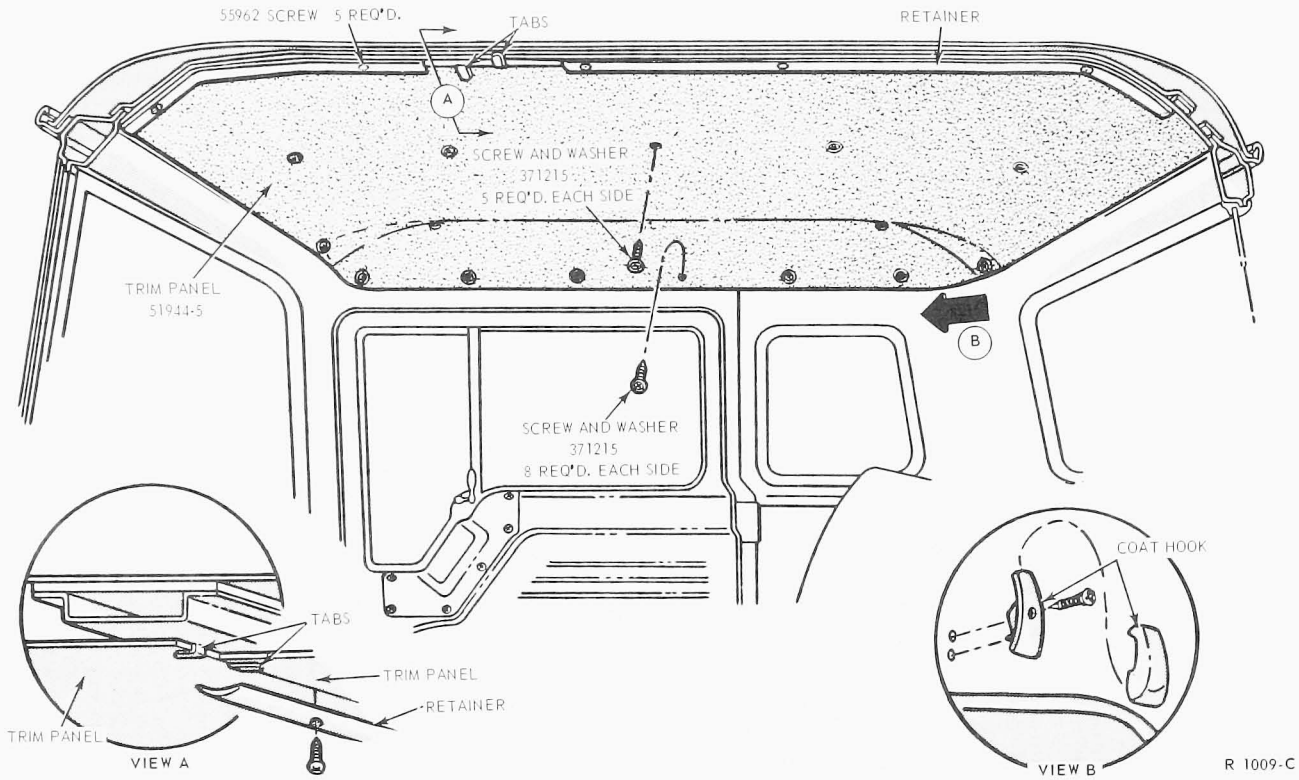

FIG. 4 Roof Trim Panel Installation—Tilt Cab

REMOVAL AND INSTALLATION

INSTRUMENT PANEL PAD

ECONOLINE

Removal

1. Open the hood, disconnect the battery cables and remove the battery to gain access to the heater attaching bolts.
2. Drain the cooling system into a container and save.
3. Remove the heater hose cover at the heater case (two screws).
4. Disconnect the wires at the heater resistor, heater motor and the auxiliary solenoid (if so equipped).
5. Remove the heater hoses from the heater assembly.
6. Remove the three heater-to-dash attaching bolts and pull the heater away from the dash panel to gain access to the heater control cable.
7. Disconnect the heater control cable, remove the heater assembly and place it on the bench.
8. Remove the instrument panel pad retaining nuts (six), and remove the pad (Fig. 1).

Installation

1. Position the pad to the instrument panel and install the pad retaining nuts (six).
2. Position the heater assembly to the dash board, connect and adjust the heater control cable and install the heater-to-dash attaching bolts (three).

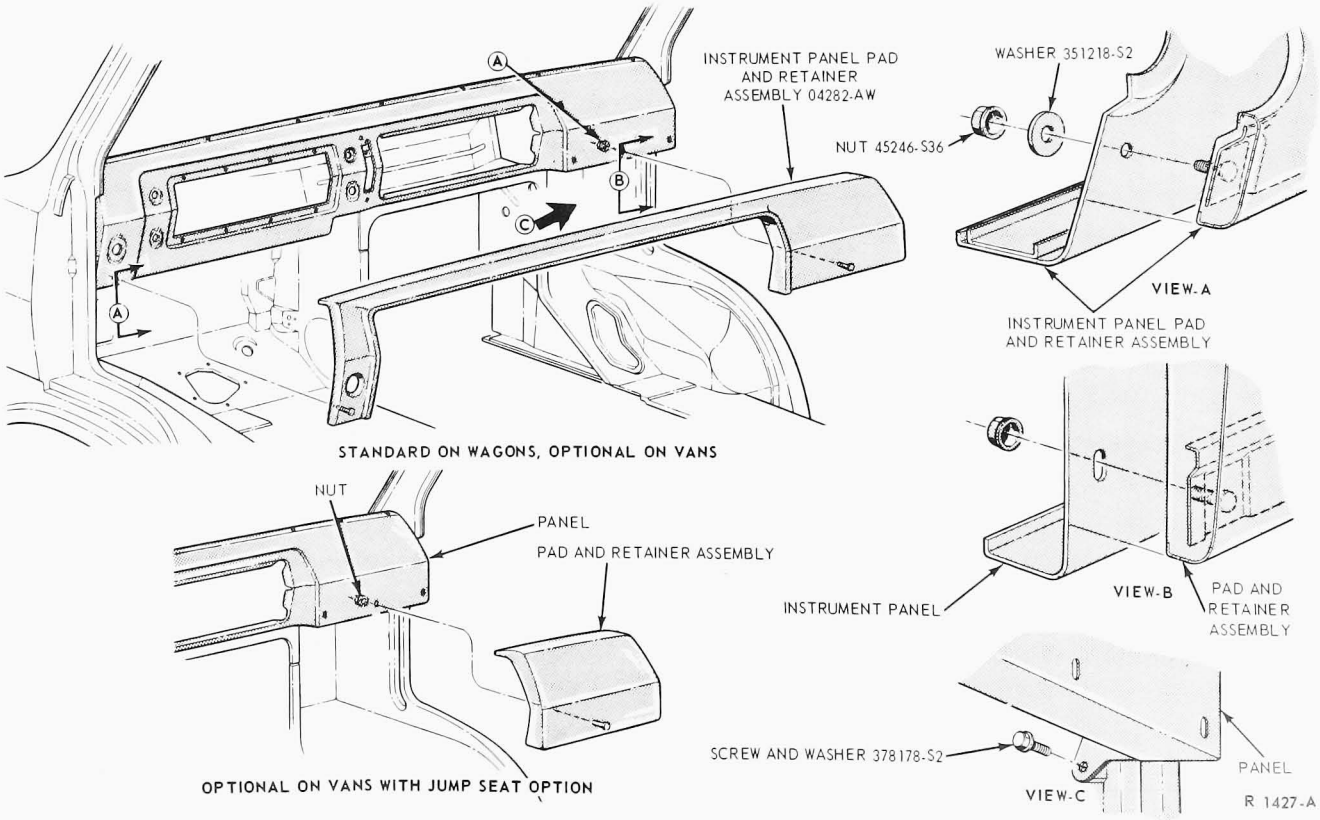

FIG. 1 Instrument Panel Pad Installation— Econoline

3. Install the heater hoses to the heater assembly.
4. Connect the wires to the heater resistor, heater motor and the auxiliary solenoid (if so equipped).
5. Install the heater hose cover to the heater case (two screws).
6. Fill the cooling system.
7. Install the battery and connect the cables.

BRONCO

If necessary to replace the instrument panel pad, remove the two windshield-to-body retaining latch knobs and the nine screws which retain the pad assembly to the instrument panel. Then, remove the pad.

F-100 THROUGH F-350

The instrument panel pad is attached to the instrument panel with ten nuts at 5 locations as shown in Fig. 2. To remove the pad, it is necessary to remove the instrument cluster (Group 33) center, right hand, left hand. A/C registers (if so equipped) and the glove box liner to gain access to the ten retaining nuts.

F-500 THROUGH F-750

Removal

1. Disconnect the negative battery ground cable.
2. After removing the retaining screw, pull the instrument cluster away from the instrument panel.
3. Remove the windshield defroster covers.
4. Remove the 14 attaching nuts and remove the pad and retainer assembly (Fig. 3).

Installation

1. Install the new pad and retainer assembly to the instrument panel with the pad studs entering the corresponding holes in the panel, and install the 14 retaining nuts (Fig. 3).
2. Install the windshield defroster covers.
3. Install the instrument cluster and connect the battery cable.

C-SERIES

Removal

1. Disconnect the negative battery ground cable.
2. After removing the retaining screws, pull the instrument cluster away from the instrument panel. If the vehicle has a radio, remove the speaker grille and the speaker.
3. Remove the 7 retaining screws and the windshield lower garnish moulding (Fig. 4).
4. Unsnap the left moulding (3 clips), the right moulding (7 clips), and remove the instrument panel pad.

Installation

1. Thoroughly clean the instrument panel area to be covered.
2. If the truck has a radio, position the cover on the instrument panel and, working from underneath, locate the speaker retaining screw holes on the cover. Remove the cover.
3. Using the screw hole markings as a guide, position the grille on the cover and mark the necessary grille opening on the cover. Cut out the opening.

Position the cover temporarily, marking the cover and the instrument panel at several locations for centering the cover.

4. Using a wide brush, apply Part No. 19C525 cement to the edges of the instrument panel and instrument panel pad. This cement is very fast drying, and the cover must be exactly positioned immediately after application of the cement.
5. Press the cover into position on the instrument panel.
6. If equipped with a radio, install the speaker and grille using three-inch screws.
7. Install the instrument cluster and then follow the appropriate procedure below to finish the installation.

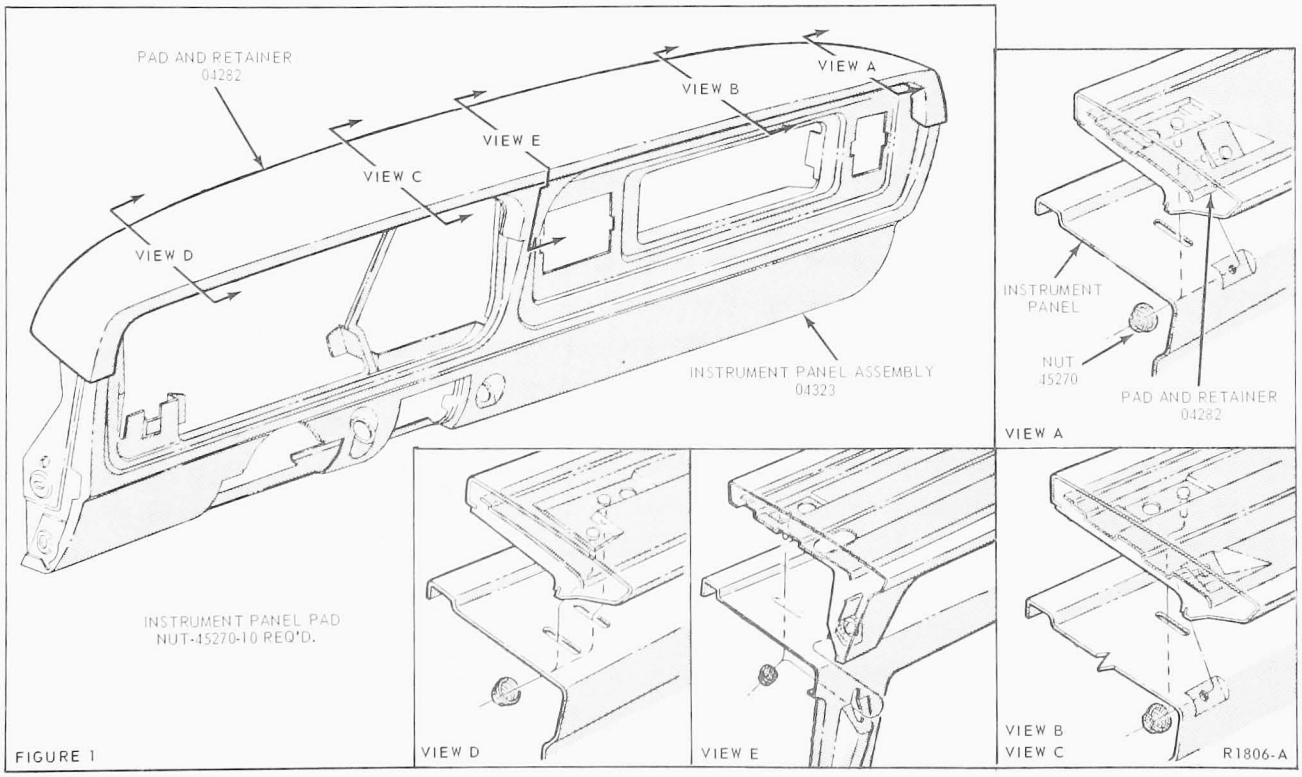

FIG. 2 Instrument Panel Pad Installation—F-100 Through F-350

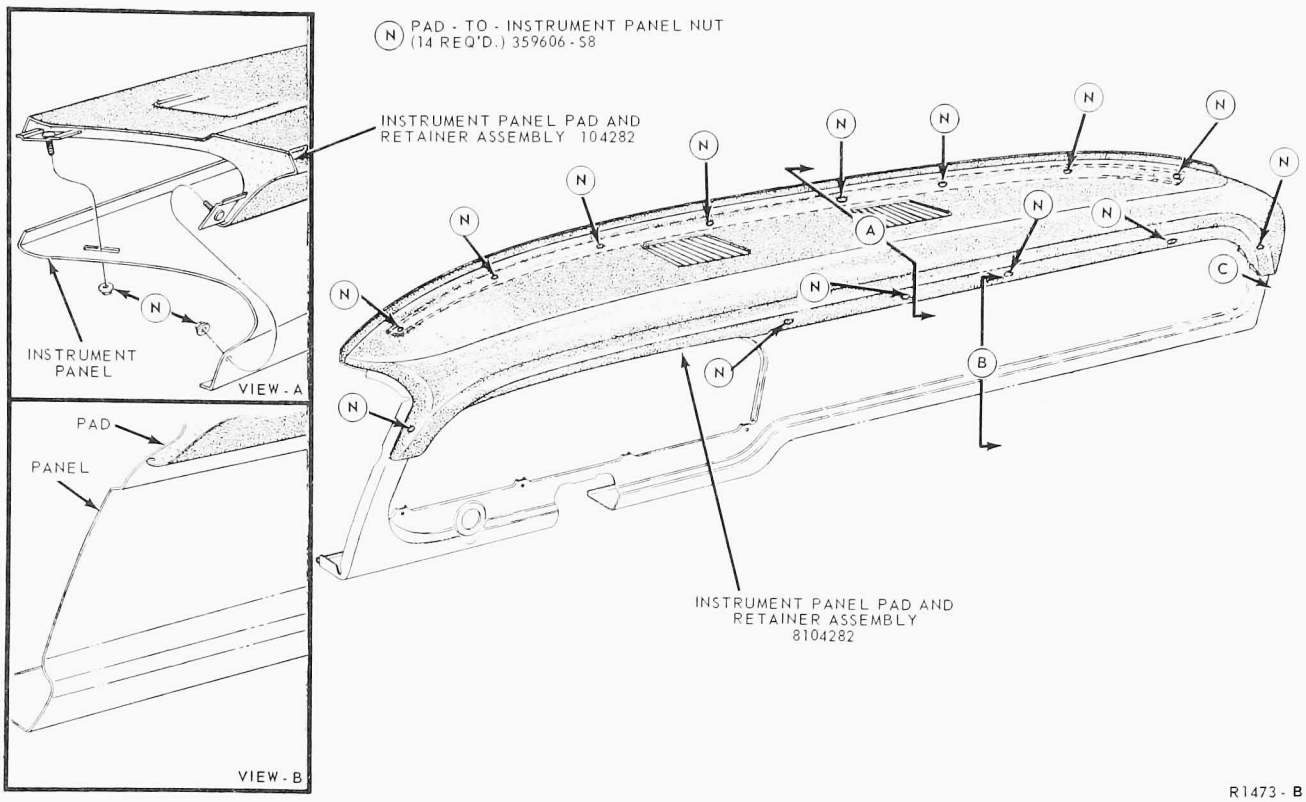

FIG. 3 Instrument Panel Pad and Retainer Assembly—F-500 Through F-750

8. Position the five windshield lower garnish moulding supports along the forward edge of the cover (Fig. 4), position the garnish moulding on the supports and secure with the seven retaining screws.
9. Position the retaining clips evenly in the safety cover lower mouldings, and locate the clip holes on the edge of the cover.
10. After drilling 1/8-inch holes through the cover and the instrument panel, snap the lower mouldings in place: right moulding (7 clips), left moulding (3 clips).
11. Connect the battery.

L-SERIES

The instrument panel and pad arrangement is installed as three different components: the right pad and retainer assembly on the right portion of the instrument panel; the right cluster opening pad and retainer assembly to the right of the cluster opening; and the left finish panel to the left of the cluster opening. Remove and install any one of these components as illustrated in Figure 5.

PART 46-50 Pick-up Box Cover

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENTS		REMOVAL AND INSTALLATION	
Liftgate Latch Striker	50-02	Cover Assembly	50-03
		Screen	50-03
DESCRIPTION	50-01	Window Glass	50-03

DESCRIPTION

The pickup box cover (Fig. 1) is designed for F—100 through F—350 trucks with eight foot boxes and 133 and 140 inch wheel bases. The box covers come in standard and deluxe models. Features of the standard model include fiberglass construction, tinted glass in side and rear windows, clear glass in the front window, a T-handle liftgate latch with lock and textured white paint. In addition, deluxe model features include sliding side windows with screens, bright moldings around side and rear windows, a roof vent, a dome light and two-tone paint.

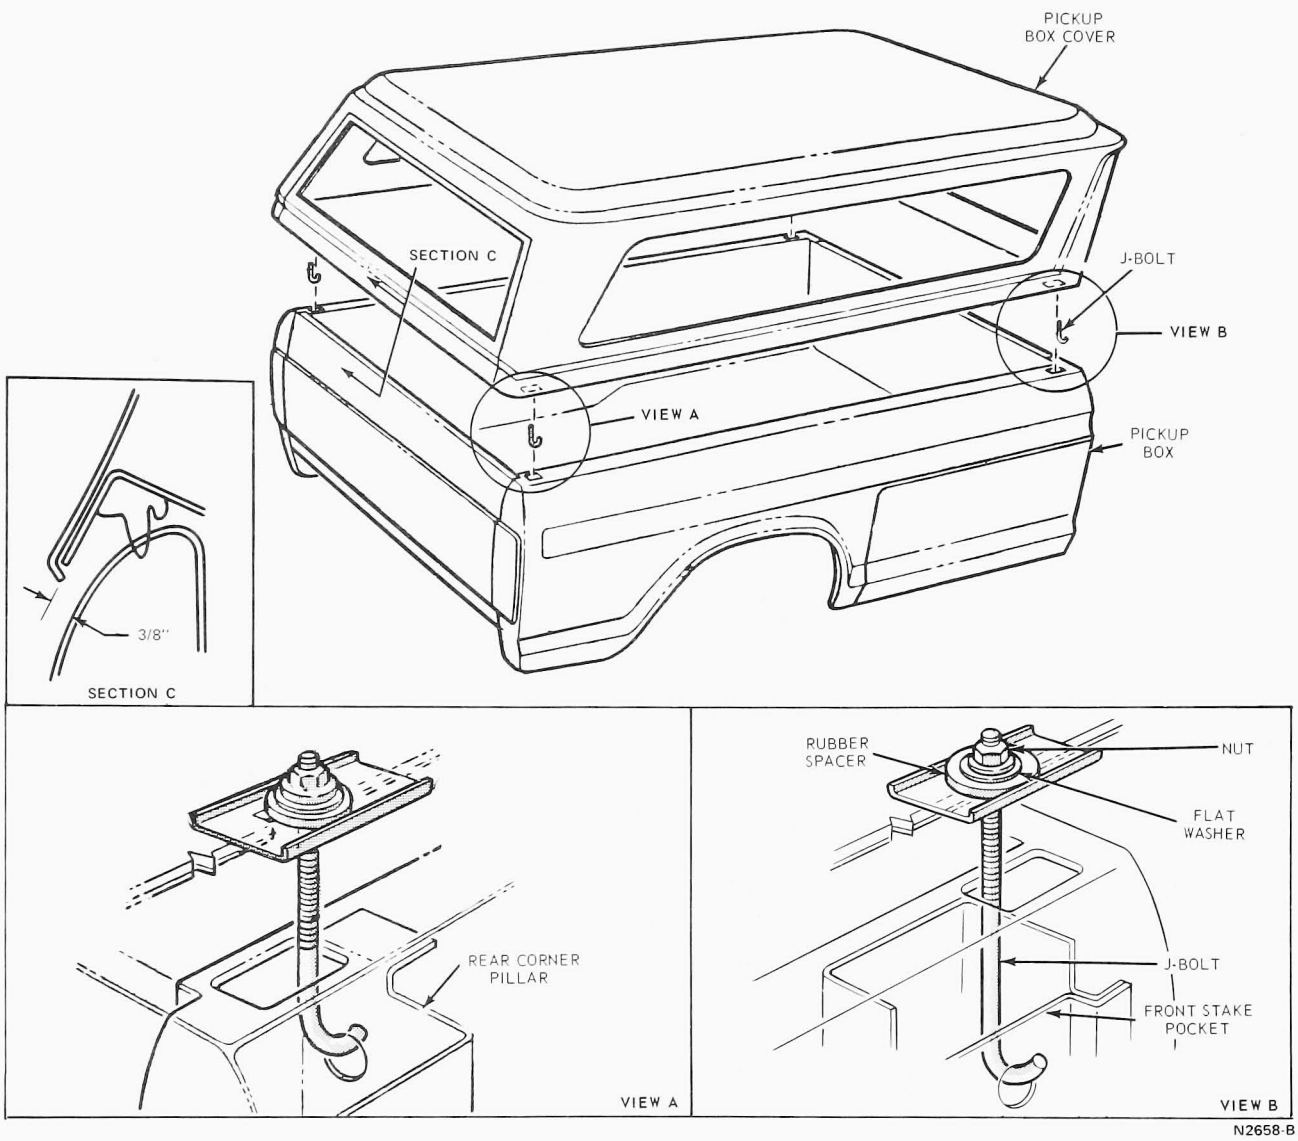

FIG. 1 Pickup Box Cover

ADJUSTMENTS

LIFTGATE LATCH STRIKER

The striker-latch relationship may change after installing or removing the cover causing a poor weatherseal or latch misalignment. To adjust the strikers:

1. Outline the strikers on the body with a pencil to record the existing position.
2. Loosen the attaching screws and adjust the strikers forward (to correct loss of seal) or rearward (to gain latch engagement) as required.
3. When strikers are properly positioned, tighten the attaching screws (7 to 11 ft-lb).

REMOVAL AND INSTALLATION

PICKUP BOX COVER

Removal

1. Disconnect the electrical wiring (two-way connector) at the left front corner of the Pickup Box (Deluxe Model only).
2. Remove the nuts, rubber spacers and flat washers from all four J-bolts (Fig. 1).
3. Unhook the J-bolts from the holes in the corner stake pockets and remove them through the cover mounting holes.
4. Remove the Pickup Box Cover from the truck.

Installation

1. Clean the top surfaces of the Pickup Box side and front panels and tailgate to remove any abrasive materials which may have collected.
2. With the liftgate closed, position the Pickup Box Cover on the Pickup Box so the cover is centrally located side to side and the bottom edge of the liftgate is no less than 5/16 inch away from the tailgate.
3. Insert the four J-bolts down through the cover mounting holes and hook them into the holes in the walls of the corner stake pockets (Fig. 1).
4. Assemble a rubber spacer, flat washer and nut (in that order) on each J-bolt. Tighten the nuts sufficiently to compress each spacer 3/16 inch.
5. Connect the electrical wiring (two-way connector) at the left front corner of the Pickup Box (Deluxe Model only).

SLIDING SIDE WINDOW ASSEMBLY

Removal

1. Remove the entire weatherstrip, window and frame assembly from the Pickup Box Cover (Fig. 2).
2. Place the window assembly on a work bench and remove the mouldings.
3. Remove the weatherstrip.
4. Place a knife between the stationary glass and its frame and cut the double-backed adhesive tape to separate the window from the frame.
5. With the stationary glass removed, the sliding glass can be removed by flexing the frame sufficiently to remove the glass.
6. Service the handle by removing the one attaching screw. The latch housing and latch housing retainers are cemented to the glass. Remove by using a knife and separating the subject part and the glass. **When removing the latch housing, note the position of the flange to ensure proper positioning during subsequent reinstallation.**
7. The glass opening cover is secured to the glass with adhesive and a retaining flange that is snapped in the glass hole. To remove the cover, taking care not to break the glass, carefully chip away the retaining flange using a screwdriver and hammer. Then, with a knife, cut the adhesive bond between the glass and the cover. **When removing the glass opening cover, note the position of the flange to ensure proper positioning during subsequent reinstallation.**
8. The vertical side glass weatherstrip retainer is attached to th glass with double-backed adhesive tape. To remove the weatherstrip retainer, insert a knife between the retainer and the glass and cut the double-backed adhesive tape. The vertical weatherstrips are retained in grooves of the retainer and will freely slide from the ends of the grooves.

Installation

Installation of the sliding window components can generally be accomplished in the reverse order of removal, however, some special procedure will be necessary.

1. When installing the vertical side glass weatherstrip retainer, clean the glass and retainer mating surfaces with alcohol or wax and grease remover to ensure that they are free from dirt, grease, etc. Then, with the surface clean, apply Double-Backed adhesive tape to the back side of the retainer and install it to the glass as shown in Fig. 3. **Ensure that the tape does not extend beyond the edges of the retainer.**
2. To install the glass opening cover, use structural two-part epoxy adhesive to cement the cover to the glass paying particular attention to the position of the raised portion of the flange as shown in Fig. 4. Then, snap the glass latch opening plate (Fig. 4) into the cover with a daub of ESB-M2G198-A adhesive.
3. To install the latch housing and/or latch housing retainers, use structural two part epoxy adhesive to cement the subject parts to the glass surface paying particular attention to the position of the raised portion of the latch housing flange as shown in Fig. 4.
4. When installing the stationary glass to the frame, clean the mating surfaces of the glass and frame with alcohol or wax and grease remover to ensure they are free of dirt, grease, etc. Then, with the surfaces clean, apply double-backed adhesive tape to the outside front half of the window frame and install the stationary glass as shown in Fig. 3. **Ensure that the tape does not extend beyond the edges of the frame and the glass is located on the frame so that the distance from the edge of the glass to the edge of frame is constant.**
5. Installation of the window mouldings (Deluxe Model) requires the drawcord method; refer to Group 43 for techniques of a typical installation.
6. Apply a bead of sealer to the periphery of the window opening (on the Pickup Box Cover) as shown in Fig. 2.
7. To install any of the window and weatherstrip assemblies into the pickup box cover, use the drawcord installation method outlined for Windshields in Group 43.

SLIDING WINDOW SCREEN

Removal

With the window fully open, slide the screen forward and lift out.

Installation

With the window fully open, slide the screen rearward while feeding the screen clips into the groove in the screen frame (Fig. 5).

PART 47-01 Body Shell, Exterior Trim, Frame and Underbody - General Service

GENERAL INFORMATION

TYPE OF SEALERS AND APPLICATION

Since many sealers are used in the assembly of the truck, the following all-purpose sealers have been selected for service use. The method and points of application are shown in each applicable group.

CAULKING CORD—19560

This sealer has a plastic base with an asbestos filler, is heavy bodied and is commonly known as perma-gum. It is used on spotweld holes, around mounding clips, and between two surfaces not sealed by a gasket. Apply the sealer with a putty knife.

TRIM CEMENT—19C525

This cement is recommended for body panel plastic water shield and on some soft trim installations. It is also useful for repair or replacement of other vinyl and rubber trim.

RUBBER CEMENT—19552

This quick-drying, strong, adhesive cement is designed to cement weatherstripping to doors, bodies, cowl ventilators, and the surrounding metal. Windows and windshields that are set in rubber, can be effectively sealed against leakage by flowing cement into affected areas.

Clean all grease, dirt, and old sealer from the surfaces to be cemented. Wash the surfaces thoroughly with a rag moistened with a suitable commercial cleaner. For best results, apply a medium coat of cement to both surfaces, allow it to dry until tacky, and then press both surfaces firmly together.

BODY SEALER 19562 (WHITE and/or BLACK)

This sealer does not run, is fast drying, and remains semi-elastic. The sealer can be used for seam sealing in such areas as the floor pan, wheelhouse, dash panel, running board, door openings, and drip rails. It can also be used to seal outside moulding clip holes, and for windshield and back window installation.

DIAGNOSIS AND TESTING

DUST AND WATER LEAKS

Remember, that the forward motion of the truck creates a slight vacuum within the body, particularly if a window or ventilator is partially open. Any unsealed crevice or small opening in the lower section of the body will permit air to be drawn into the body. If dust is present in the air, it will follow

Under certain conditions, water can enter the body at any point where dirt or dust can enter. Any consideration of water leakage must take into account all points covered under dust leaks.

To determine the exact location of a dust leak, remove the following trim from the cab; the cowl trim panel, the kick pads, and the floor mats.

Removal of the trim will reveal the location of most leaks. Seal these leaks, and road test the truck on a dusty road to make sure that all leaks are sealed. The entrance of dust is usually indicated by a pointed shaft of dust or silt at the point of entrance. After the road test, check for indications of a dust pattern around the door openings, cowl panel, and cowl side panel.

Sometimes leaks can be located by putting bright lights under the truck, with the above components removed, and checking the interior of the body at joints and weld lines. The light will show through where leaks exist.

FLOOR PAN PLUGS AND GROMMETS

Many plugs and grommets are used in the floor pan and dash panel. The floor pan plugs seal the various body bolt access holes.

If any plugs are missing or damaged, a dust or water leak may result. Such leakage may also occur around grommets used on the dash panel. When dust or water leaks are evident, these plugs and grommets should be checked for proper installation.

DRAIN HOLES

Drain holes are located on the underside of each door along the weld line of the inner and outer panels. If these holes become clogged with mud or road tars, water will collect inside the panels and rust the sheet metal from the inside. A sound of sloshing water in a door is an indication of this condition.

Check the drain holes regularly. Clean the drain holes of dirt and foreign material with a punch or screwdriver.

RATTLE ELIMINATION

Most rattles are caused by a loose bolt or screw. Foreign objects such as nuts, bolts or small pieces of body deadener in the door wells, pillars, and quarter panels are often the source of rattles. Door wells can be checked by carefully striking the underside of the door with a rubber mallet. The impact made by the mallet will indicate if loose objects are in the door well.

All bolts and screws should be tightened periodically. In the event that tightening the bolts and screws, located on such assemblies as the doors does not eliminate the rattles, the trouble is probably caused by **misalignment.** If this is the case, follow the adjustment and alignment procedures for these assemblies.

Rattles and squeaks are sometimes caused by weatherstripping and anti-squeak material that has slipped out of position. Apply additional cement or other adhesive, and install the material in the proper location to eliminate this difficulty.

ADJUSTMENTS

CHECKING BODY FOR MISALIGNMENT

To align or square up a body, take two opposite diagonal measurements between pillars. Use a measuring tram for these measurements. Take the measurements between reference points such as crease lines or weld joints which are diagonally opposite each other on the two pillars being measured. Since all measurements should be made from the bare metal, remove all interior trim from the checking points.

In some cases, it is difficult to obtain proper body alignment when repairing a body that is damaged on both sides. In these cases, horizontal and vertical measurements can be taken from a body of the same body style. Once these basic dimensions are taken and established on the damaged body, alignment can be made by diagonal measurements taken from points on the two pillars.

Do not attempt to correct any serious misalignment with one jacking operation. This is particularly true if other sections of the body also require aligning. Align each section proportionately until the proper dimensions are obtained.

Door openings are checked in the same manner as the body. Horizontal, vertical, and diagonal checking points are established on all four sides of the door opening that is being measured.

FRAME INSPECTION

ALL MODELS EXCEPT ECONOLINE

Frame misalignment can affect front

wheel alignment and can cause improper operation and/or abnormal wear of chassis parts.

Before checking frame alignment, inspect the frame for damage and loose parts. Inspect all frame members for cracks, twists, or bends. Check all welded connections for cracks. Inspect all rivets, bolts, and body support brackets for looseness. Make all necessary repairs or replacements.

DIAGONAL OR X FRAME CHECKING METHOD

ALL MODELS EXCEPT ECONOLINE

Frame alignment can be checked without removing the truck body from the frame by using the diagonal or X checking method.

1. Place the truck on a clean level floor and set the parking brake.
2. Select several points along one frame side member and very carefully transfer these points with a plumb bob to the floor. If desired, paper can be taped on the floor along both sides of the truck below the frame. Mark the points on the floor as accurately as possible.
3. Locate the corresponding points along the opposite frame side member, and very carefully transfer these points to the floor in the same manner.
4. Move the truck away from the marks on the floor, and measure between diagonal points. Both corresponding measurements should be equal within 1/4 inch. Measure diagonally between all points on the floor.
5. Measure between corresponding points parallel to the frame side members. These measurements should be within 1/4 inch of each other.

The squareness of the frame side member web and the lower flanges at the spring hangers should be within 1/16 inch. The squareness of the side member web at the steering gear mounting location should be within 1/16 inch. The web and flange should be square at all other points within 1/8 inch.

Any point on one side member should be within 1/8 inch ahead, behind, above, or below the corresponding point on the opposite side member. The frame should not be bowed more than 1/8 inch for each 100 inches of frame length. The overall width of the frame should not vary more than 1/8 inch.

FRAME REPAIR

ALL MODELS EXCEPT ECONOLINE

Drilling Precautions

Do not drill holes in the frame flanges, since this tends to reduce the frame strength.

Welding Precautions

Disconnect the negative battery ground cable before using electric welding equipment.

All frame welding should be done with electric welding equipment, and the heat should be kept in a small area to prevent change in hardness of the metal. **Do not apply heat to or weld 50,000, 80,000 and 110,000 psi frames.**

When a reinforcement is welded to a side member, run the welds lengthwise along the reinforcement.

Frame Straightening

Frame misalignment can be corrected by straightening the out-of-line parts or by replacing the crossmembers, braces, or brackets if they are badly damaged.

To prevent internal stresses in the metal, frame straightening should be limited to parts which are not severely bent. **If heat is needed to straighten a frame member, keep the temperature below 1200 degrees F (a dull red glow). Excessive heat may weaken the metal in the frame members and cause permanent damage. Do not apply heat to 50,000, 80,000 and 110,000 psi frames.**

Frame Reinforcing

After a bent frame member has been straightened, inspect the member closely for cracks. If any cracks show, the frame member should be reinforced or replaced. If the frame is a 50,000, 80,000 or 110,000 psi frame, **no repair method is approved.**

Reinforcements can be made from channel, angle, or flat stock. The reinforcement stock should be of the same material and the same thickness as the frame member being reinforced.

To insure sound repair, the crack should be prepared before the reinforcement is welded to a cracked frame member. **Do not weld 50,000, 80,000 and 110,000 psi frames. The only frame that welding is permissible on is the 36,000 psi frame.** To prevent the crack from spreading, drill a 1/8 inch hole at the root of the crack. Grind out the crack to form a slot which will allow the weld to penetrate to the surface of the reinforcement.

The proper location of the reinforcement depends upon the location of the crack. If the crack is at the bottom of the channel, the reinforcement should be welded to the channel bottom. If the crack extends along the side of the channel, an additional reinforcement should be welded to the side.

Frame Member Replacement

If a damaged frame member is to be replaced, new bolts, grade 8 fasteners and rivets required for replacement of parts, should be of the same specifications as the original bolts or rivets. In cases where it is necessary to substitute a bolt for a rivet, use the next larger size bolt.

PART 47-30 F-100 Through F-350

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION		Fender	
Body Mounts	30-02	Front	30-01
Body Sealer	30-01	Rear	30-01
Bumper	30-01	Grille	30-01
Exterior Mouldings	30-01	SPARE TIRE CARRIER	
		Side Mounted	30-04
		Slide Out	30-04

REMOVAL AND INSTALLATION

RADIATOR GRILLE

F-100 THROUGH F-350

The radiator grille assembly consists of the grille outer shell and two grille inserts. Each insert is attached to the outer shell with eight screws which can be removed from the the front of the vehicle.

The grille outer shell installation is shown in Fig. 1.

1. To remove the outer shell, remove four screws attaching each end of the grille to the fender.
2. Remove the lower retaining screws along the lower edge of the grille.
3. Remove the grille outer support bracket-to-radiator support bolts at each end of the grille.
4. Remove the upper mounting bracket-to-grille bolts.
5. Disconnect the parking light wires and remove the grille.
6. Tansfer all U-nuts, clips, mounting brackets etc. to a new grille if the grille is to be replaced. Then, position the grille.
7. Connect the parking light wires.
8. Install the upper mounting bracket-to-grille bolts.
9. Install the grille outer support bracket-to-radiator support bolts at each end of the grille.
10. Install the lower retaining screws along the lower edge of the grille.
11. Install the four screws attaching each end of the grille to the fender.

FRONT FENDER

Removal

1. Clean all dirt from the fender attaching screws, bolts and nuts.
2. Remove the grille and headlight assemblies from the vehicle.
3. Remove the screws attaching the front of the fender to the radiator support.
4. Remove one screw attaching the rear lower end of the fender to the lower corner of the cab and remove one pin retaining the seal to the lower corner of the cab (Fig. 2).
5. Remove one screw from inside the cab attaching the top rear corner of the fender to the cowl.
6. Remove the screws attaching the top edge of the fender to the fender apron and radiator support and remove the fender from the vehicle.
7. Remove the pins attaching the seal (Fig. 2) to the fender and remove the seal from the fender.
8. Remove the nuts and retainers from the fender.

Installation

1. Position the nuts and retainers on the fender.
2. Position the seal to the fender and install the attaching pins.
3. Apply sealer to the upper edge of the apron.
4. Position the fender to the apron and install the screws loose.
5. Install one screw from the inside of the cab loose, attaching the top rear corner of the fender to the cowl.
6. Install a pin retaining the seal to the lower corner of the cab, and install the screw loose, attaching the rear lower end of the fender to the lower corner of the cab.
7. Install the screws loose, attaching the front of the fender to the radiator support.
8. Adjust the fender position and tighten all mounting screws.
9. Install the grille and headlight assemblies.

REAR FENDER—PICK-UP

1. Clean the dirt from the fender retaining bolts and nuts with a wire brush.
2. Remove the fender brace to fender nut and bolt.
3. Remove the fender to body nuts and/or bolts, and remove the fender.
4. Clean the body in the fender attaching area.
5. Position the new fender, and start all of the attaching bolts and nuts to assure bolt hole alignment.
6. Tighten all of the fender retaining nuts and bolts.

FRONT BUMPER

The two methods of front bumper installation for all light truck models are shown in Fig. 3. On models with the bumper bolted directly to the frame, remove the bumper bolts and lift the

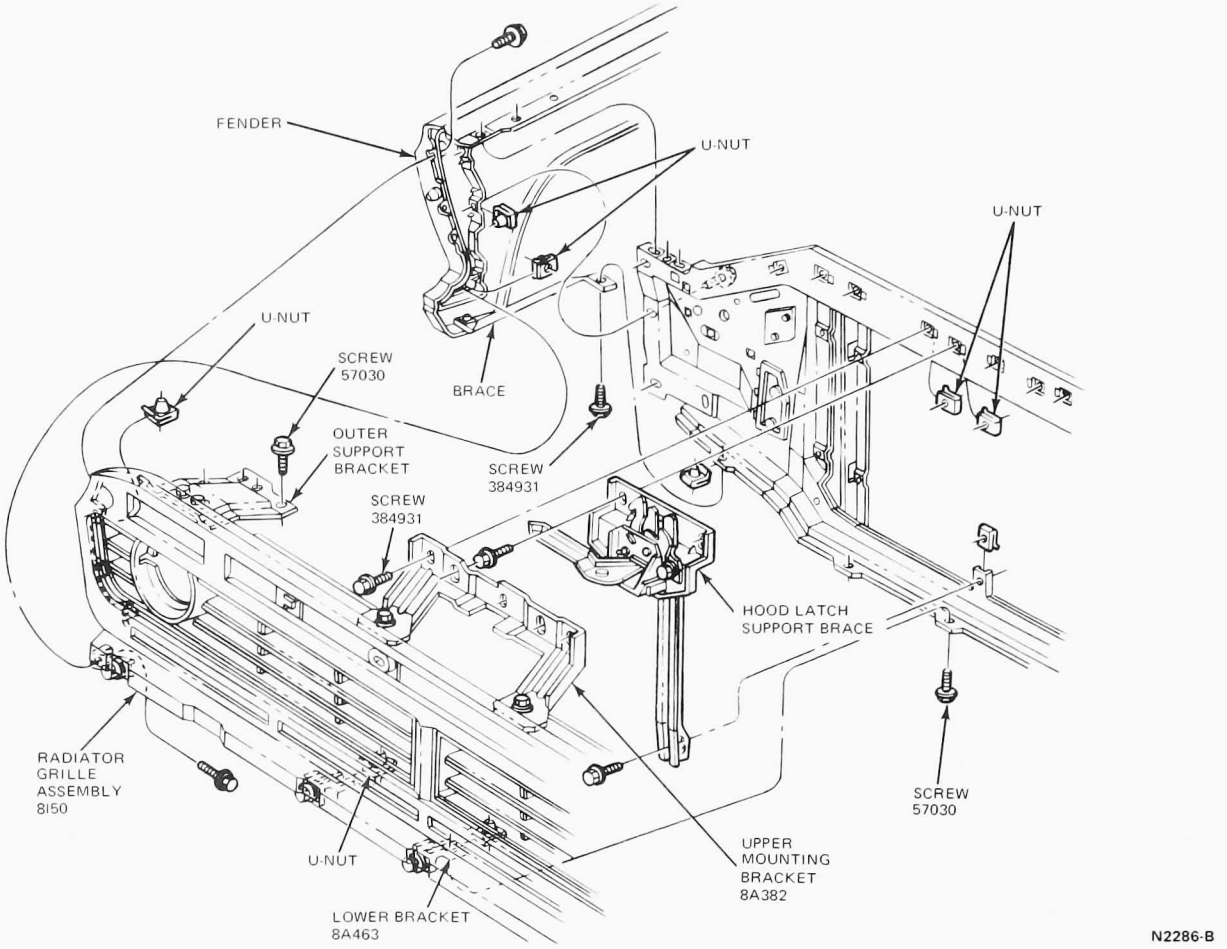

FIG. 1 Grille, Hood Latch and Related Parts—F-100 Through F-350

bumper from the frame. On models with bumper brackets (Fig. 3), remove the bumper bracket to frame attaching bolts and remove the bumper and brackets. Then, remove the brackets from the bumper.

EXTERIOR MOULDINGS

Before removing the exterior mouldings, determine by the type of retainer used if it is necessary to remove an interior trim panel (Fig. 4 through 6). If a weld stud is distorted or broken off, it should be replaced with a screw (379560-S101).

BODY SEALER

The body sealer locations are shown in Fig. 9. The sealer types and application procedures are given in General Information of Part 47-01. The test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

BODY MOUNTS

Removal

1. Loosen the attaching bolt leaving a minimum of four threads in the retainer.
2. Using a long solid bar or drift and a large hammer, strike the head of the attaching bolt sharply downward to separate the **swedged** or **flare** portion of the lower retainer from the upper retainer. Holding the lower retainer nut, remove the attaching bolt, lower retainer and absorber (Fig. 7). Note: On vehicles with a frame mounted **midship** auxiliary fuel tank or a **in cab** fuel tank, it will be necessary to either loosen or remove the fuel tank to provide tool clearance when removing the rear cab mounts. Refer to Part 24-50 for removal and installation procedures.
3. Loosen all cab mount attaching bolts before raising the cab. Leave the bolts loosely in place in the mounts not being replaced.
4. Raise the body section enough to remove the upper absorber and retainer assembly.
5. Discard all parts removed.

Installation

1. Position the new upper absober and retainer assembly. Be sure the pilot section of the rubber absorber is positioned correctly in the frame crossmember or bracket.
2. Lower the body section onto the new upper absorber and retainer. Use a drift to align the holes in the sheet metal and the mount.
3. Insert the proper attaching bolt (Fig. 7).
4. Position a new lower absorber and lower retainer assembly on the attaching bolt and tighten until snug.
5. Holding the lower retainer assembly with a suitable wrench, tighten the attaching bolt to 40 lb. ft. for the front end sheet metal mounts or 50 lb. ft. for the front and rear cab mounts.

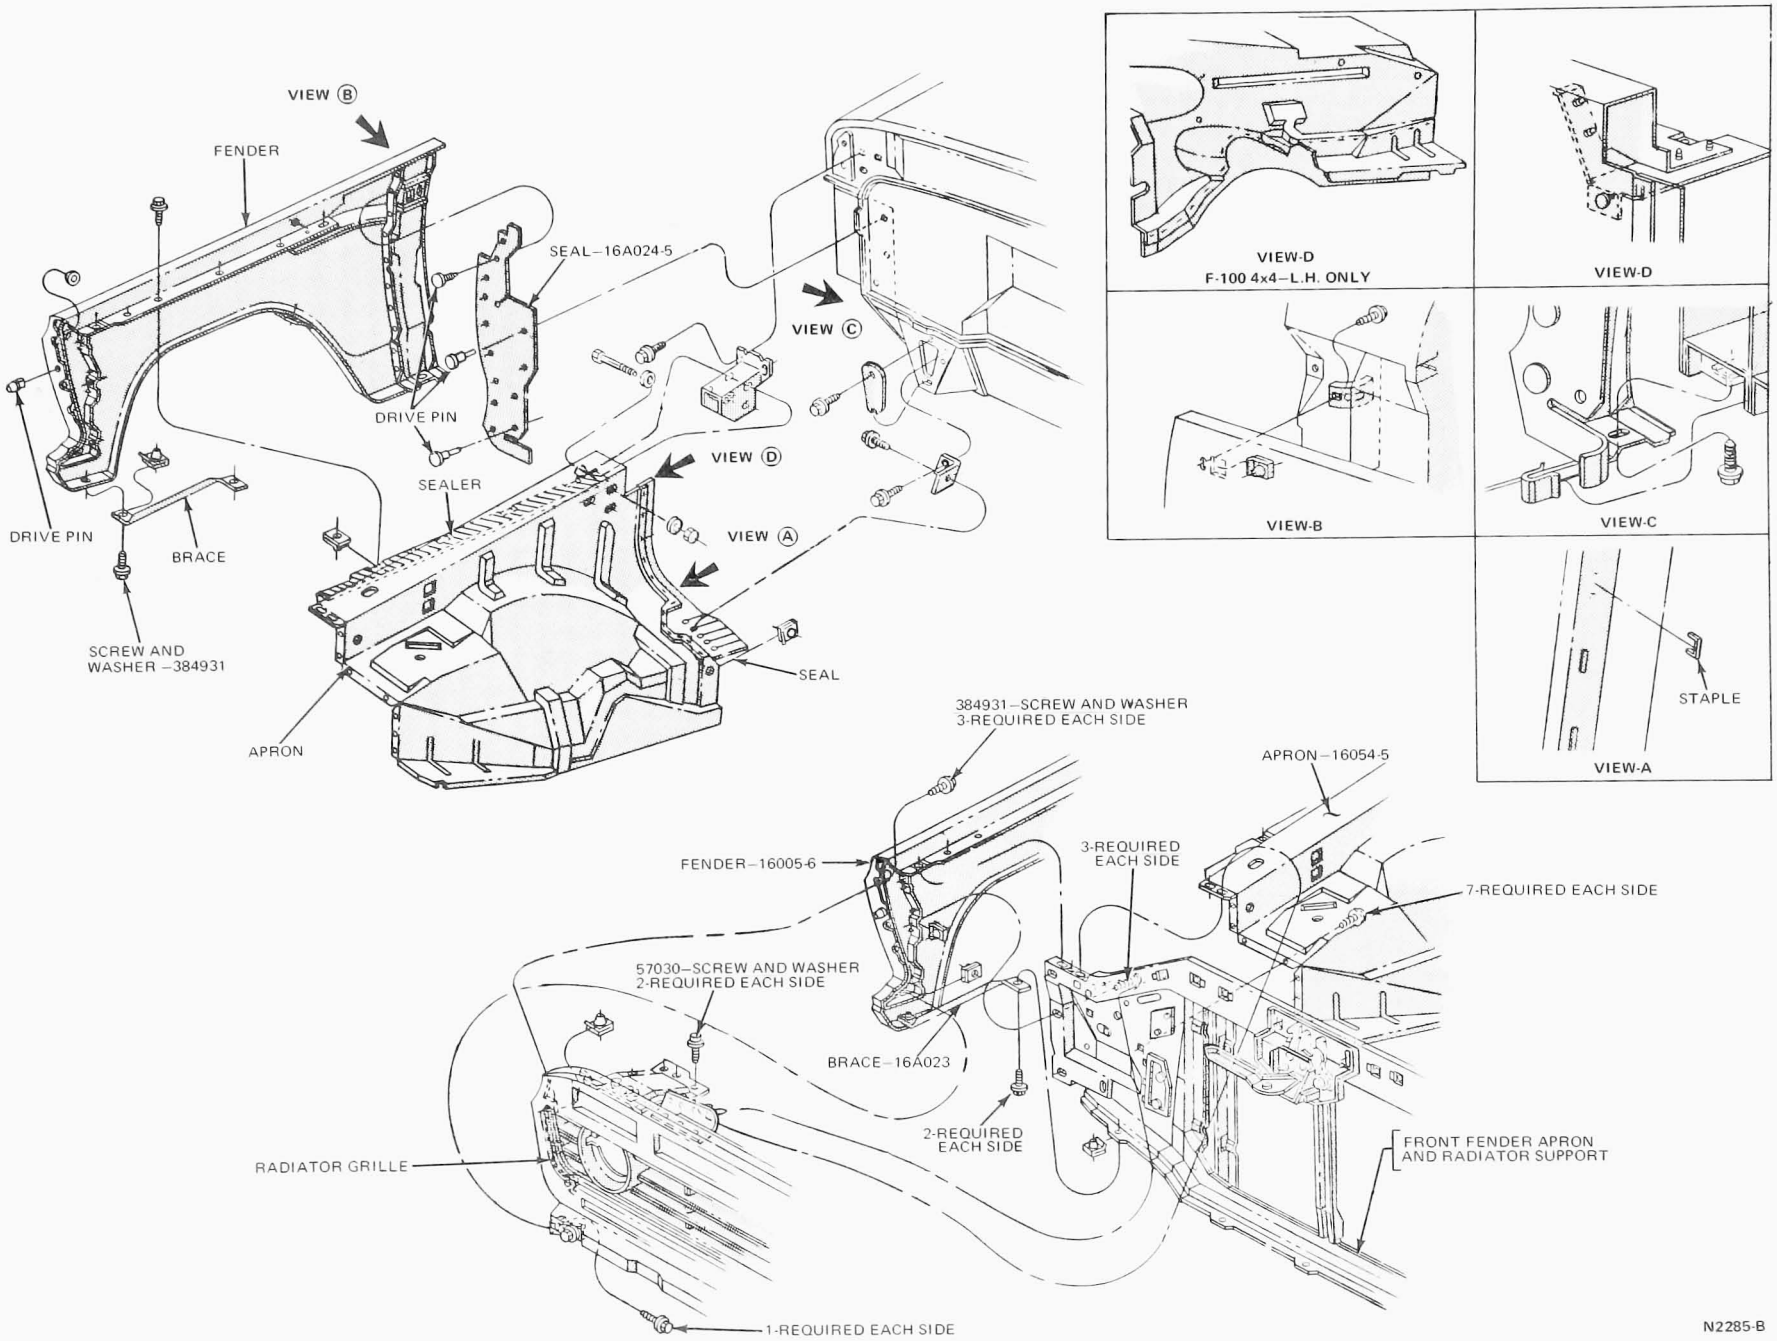

FIG. 2 Front Fender Installation

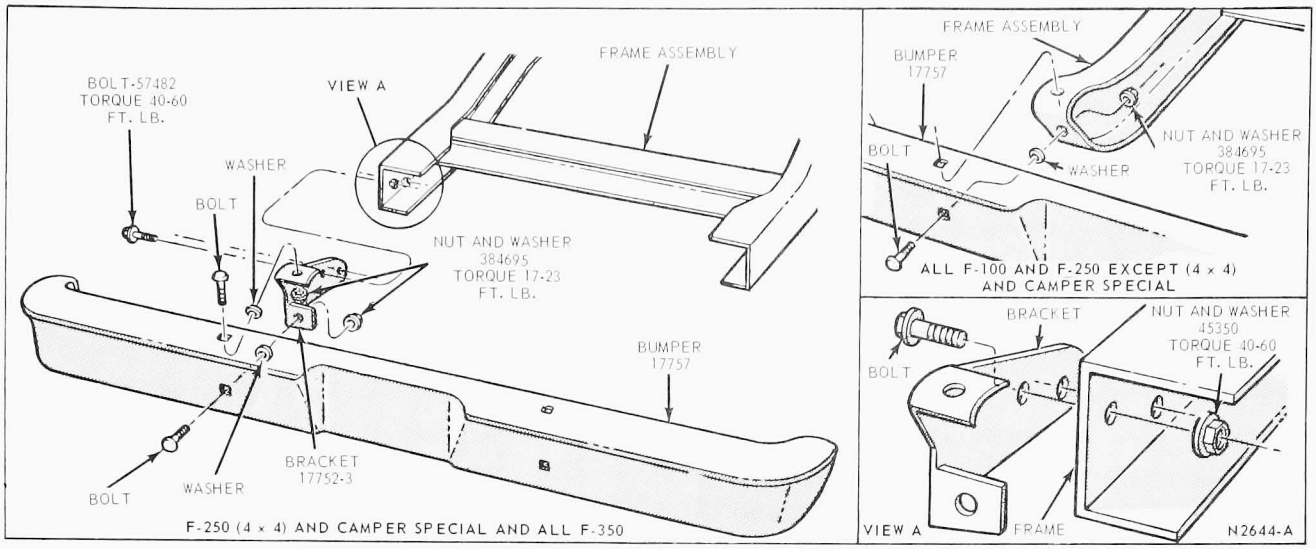

FIG. 3 Front Bumper Installation

6. Tighten all other mounts that were loosened to the appropriate torque.
7. On trucks equipped with a midship auxiliary tank it is necessary to cut the left rear cab attaching bolt 1/2 inch from the lower retainer nut to provide adequate clearance between the bolt and the fuel tank. Retorque the bolt after cutting. This operation is only necessary when the left rear cab mount is replaced.
8. If the fuel tank was loosened or removed, reinstall the fuel tank in the original position.

SLIDE-OUT SPARE TIRE CARRIER

F-100 AND F-250

Removal

1. Rotate the lock pin, aligning the tang on the pin with the slot in the channel assembly and the release handle. Remove the lock pin (Fig. 8).
2. Pull down on the release handle by pulling it down and outward to unlock the carrier channel assembly from the latch bracket assembly.
3. The channel assembly and spare tire assembly is now held by the latch bracket assembly tangs.
4. Grasp the release handle and lift the carrier and spare tire upward to take the weight off of the latch bracket assembly. Pull the latch bracket outward to release latch from channel assembly and carefully lower the spare tire and channel assembly to the ground.
5. Grasp the **hand-hold** area of the channel assembly and, lifting slightly, pull both the spare tire and channel assembly outward until the channel assembly contacts the builtin stop of the support assembly.
6. Remove the spare tire and wheel from the channel assembly.

Installation

Before installing the spare tire and wheel assembly into the slide-out carrier, refer to Fig. 8 for spacer requirements and adjustment procedures.

1. Place spare tire assembly in position on channel assembly.
2. Lifting the channel assembly and spare tire, slightly, push both back under the vehicle until the channel assembly hits the stop and is positioned correctly on the support assembly. Note: The latch bracket assembly must be lined up with the slot in the channel assembly and the support assembly.
3. Lift the spare tire assembly and channel assembly upward. The latch bracket assembly should slide freely through the slot of the channel and support assembly until the latch bracket assembly snaps into position and now supports the spare tire assembly and channel assembly.
4. Push the release handle downward (rotating inward) until it is in the **locked** position.
5. Install the lock pin in position and lock the release handle to the channel assembly (Fig. 8).

SIDE-MOUNTED SPARE TIRE CARRIER

F-100 THROUGH F-350

Removal

The side-mounted spare tire carrier is enclosed with a removable cover panel assembly. The cover panel assembly is held in position by two **torsion-bar** type wire latches and two **hook-type** hinges and hinge brackets.

1. Release the front and rear latches (item #3 Fig. 9), by lifting the latch handle out of the locked position in the lower panel inner flange. Push the latches inward and at the same time, pull downard and outward which releases the panel at the top.
2. Swing the panel assembly (item #1) outward and remove both front and rear hooks (hinge) from the front and rear hinge brackets (item #5 and #2) and remove the panel assembly.
3. Release the wing nut safety latch (swing the latch upward) and remove the wing nut (item #7).
4. Lower the retainer plate assembly (item #6) to the ground. Note:**The plate assembly is utilized as an assist ramp for removal and installation of the spare tire.**
5. Remove the wing nut bolt (item #5) from the inner support assembly (item #4) and grasping the lower part of the spare tire, pull it away from the support assembly (item #4) allowing the spare tire assembly to slide down the retainer plate assembly as an assist ramp (item #6).

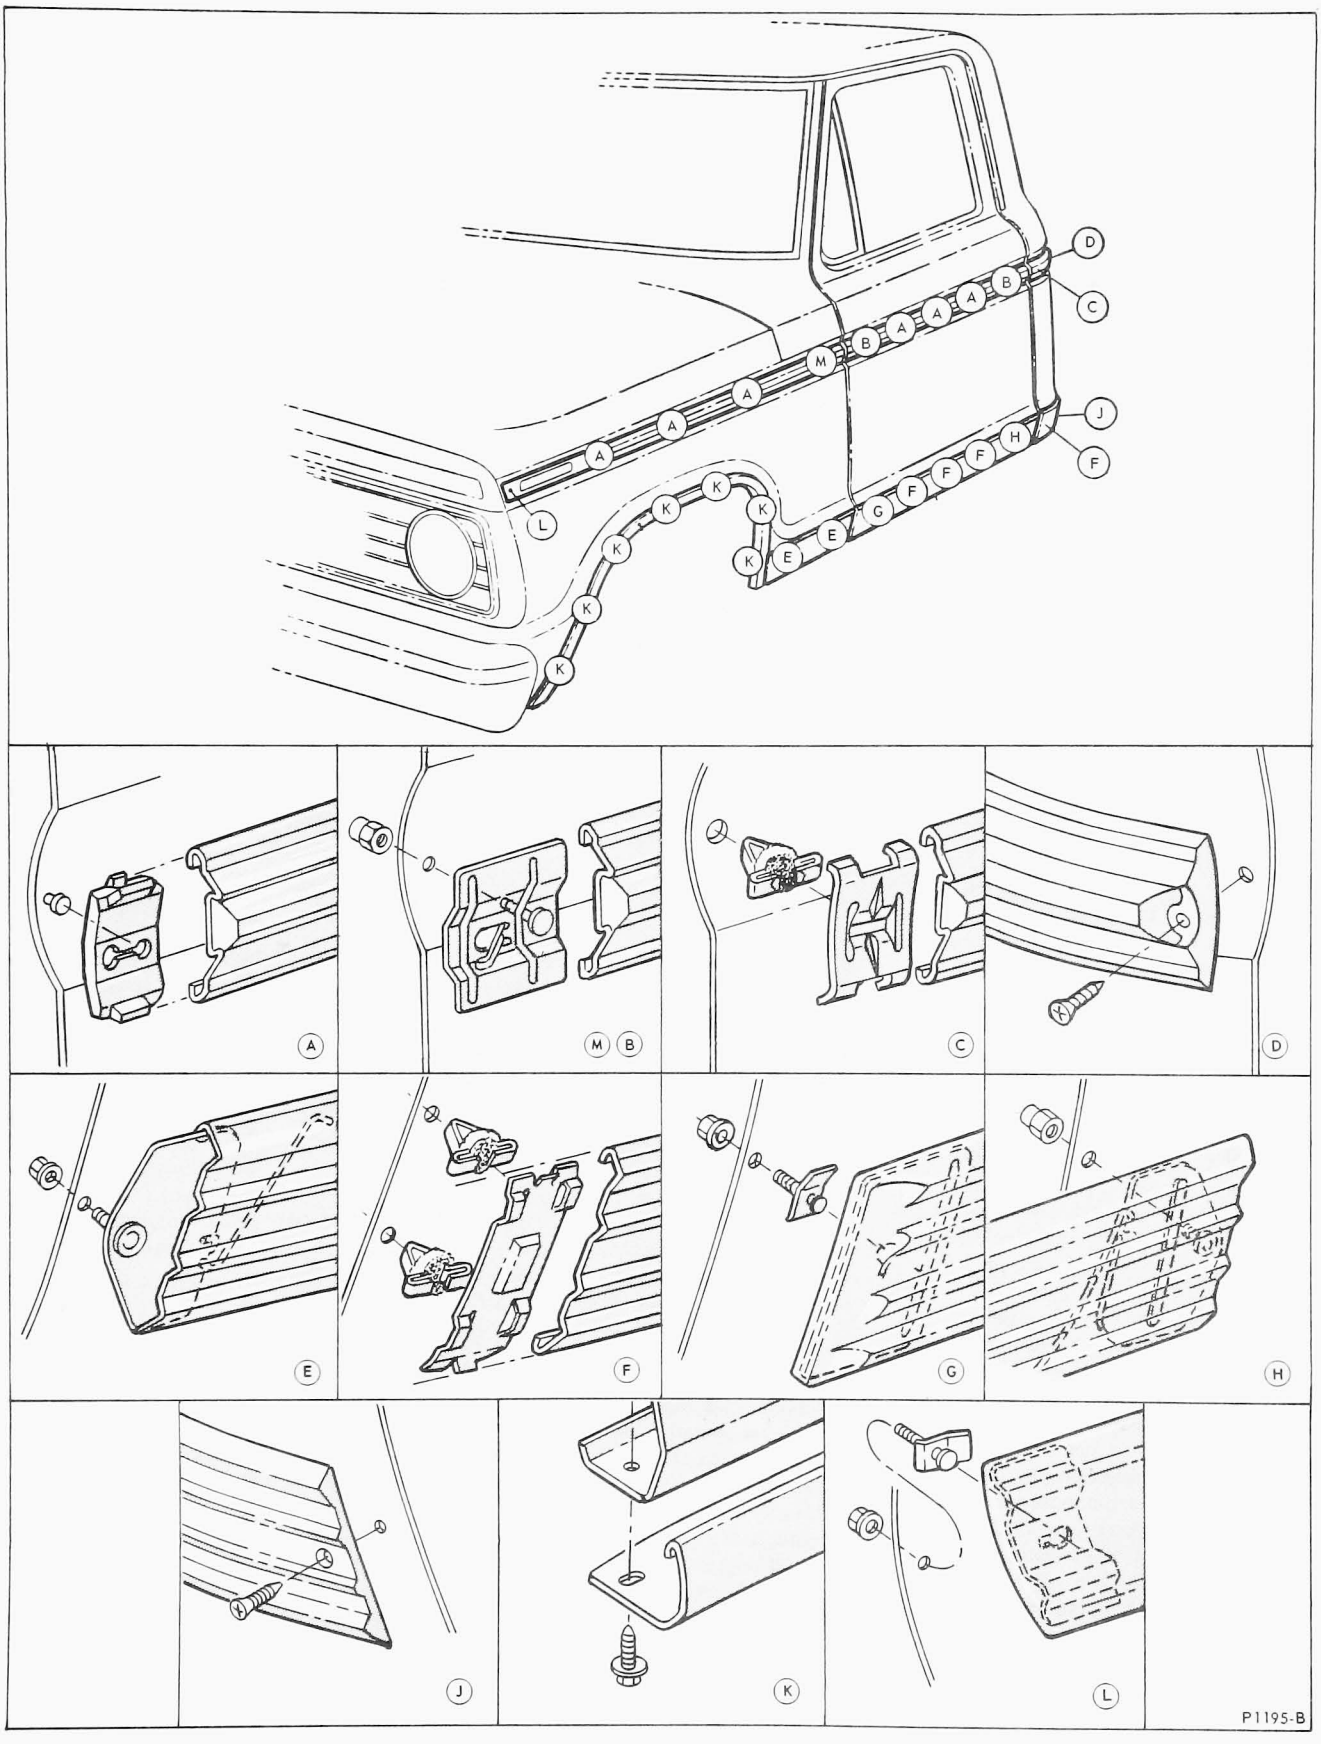

FIG. 4 Cab Exterior Mouldings—Ranger

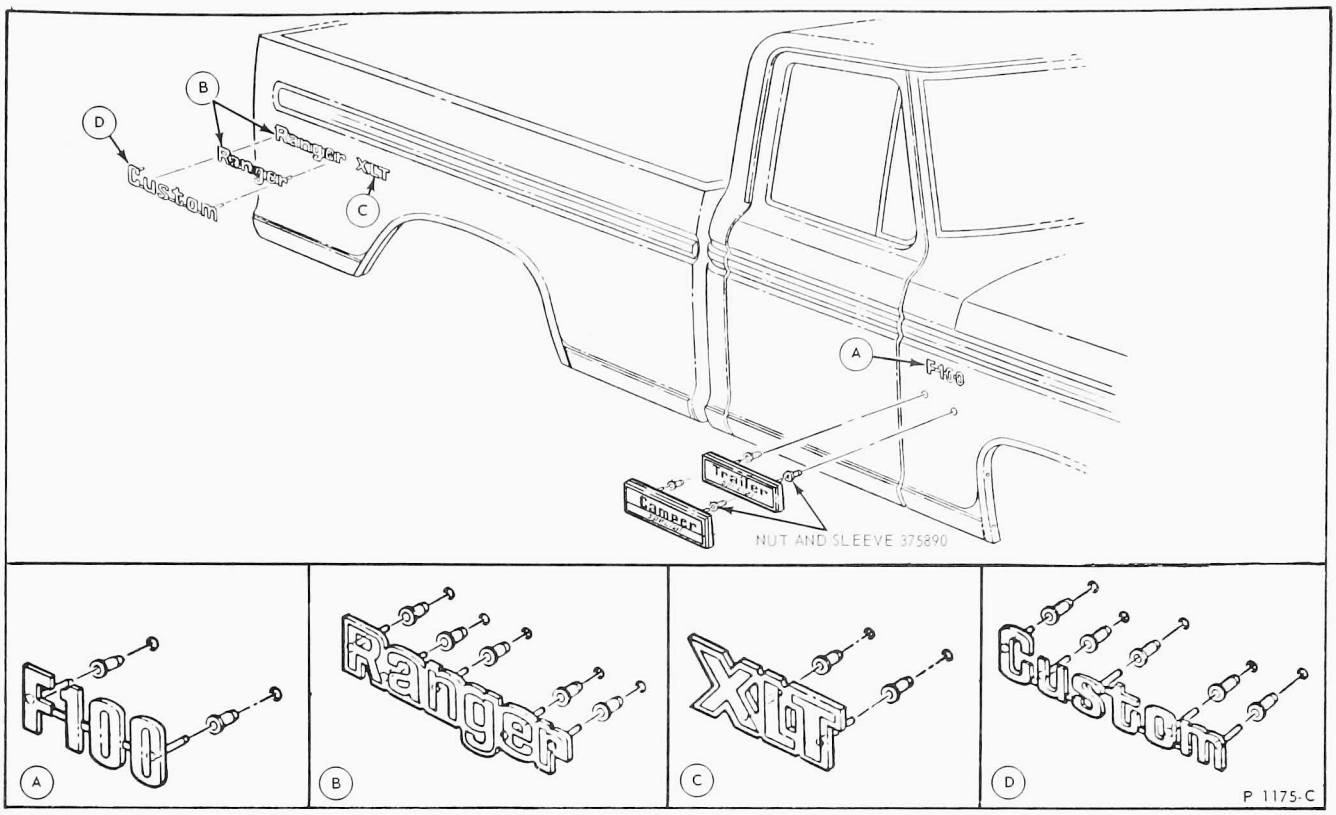

FIG. 5 Cab Exterior Mouldings

Installation

Note: On vehicles not originally equipped with a spare tire, the carrier will have a shipping bolt and nut installed (item 10 and 12) which must be removed and discarded before installing a spare tire at a latter date. See Fig. 9.

1. Position the spare tire on the retainer plate assembly (item #6 Fig. 9) and roll or slide the spare tire up into the storage compartment with the lower part of the spare tire resting on the retainer assembly.
2. Lifting up on the retainer assembly will push the spare tire into position allowing it to rest on the inner support assembly (item #4). Install the wing nut bolt (item #5) on the support assembly. Push the outer retainer plate against the spare and insert the wing nut bolt through the hole in the retainer as shown in Fig. 9.
3. Install the wing nut and tighten securely. Rotate the safety latch downward into position against the wing nut.
4. Positioning the front and rear hooks (hinges) into the front and rear hinge brackets (item #5 and #2), swing the cover panel upward into position in the opening of the pick-up box side panel. Hold panel in this position.
5. Push the front and rear latch handles inward past the lower panel flange and, lifting each latch handle upward to clear the upturned flange, pull each latch handle outward and allow the latch handle to drop into the **locked** position in the panel lower flange.

COMPONENT INDEX	Page	COMPONENT INDEX	Page
REMOVAL AND INSTALLATION		REMOVAL AND INSTALLATION - Cont.	
Body Sealer	31-3	Fender – Front	31-3
Bumper – Front	31-3	Grille	31-1

REMOVAL AND INSTALLATION

RADIATOR GRILLE

Removal

1. Remove 3 screws attaching each end of the grille to the front fender (Fig. 1).
2. Remove 6 screws attaching upper support to radiator support.
3. Remove hood latch support lower 2 screws.
4. Remove lower center bracket attaching screw.
5. Remove the outer lower bracket-to-radiator support screw (1 each side).
6. Disconnect headlight wires and remove grille.
7. Transfer the hood latch support, upper support, headlights and mounting brackets to new grille if the grille is to be replaced.

Installation

1. Position the grille to the front of the vehicle and connect the headlight plugs to the headlamps.
2. Install the outer lower bracket-to-radiator support screw (one on each side).
3. Install the lower center bracket attaching screw.
4. Install the hood latch lower support screws (two).
5. Install six screws attaching the upper support to the radiator support.
6. Install three screws attaching each end of the grille to the front fender(s).

FRONT FENDER

Removal

1. Clean all dirt from the fender attaching screws, bolts and nuts.
2. Remove the grille and headlight assemblies from the vehicle.
3. Remove five screws attaching the top edge of the fender apron to the fender (Fig. 2).
4. Remove the four screws attaching the rear of the fender to the cab.
5. Remove three screws attaching the front of the fender to the radiator support (Fig. 2) and remove the fender from the vehicle.
6. Remove three screws and nuts attaching the extension brace to the fender and extension, and remove the brace.
7. Remove three extension attaching screws and nuts and remove the rear lower extension from the fender.
8. Remove nine seal pins and remove the seal from the fender (Fig. 2).
9. Remove the rear filler (Fig. 2) from the rear edge of the fender.
10. Remove all nuts and retainers from the fender.

Installation

1. Position the nuts and retainers on the fender.
2. Position the rear filler (Fig. 2) to the fender and install the attaching screws, washers, and nuts.
3. Position the seal to the fender and install the attaching pins.
4. Apply sealer to the upper edge of the lower rear extension (Fig. 2) and position the extension to the fender. Then, install the three attaching bolts and nuts.
5. Position the extension brace to the fender and extension and install the three attaching screws and nuts.
6. Apply sealer to the fender apron (Fig. 2), and position the fender to the vehicle and over the fender apron and install the fender to fender apron attaching screws loose.
7. Position the front of the fender to the radiator support and install the three attaching screws loose.
8. Install the four screws that attach the rear of the fender to the cab.
9. Install the radiator grille and headlight assemblies on the vehicle.
10. Align the fender to the body and tighten all the fender attaching screws.

FRONT BUMPER

Remove the bolts attaching the bumper to the frame and remove the bumper from the vehicle. To install the bumper, position the bumper to the frame and install the attaching bolts.

BODY SEALER

The sealer types and application procedures are given in General Information of Part 47-01. The test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

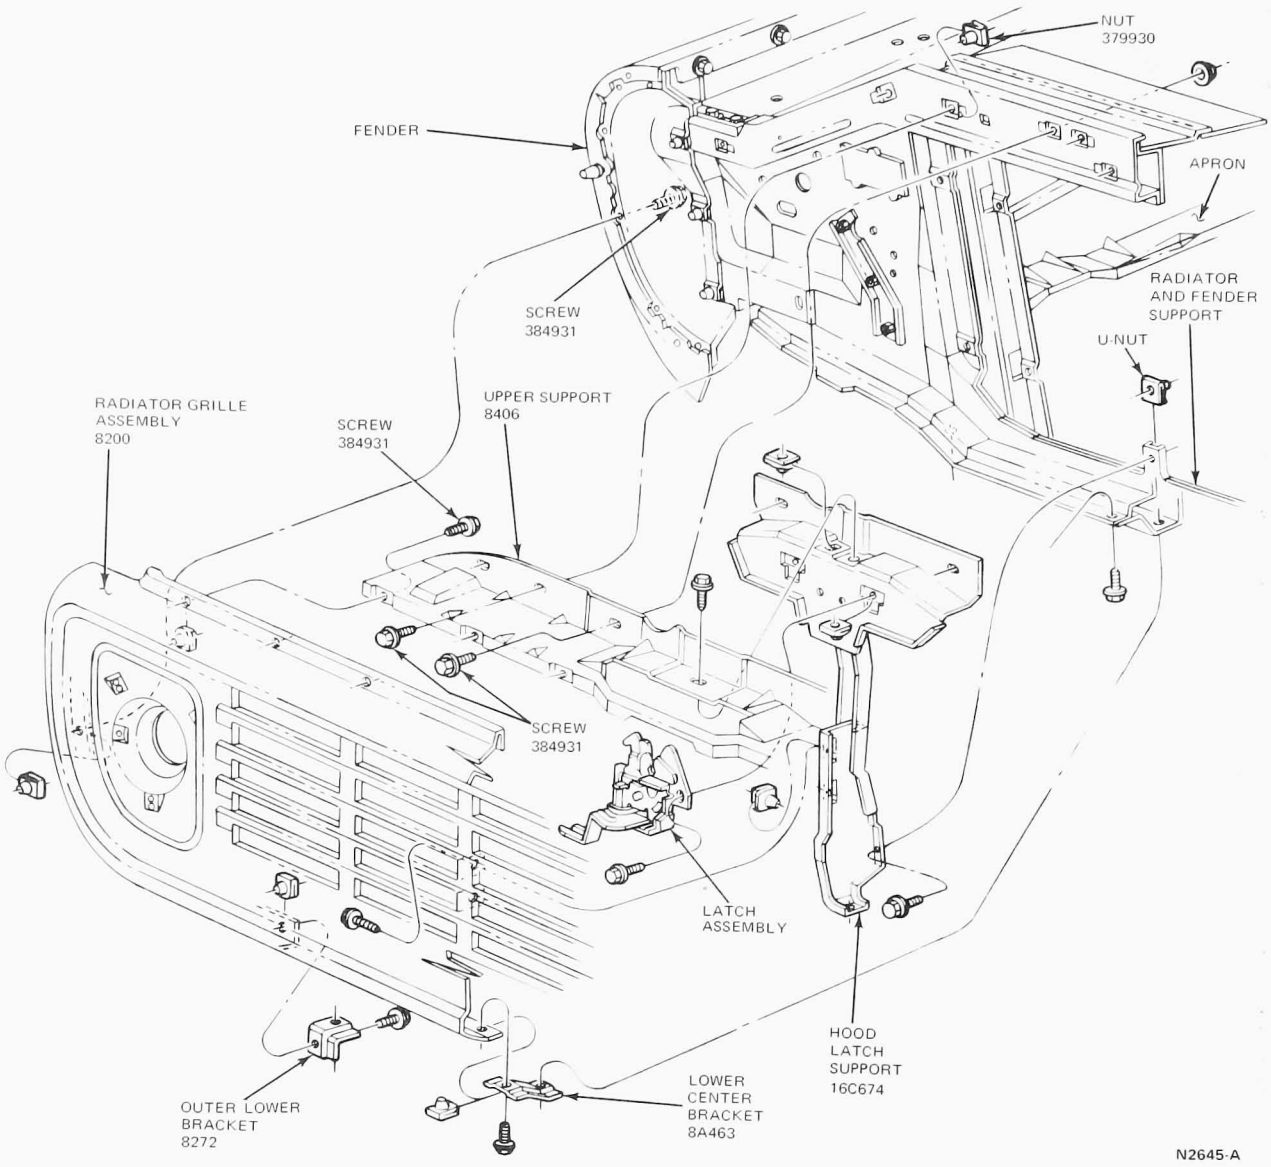

FIG. 1 Radiator Grille Installation—F-and B-500 through 750

COMPONENT INDEX	Page	COMPONENT INDEX	Page
MAJOR REPAIR OPERATIONS		REMOVAL AND INSTALLATION	
Fiberglass Repair	32-06	Body Sealer	32-03
Painting	32-06	Bumper – Front	32-01
Repair Procedure	32-06	Exterior Trim	32-03
Safety Precautions	32-06	Grille	32-01
		Running Board	32-01

REMOVAL AND INSTALLATION

RADIATOR GRILLE

Remove the six screws from the outside of the grille which retain the grille to the hood assembly (Fig. 1). Then, remove seven retaining screws and washers from the inside of the hood assembly and remove the grille.

FRONT BUMPER

Remove the bolts attaching the bumper to the bumper brackets and remove the bumper from the vehicle. To install the bumper, position the bumper to the bumper brackets and install the attaching bolts.

RUNNING BOARD

Removal

1. Remove the four screws retaining the upper running board to the lower running board and to the fender (Fig. 2).
2. Remove the two screws retaining the

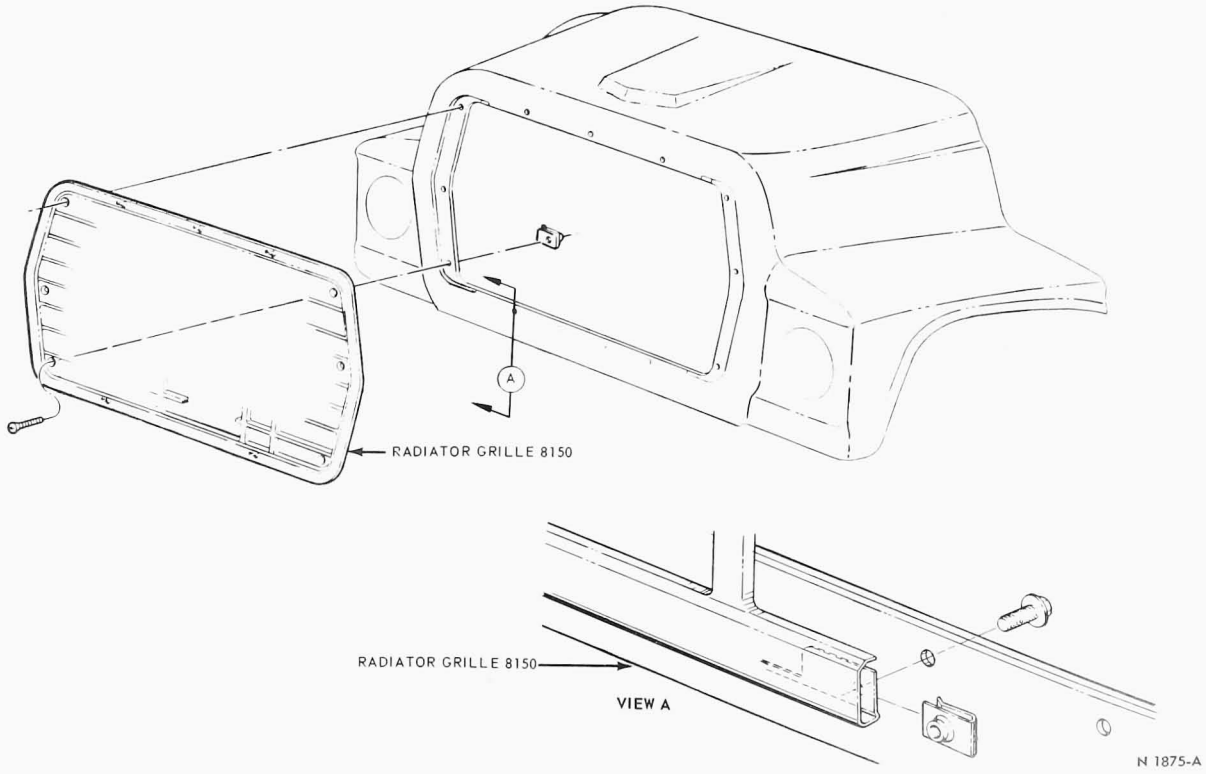

FIG. 1 Radiator Grille Installation—L, LN and LT-Series

upper running board to the running board front supports. Then, remove the upper running board.

3. Remove the screws retaining the lower running board to the running board rear support.
4. Remove the screw retaining the running board to the running board brace and remove the lower running board.
5. Remove the screws retaining the two front support brackets and the rear support bracket to the frame side rail and remove the brackets.

Installation

1. Position the two front support brackets and the rear bracket-to-frame side rail and install the retaining screws.
2. Install the lower running board by installing the retaining screws which secure it to the rear support bracket and brace (Fig. 2).
3. Position the upper running board to the front support bracket and install the retaining screws. Also install the screws retaining the running board to the fender and lower running board.

EXTERIOR TRIM

Before removing the exterior mouldings, determine by the type of retainer used if it is necessary to remove an interior trim panel (Fig. 3). If a weld stud is distorted or broken off, it should be replaced with a screw (379560-S101).

BODY SEALER

The sealer types and application procedures are given in General Information of Part 47-01. The test procedures for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

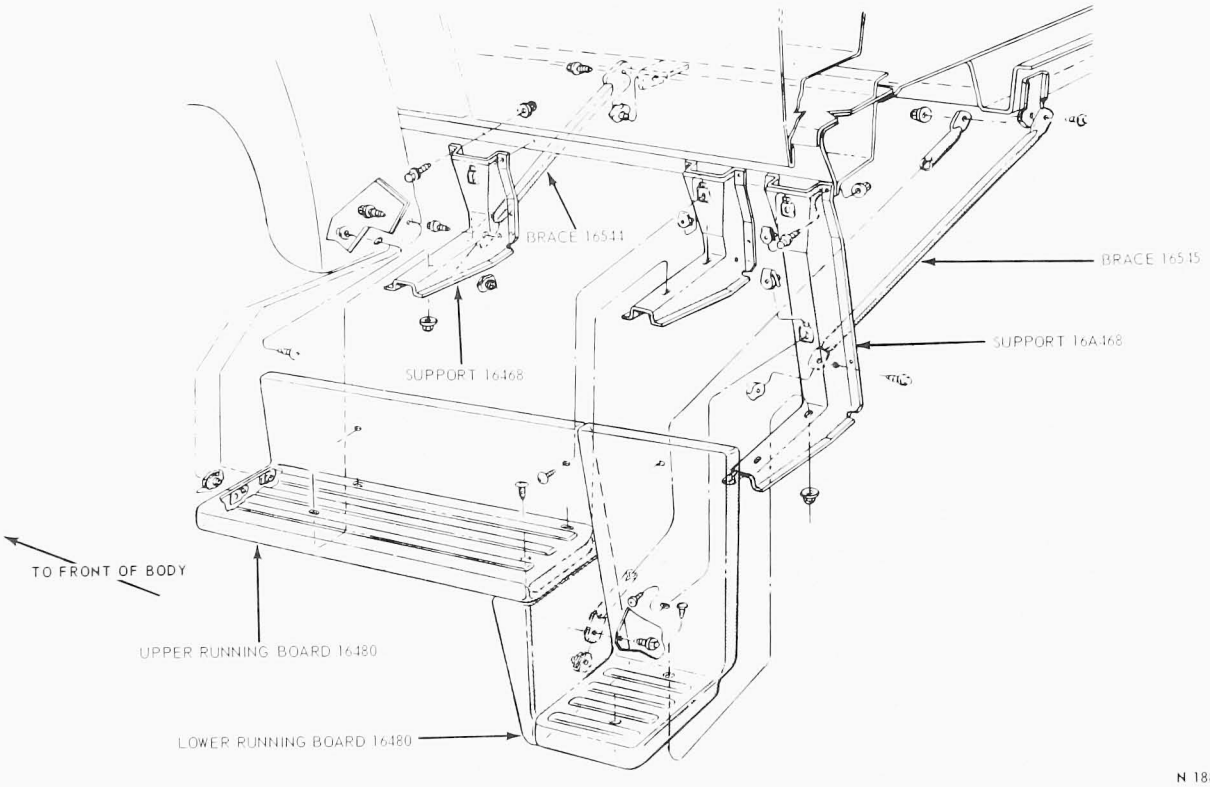

FIG. 2 Running Board Assembly—L-Series

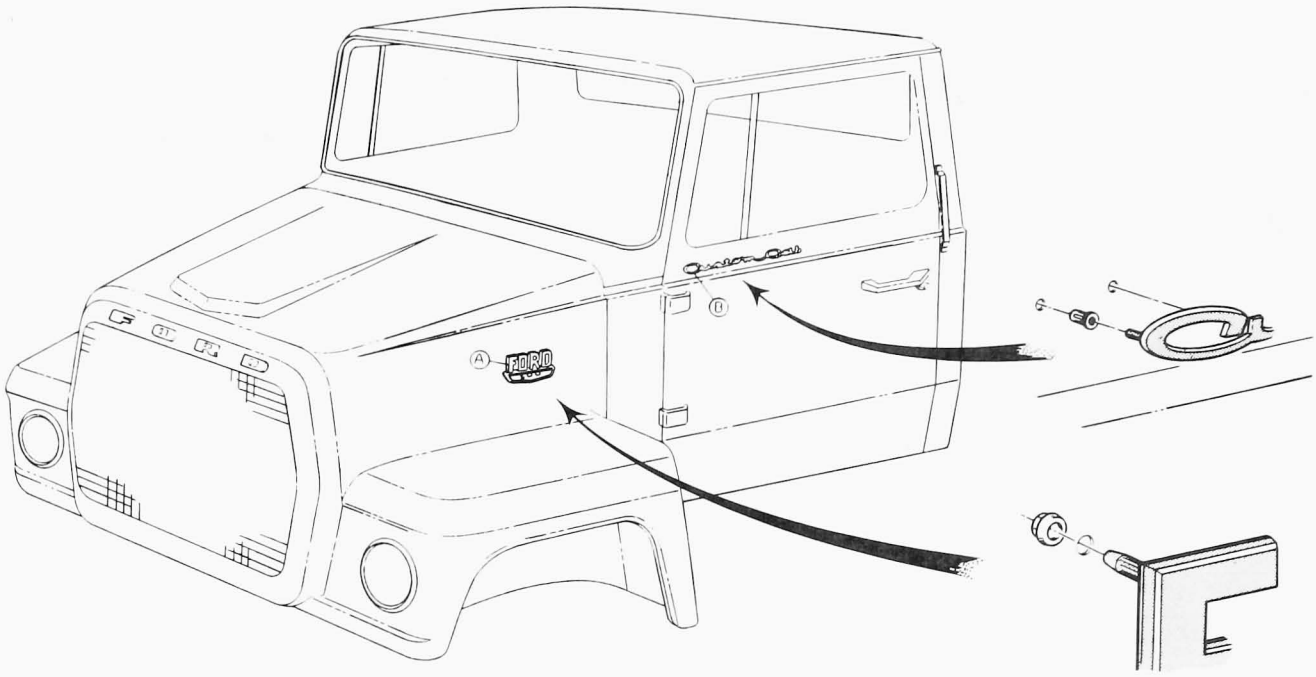

N 1880-A

FIG. 3 L-Series Exterior Trim

MAJOR REPAIR OPERATIONS

FIBERGLASS REPAIR

SAFETY PRECAUTIONS

Always use rubber gloves or the special hand cream supplied with epoxy resin repair kits. REMOVE ANY RESIN FROM THE HANDS AS SOON AS POSSIBLE AND PARTICULARLY BEFORE THE MIXTURE STARTS TO GEL. Any resin that adheres to the hands may be removed with lacquer thinner followed by a thorough washing with soap and water.

Use a respirator when grinding the fiberglass surface and use a vacuum attachment when operating a belt sander.

Always work in a well ventilated area in order to avoid possible toxic fumes that may result from using resin mixtures. Exercise care so as not to get any resin on clothing.

Keep all materials, utensils and the work area clean and dry as resin repairs involve chemical reactions. Any dirt, foreign material or moisture may upset the chemical reaction and result in an unsatisfactory repair.

REPAIR PROCEDURE

Grind or sand away all loose or broken material at the damaged area. Scuff sand the surface approximately one inch around the area to provide a good bonding surface. Be sure that the surface to be repaired is clean, dry, oil and paint free.

For cracks, form a shallow V along the crack with a file or grinder. Fill the area with a good quality polyester or epoxy body repair compound. Follow the manfacturer's directions with regard to mixing procedures. Allow the compound to harden and then sand smooth. If the surface is not level or smooth, use an additional filling and sand to a final smooth finish.

For larger broken areas use fiberglass cloth (five layers) impregnated with the resin, to cover the area. Overlap the damaged portion by one or two inches. When the material has hardened, file or grind and sand smooth. If low spots exist, fill them with resin mixture to which has been added short fibers cut from the fiberglass cloth. Add enough of the cloth to form a putty like resin mixture.

PAINTING

After the desired repaired surface has been obtained, prime and paint the surface in the normal manner.

Lock Assembly	34-3
Lock Cam	34-3
Lock Cam Hook	34-3
Safety Latch	34-3
Sleeper Cab	34-4
Tilt Assist Spring	34-3

DESCRIPTION AND OPERATION

TILT CAB MECHANISM

The C-Series cab is hinged at the front and will tilt forward approximately 45 degrees, permitting easy access to the engine and other chassis components. A double lock is provided at the rear of the cab. The handle release operates the main part of the lock, while the lock cam hook and the safety latch are each operated by a control rod.

Before tilting the cab, make sure that no loose articles are lying around in the cab. If the truck is equipped with a grille guard, this guard must be tilted before the cab is tilted. To tilt the cab, pull up on the operating arm, pull out on the lower control rod to release the safety latch (Fig. 1). Hold the cab and let it rise slowly.

The oil and water can be checked and/or added through the large access plate behind the right seat back (Fig. 2).

The cab hinges are mounted toward the forward end of the frame side rails. The hinges are composed of an upper half, a lower half, a large hinge pin, a hinge pin bushing, and a bushing cap. All linkages and controls are pivoted in the centerline of the hinge pins. Therefore, the hand brake mechanism, steering column, accelerator linkage, and shifter linkage all have pivot points or universal joints in the centerline of the cab pivot pins.

If the entire cab must be removed, as in case of an accident, remove the tilt assist springs, disconnect every pivot point which falls in the centerline of the hinge pins, remove the support arm and remove the two pivot pin bushing caps. Also disconnect the heater hoses, the cables, and the electrical wiring. Lift the cab off the chassis.

The tilt assist springs are of the coil type and are loaded at all times, even when the cab is tilted up. Therefore, to avoid injury, the spring removal procedure given in Removal and Installation should be strictly followed.

LOCK

The complete lock mechanism (Fig. 1) consists of a release handle, operating arm, lock cam, cam hook, hood striker, safety latch, and the hook release levers with control rods.

ADJUSTMENTS

LOCK ASSEMBLY

The cam hook and the secondary latch should both contact their individual strikers about 1/4 inch down from the top of the hook when the cab is lowered. Adjust the safety latch stop bolt to obtain proper contact of the safety latch to safety latch striker.

REMOVAL AND INSTALLATION

LOCK CAM

Removal

1. Tilt the cab and tie it down at a good working level.
2. Remove the clevis pin retaining the operating arm in the cam lever (Fig. 3).
3. Remove the forward cam nut, cotter pin, nut, and large washer, and pull the cam and lever assembly out of the cab.
4. Remove the rearward cam nut cotter pin, the nut, washer, cam lever, and large spacer.

Installation

1. On the rearward end of the cam (flattened end), install the large spacer and the cam lever. With the cam straight up, the lever should be pointing up and to the right at approximately a 45 degree angle.
2. Install the washer, nut, and cotter pin to hold the cam lever on the cam.
3. Position the cam in the cab, and install the large washer, nut, and cotter pin.
4. Connect the operating arm to the cam lever with the clevis pin.

LOCK ASSEMBLY

Removal

1. Remove the cab left-side bumper.
2. Remove each control rod cotter pin and washer, disconnect the safety latch and the cam hook control rods.
3. Remove the cotter pin and washer from the safety latch clevis pin out of the forward side of the radiator support.
4. Remove the two bolts and nuts retaining the lock assembly to the cab rear support, and remove the lock assembly (Fig. 3).
5. Remove the cam hook and the safety latch.

Installation

1. Install the cam hook and the safety latch with the release levers and return springs (see the two following procedures).

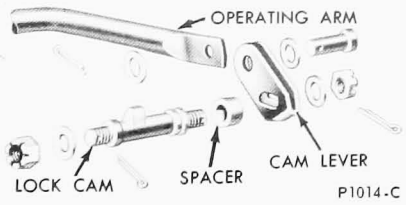

FIG. 3 C-Series Cab Lock Cam

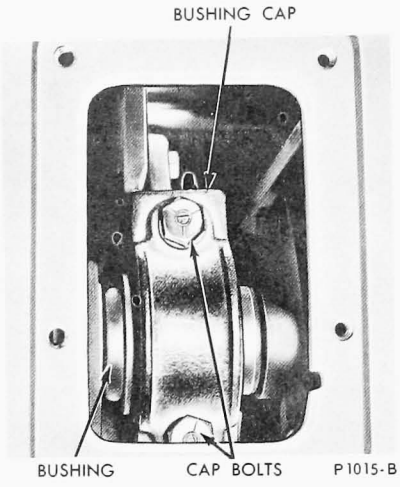

FIG. 4 Cab Hinge Pin Bushing Removal

2. Position the lock assembly in the radiator support, and install the retaining bolts and nuts.
3. Push the safety latch clevis pin through the forward side of the radiator support and install the washer and cotter pin.
4. Connect the safety latch and the cam hook control rods, and install the washer and cotter pin in each rod. Check the lock assembly operation. Adjust the lock assembly, if necessary.
5. Install the cab left-side bumper.

LOCK CAM HOOK

1. Remove the cam hook control rod cotter pin and washer.
2. Drop the cam hook down and disconnect the return spring from the small clevis pin.
3. Install the small clevis pin in the new hook with the hole end of the clevis pointing rearward.
4. Start the hook into position, and connect the hook return spring to the small clevis pin.
5. Start the large clevis pin through the forward side of the lock assembly, and then install two washers, the cam hook, one washer, the cam hook release lever, and one more washer on the clevis pin. Insert the clevis pin through the rearward side of the lock assembly, and install one washer and the clevis cotter pin.
6. Check the operation of the lock assembly, and adjust it if necessary.

SAFETY LATCH

1. Remove the lock assembly from the cab rear support.
2. Disconnect the latch return spring and the cam hook return spring.
3. Remove the safety latch clevis pin from the lock assembly, and remove the safety latch.
4. Install the clevis pin in the safety latch and the latch release lever, then insert the clevis pin through the lock assembly just far enough to hold it on the forward side.
5. Connect the cam hook return spring and the safety latch return spring.
6. Install the lock assembly in the radiator support.

HINGE PIN AND/OR BUSHING

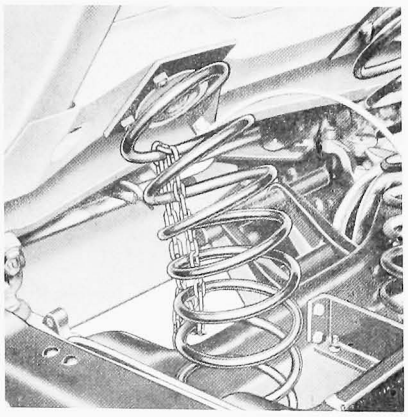
Removal

The hinge pin bushing cap, bushing, and hinge pin are accessible from above through an access hole in the floor pan.

1. Because of the extreme upward pressure of the tilt assist springs when the cab is down, the cab must be strapped down before the hinge pin cap is removed. Measure the distance between one of the hinge to cab bolts and one of the bumper lower bolts. Drill holes, shape a piece of strap iron, and install the strap iron between these two bolts.
2. If the left hinge pin is to be removed, remove the steering shaft universal joint. If the right hinge pin is to be removed, move the transmission cross-shaft lever out of the way.
3. Make sure the cab is firmly locked down at the rear. Roll back the floor mat, and remove the small access hole cover, on the toe board (Fig. 4).
4. Remove the cap retaining bolts and the cap.
5. From underneath, remove the hinge pin retaining nut, and knock the hinge pin out of the bushing with a brass drift.

Installation

1. Lubricate the inside of the hinge pin bushing with Lubriplate, position the bushing in the hinge, and drive the hinge pin through the hinge and bushing.
2. Install the hinge pin retaining nut loosely.
3. Position the bushing cap, and install the cap retaining nuts.
4. Tighten the hinge pin retaining nut, and install the cotter pin.
5. Remove the strap iron hold down.
6. Install the access hole cover, and position the floor mats.



P1016-B

FIG. 5 Assist Spring Chained Down

TILT ASSIST SPRING

The tilt assist springs are loaded even when the cab is tilted up. Follow this procedure carefully to save time and avoid a possible mishap.

Removal

1. Raise the cab. Have a helper hold the cab part way down, and place a chain between the first full coil at the top and the third coil from the bottom. Take all the slack out of the chain, and fasten the links together with a bolt and nut (Fig. 5).
2. Raise the cab and lock the support arm.
3. Inside the cab, roll back the floor mat and remove the upper spring saddle retaining nut (Fig. 6).
4. From underneath, remove the lower spring saddle retaining nut.
5. Remove the upper and lower spring saddles and saddle bolts. Remove the spring. It is not necessary to remove the support plate above the spring unless it is damaged. It acts as a floor pan reinforcement only.
6. If the spring which was removed is not to be used, it will be necessary to compress it in a press to remove the chain. Use Tool T54T-1175-E (rear wheel grease retainer replacer) in the top of the spring because it provides a good bearing recess for the press ram. Use a good sized board (on top of a steel block) below the spring. Drive a nail in the board to keep the spring from slipping sidewise. Place the spring over the nail and compress the spring carefully. Stand to the side of the press in case the spring slips out. When the chain is slack, remove it, and release the spring slowly.

Installation

1. If the spring to be installed is not strapped down, it must be compressed and chained on one side before it is possible to install it.

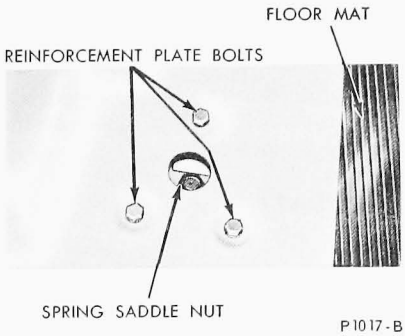


FIG. 6 Upper Spring Saddle Retaining Nut

In the press, place the spring over the nail in the board, place Tool T54T-1175-E in the top of the spring, and compress the spring until the measurement between the top of the first full coil and the bottom of the third full coil from the bottom is 9 inches (Fig. 7). Place the chain around these particular coils, take up all the slack, and fasten the links with a bolt and nut. The chain must be fastened in the above-mentioned coils or the spring will not bend properly when released. Also, the chain will interfere with the crossmember if fastened on any coil lower than the third from the bottom. Release the press slowly. Fig. 8 shows the spring tied down and ready for installation.

2. Position the tied down spring in the chassis, install the lower spring saddle and bolt, and run the nut on about three threads.
3. Install the upper spring saddle and bolt, and tighten the nut until all the slack is taken up.
4. Tighten the lower spring saddle bolt securely, and tighten the upper bolt.
5. Have a helper lower the cab about half-way, and remove the chain from the spring.

SLEEPER CAB

Removal

1. Disconnect the air hose retainer springs.
2. Remove the right and left upper ladder sections.
3. Remove the cab roof trim panels. Remove the sleeping compartment safety straps from the roof panel and remove the mattress and package tray trim panels. Using the upper ladder retainer bolt holes, attach suitable rope to the sleeping compartment to use as a lifting sling and attach a chain fall to the sling.
4. Remove the sleeping compartment-to-cab retaining bolts (Fig. 9).
5. With the aid of an assistant and the use of the chain fall, remove the sleeping compartment from the truck.

Installation

1. Apply sealer around the cab body opening (Fig. 9) and the seal surface of the sleeping compartment.
2. Position the upper back panel seal assembly on the truck cab.
3. With the aid of an assistant and a chain fall, position the sleeping compartment assembly on the truck. Be sure that the sleeping compartment-to-cab seal is properly positioned.
4. Remove the chain fall and sling.
5. Install the sleeping compartment-to-cab retaining bolts.
6. Install the cab roof trim panels, package tray trim panels, sleeping compartment mattress and the sleeping compartment safety straps.

BUMPER

Remove the bolts attaching the bumper to the bumper arms and remove the bumper from the vehicle. To install the bumper, position the bumper to the bumper arms and install the attaching bolts. Tighten the attaching bolts and nuts to 50-70 ft-lb (7/16 inch) and 75-105 ft-lb (1/2 inch) torque.

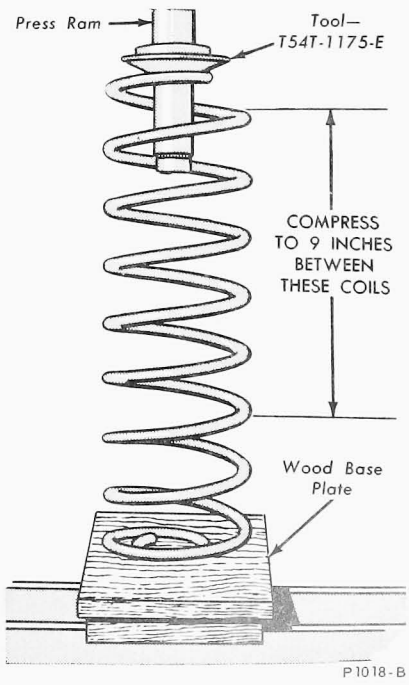

FIG. 7 Free Spring Mounted in Press

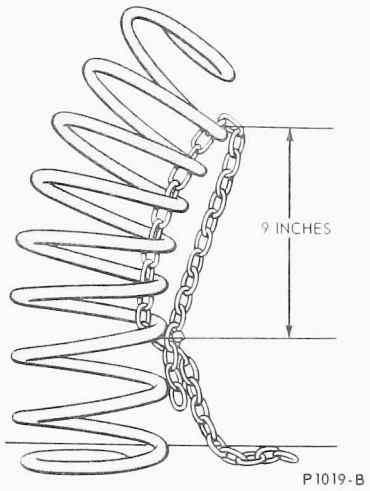

FIG. 8 Assist Spring Ready for Installation

EXTERIOR TRIM

The exterior trim installation and methods of trim attachment are shown in Fig. 10. When removing the exterior trim pieces, use care not to damage the vehicle exterior finish.

BODY SEALER

The sealer types are application procedures are given in General Information of Part 47-01. The test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

DESCRIPTION AND OPERATION

CAB TILT MECHANISM

DESCRIPTION

The W-Series cab is raised and lowered with a hydraulic cylinder which is actuated by a hand operated pump. The pump is located on the right side behind the cab. The pump is a three piece assembly consisting of the pump body, a reservoir, and a control valve.

Two safety features are incorporated in the tilt mechanism hydraulic system. One is an orifice that controls the fluid flow through the system, and controls the free-fall rate of the cab. The second safety feature is velocity fuses which are located in the hydraulic cylinder. These fuses are similar to a ball check valve and will isolate one section of the system and stop movement of the cab in the event of a hose failure.

The cab is locked down and released by two hydraulic latches.

OPERATION

There are two tilt positions for the cab; the first is 50 degrees and the second is 80 degrees. A stop pin in the control arm assembly will stop the cab from going farther than 50 degrees. With the 50 degrees stop pin removed, the cab can then be tilted the full 80 degrees. Whenever the cab is tilted 80 degrees, the radiator lower front grille must be removed to prevent damage to the grille.

After the cab has been partially raised by hydraulic action, it will pass an overcenter position. When this point is passed, no further pumping action is necessary since the weight of the cab will provide the force for further tilting. A valve in the pump will keep the rate of movement under control for safe operation.

Reversing the pump control lever (which is integral with the pump) and operating the hydraulic pump will lift the cab toward the drive position. Once again when the over-center position is reached, the weight of the cab will complete the lowering operation.

CAB TILTING INSTRUCTIONS TO LIFT CAB TO THE 50 DEGREE TILT POSITION

1. Remove all loose articles from the cab.
2. Apply the parking brake; place the transmission in neutral.
3. Move the control valve lever to the lift position (lever all the way outboard against the stop). Check the air and electrical cables and hoses to be sure that they will not catch on the engine or chassis and become damaged when the cab is tilted.
4. Pump the cab up until it passes the balance point and begins to descend. The cab will stop at 50 degrees.

80-DEGREE TILT POSITION

1. Remove the lower front grille panel.
2. Tilt the cab to 50 degrees as described above.
3. Remove the 50 degree stop pin. Adjust the control valve to the down position, (lever all the way inboard against the stop). Pump the cab down slightly to free the pin. Remove the pin. Do not force the pump handle as internal damage to the pump may result.
4. Re-adjust the control valve handle to the lift position (lever all the way outboard). The cab will tilt forward to 80 degrees.

TO LOWER THE CAB

1. **Be sure the transmission shift lever is in neutral.**
2. Adjust the control valve to the down position (lever all the way inboard). Check the air and electrical cables and hoses to be sure that they will not be damaged as the cab is lowered.
3. Pump the cab until it passes the balance point and begins to descend.
4. **Replace the stop pin if tilted to 80 degrees.**

SPECIAL INSTRUCTIONS

If the cab stops during free-fall descent:

1. Adjust the control valve to the opposite position.
2. Pump a few strokes to release the hydraulic safety lock.
3. Return the control valve to its original position for cab descent.

ADJUSTMENTS

CAB FREE-FALL RATE ADJUSTMENT

The free fall rate of the tilt system is controlled by two set screws located in the control valve portion of the hydraulic pump (Fig. 1). The set screws adjust the stop positions of the control lever. This restricts or opens the valve internal ports to increase or decrease fluid flow, and thus controls the free-fall rate. The rate is preset at the factory and normally will not need adjusting. If however, the free-fall rate is too great, an adjustment should be made.

CHECKING TILT MECHANISM RESERVOIR HYDRAULIC FLUID LEVEL

Remove the filler plug and observe the fluid level. It should fill the standpipe in the reservoir. If the fluid level is low, add fluid to fill the standpipe. **Use only hydraulic fluid which meets the MIL-H-5606-B specification.**

HYDRAULIC TILT MECHANISM BLEEDING INSTRUCTIONS

The following procedure should be followed to bleed air from the tilt mechanism hydraulic system.

1. The cab must be in the down (driving) position.
2. Loosen the hydraulic hose at the left cab latch hose fitting. Slowly operate the pump until all air is bled from the hydraulic hose and only fluid comes from the fitting.
3. Tighten the hose fitting at the left cab latch.
4. Repeat Steps 2 and 3 to bleed air from the system at the right cab latch.
5. Loosen the hose fitting at the frame (rear) end of the tilt cylinder.
6. Remove the filler plug from the reservoir and fill the reservoir to the top with hydraulic fluid meeting MIL-H-5606-B specification. Do not install the filler plug.
7. Move the control valve lever to the up position and slowly operate the pump. **If the pump is operated too fast, all the air will not be removed from the system.**
8. Slowly operate the pump until there are no air bubbles in the fluid coming out around the loose cylinder fitting. Then, tighten the fitting while operating the pump.
9. Check the fluid level and add fluid until the reservoir is full to the top of the standpipe.
10. Place the control valve on the pump in the down position and loosen the vent plug on top of the tilt cylinder near the cab attachment.
11. Operate the pump slowly until there are no air bubbles in the fluid coming out around the loose vent plug. Then, tighten the plug while operating the pump. **Do not over tighten the plug. It should be tightened only to 14-16 in-lb torque.**
12. Check the fluid level and add fluid until the reservoir is full to the top of the standpipe. Then, install the reservoir filler plug.

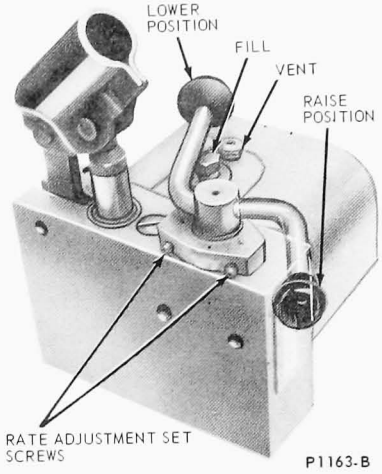

FIG. 1 Free-Fall Rate Adjustment

REMOVAL AND INSTALLATION

GRILLE

To remove the lower radiator grille it is necessary to remove the four retaining bolts. The upper radiator grille can be removed by removing the nine retaining screws from around the outer edge of the grille. Installation of the grille(s) can be accomplished by positioning the grille(s) to the vehicle and installing the retaining screws and/or bolts.

FRONT BUMPER

Removal

1. Disconnect the horn wire from the horn attached to the bumper.
2. Remove six of the eight bolts and nuts attaching the bumper to the bumper arms.
3. Remove the remaining two bolts and nuts and remove the bumper from the vehicle.
4. Remove the horn and license plate from the bumper if the bumper is to be replaced.

Installation

1. Install the horn and license plate on the front bumper.
2. Position the bumper to the vehicle and install one bolt and nut at each end of the bumper. Then, install the remaining six bolts and nuts and tighten all bolts and nuts to 75-105 ft-lb torque.
3. Connect the wire to the horn and check the operation of the horn.

CAB TILT CYLINDER

Removal

1. Remove the radiator lower grille from the front of the cab.
2. Release the cab latch and raise the cab. Then, remove the pin from the cab support arm and tilt the cab to the 80 degree position.
3. Place support stands under the top front edge of the cab. Use care to prevent damage to the cab or the paint.
4. Release the pressure from the tilt cylinder by moving the control valve

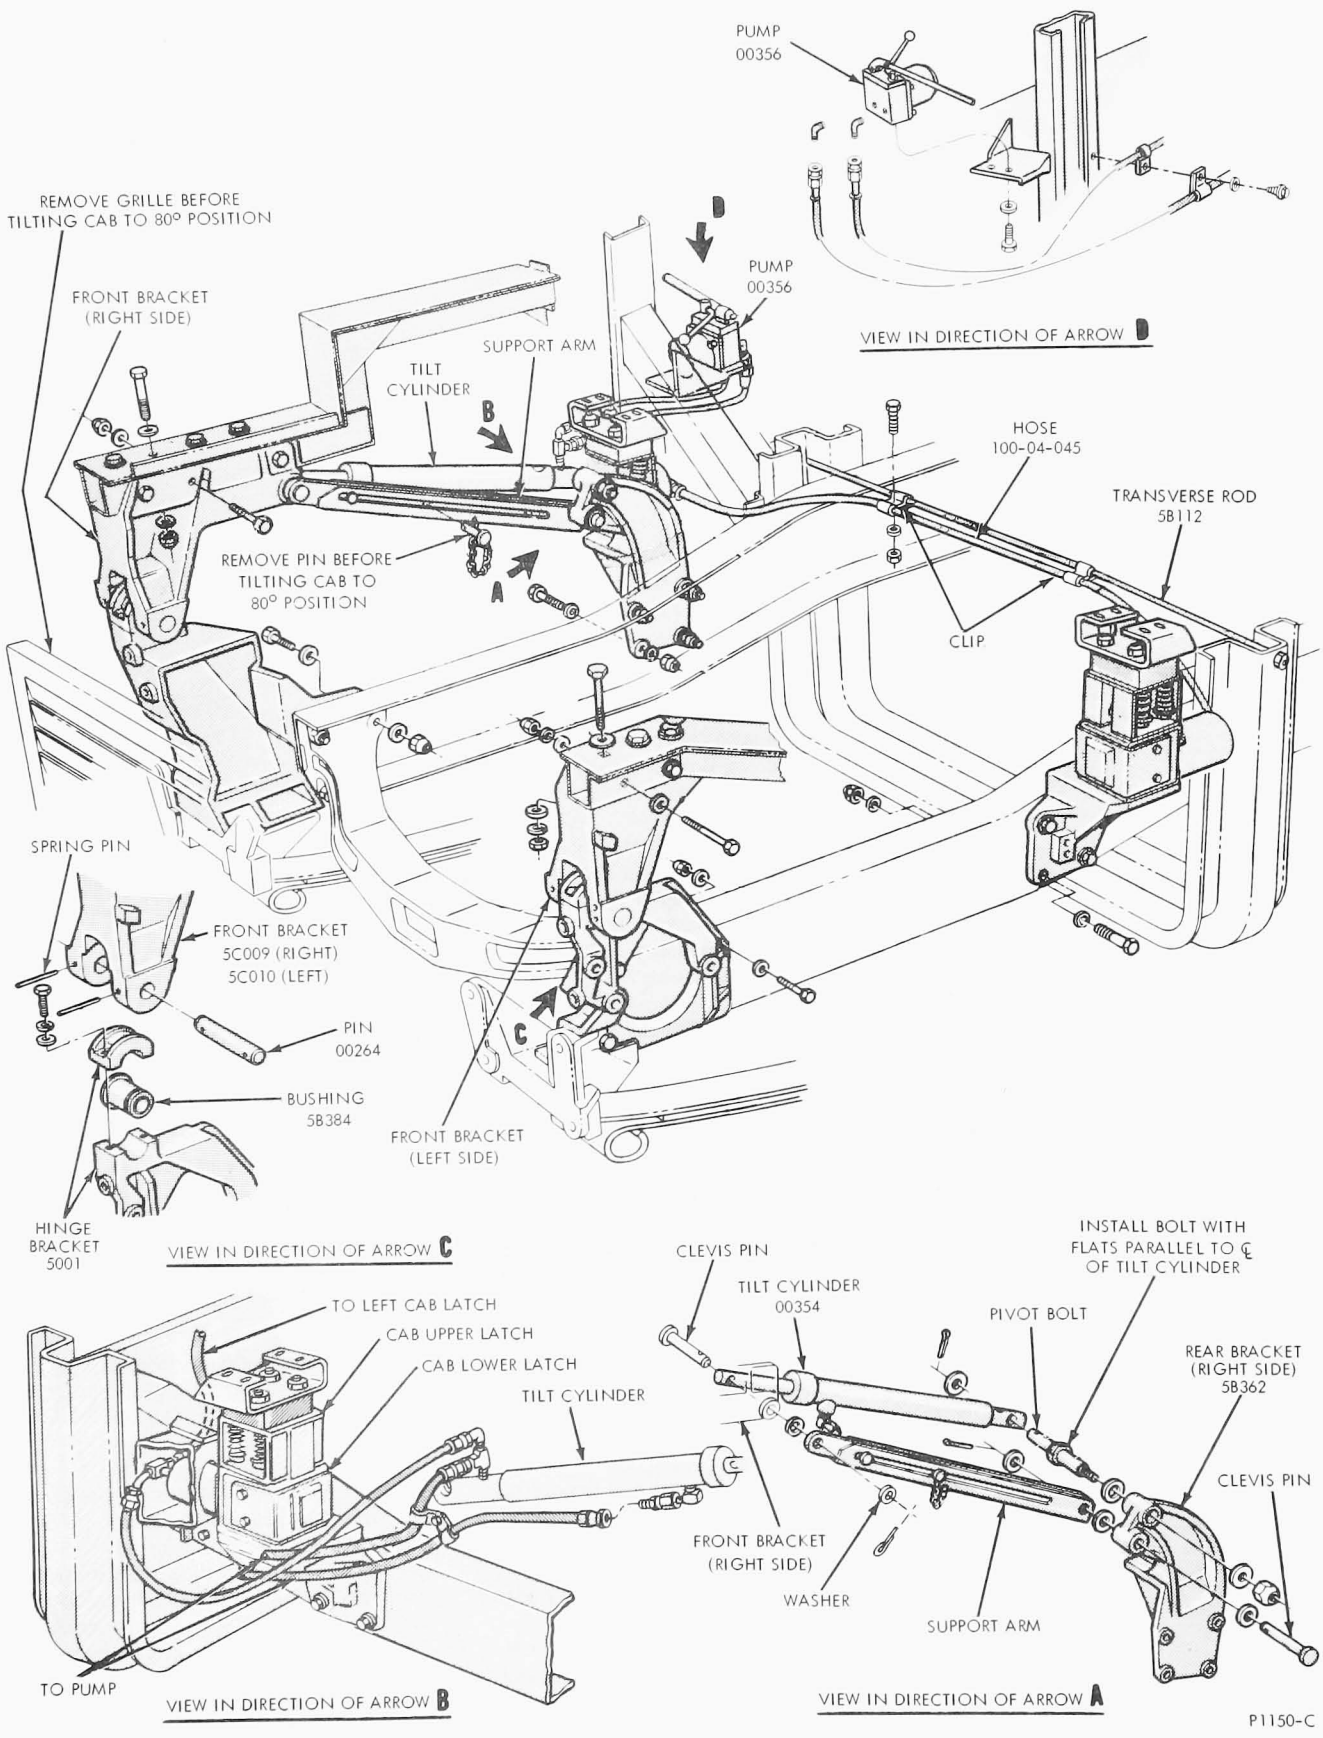

FIG. 2 Cab Tilt Mechanism—W-Series

lever to the down position.
5. Remove the cotter pin and washer from the tilt cylinder clevis pin and remove the clevis pin and washer from the front bracket (Fig. 2).
6. Remove the cotter pin and washer from the tilt cylinder pivot bolt (Fig. 2) and remove the cylinder from the pivot bolt.
7. Position a drain pan under the tilt cylinder. Disconnect the hoses from the fittings on the tilt cylinder and allow the fluid to drain from the hoses and cylinder.

Installation
1. Apply Loctite Sealer (C3AS-19554-A) to the threads of the cylinder fittings and connect the hoses to the fittings. Bleed all air from the hydraulic lines and cylinder as outlined in Adjustments.
2. Position the cylinder on the pivot bolt (Fig. 2), and install the washer and cotter pin.
3. Position the support arm, washer, and tilt cylinder to the front bracket (Fig. 2). Install the clevis pin. Position the washer on the clevis pin and install the cotter pin.
4. Raise the cab to the 50 degree tilt position and install the pin in the cab support arm. Then lower the cab and check the cylinder and hose connections for leaks.

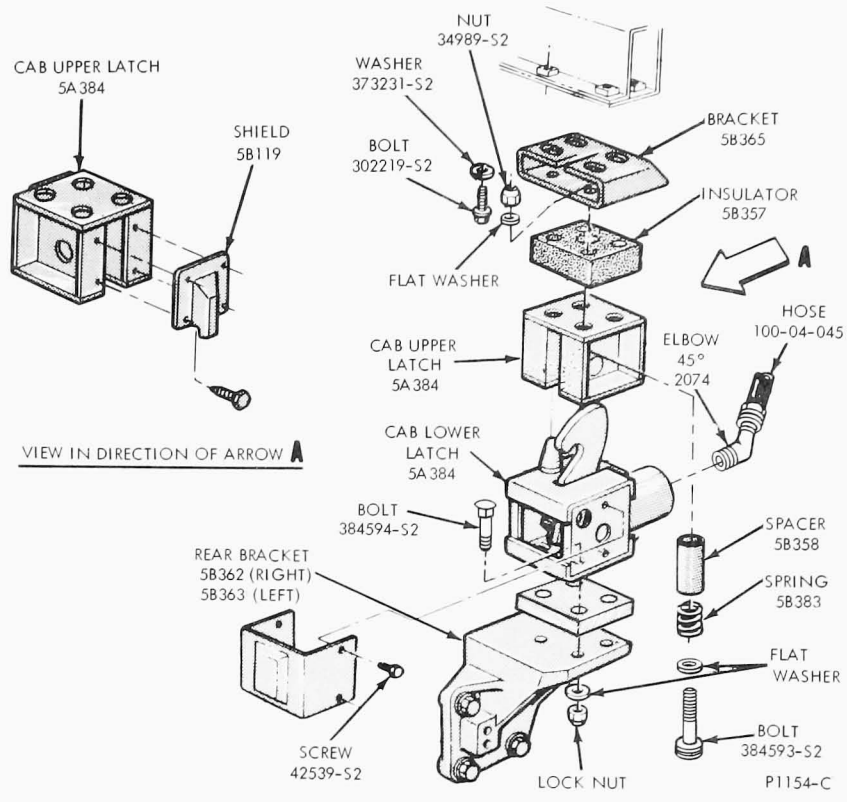

FIG. 3 Cab Latch Disassembled

CAB UPPER LATCH AND/OR INSULATOR

Removal
1. Tilt the cab.
2. Remove four bolts and washers attaching the cab upper latch, insulator, and bracket to the cab (Fig. 3) and remove as an assembly.
3. Remove four nuts, bolts, springs, washers, and bushings attaching the latch, insulator, and bracket together and separate the latch from the insulator and bracket.

Installation
1. Place the insulator and bracket on the latch and install the spacers, springs, washers, bolts, and nuts (Fig. 3) and tighten to 36-44 ft-lb torque.

Different insulators are used on the sleeper cab than on the standard cab. Be sure that the correct insulator is used if replacement is necessary.

2. Position the latch, insulators, and bracket assembly to the cab and install the four attaching bolts and washers.
3. Lower the cab and check the alignment of the upper latch with the lower latch. Align the two latches as required.

CAB LOWER LATCH

Removal
1. Tilt the cab to the 50 degree position.
2. Disconnect the hydraulic hose from the cab latch fitting.
3. Remove the dust shield from the latch.
4. Remove four nuts, bolts, and eight washers attaching the lower latch to the latch bracket (Fig. 3).
5. Remove the latch from the latch bracket.

Installation
1. Position the latch to the latch bracket and install the attaching bolts, washers, and nuts (Fig. 3).
2. Connect the hydraulic hose to the cab latch fitting. Leave the fitting 1/4 turn loose.
3. Operate the hand pump slowly to expel all air from the cab latch at the fitting.
4. Fill the pump reservoir with the specified hydraulic fluid (Adjustments Section).
5. Check the alignment of the upper latch and lower latch.
6. Install the dust shield on the latch.
7. Lubricate the latch mechanism as outlined in Adjustments.

EXTERIOR TRIM

The exterior trim installation and methods of trim attachment are shown in Fig. 4. When removing the exterior trim pieces, use care not to damage the vehicle exterior finish.

BODY SEALER LOCATIONS

The body sealer locations are shown in Figs. 5 thru 11. The sealer types and application procedures are given in General Information of Part 47-01. the test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

Body Sealer	51-3	Grille	51-1
Bumper	51-3	Long Roof	51-3
Frame Dimensions	51-3	Short Roof	51-3

REMOVAL AND INSTALLATION

GRILLE

Removal

1. Unlatch and raise the hood. Secure the hood in the open position with the catch on the windshield.
2. From the front under side of the left and right front fenders, remove the eight screws that secure the grille to the front fenders (Fig. 1).
3. Disconnect the left and right headlight bulb connectors and the parking light lead connectors.
4. Remove the six screws that secure the left and right headlight rims to the grille.
5. Remove the six screws that secure the left and right headlight adjusting rings to the grille brackets. Remove both headlight assemblies and the two ring springs.
6. Remove the three bolts that secure the hood hold-down latch on the grille to the radiator support assembly top rail.
7. Remove the grille assembly.
8. Remove the four bolts that secure the hood hold-down latch to the grille bracket. Remove the latch from the grille bracket.
9. Remove the four nuts and lock washers that secure the left and right parking lights to the grille. Remove both parking light assemblies.

Installation

1. Position the parking light assemblies in the grille openings and secure each light with two lock washers and nuts.

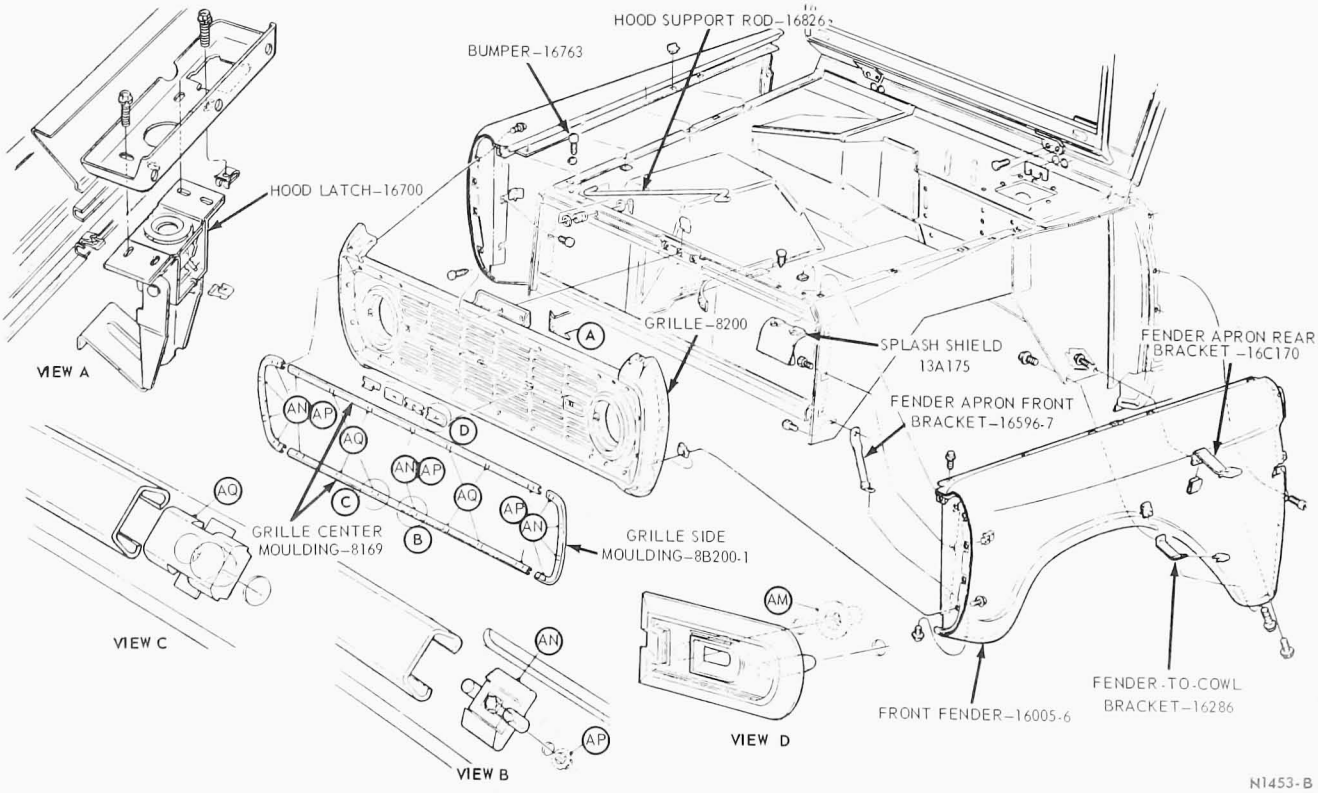

FIG. 1 Bronco grille, Fender and Hood Installation

2. Position the hood hold-down latch on the underside of the grille latch bracket and install four mounting screws.
3. Position the grille assembly and install the three bolts that secure the top center of the grille to the radiator support assembly top rail (Fig. 1).
4. Install the eight screws that secure the grille to the left and right front fenders.
5. Position the headlight assemblies and the ring springs on the headlight mounting brackets. Secure each assembly with three screws. **Before installing the headlight rims, the headlights must be adjusted.**
6. Perform the headlight adjustment procedures contained in Group 32.
7. Position the headlight rims and secure each rim with three screws.
8. Connect the headlight bulb connectors and parking light lead connectors.
9. Release the hood from the windshield catch and close the hood. The hood hold-down latch can be adjusted by loosening the latch mounting screws and shifting the latch until the hood lock catch centers in the latch opening. Tighten the latch mounting screws.

FRONT FENDER

The front fenders and related parts are shown in Fig. 1. Both front fenders and the grille can be removed as an assembly if necessary.

Removal

1. Unlatch and raise the hood. Secure the hood in the open position with the catch on the windshield.
2. From the front underside of the fender remove the four screws that secure the fender to the grille, and then remove the three screws that secure the fender to the apron and radiator support assembly.
3. Remove the screw from the fender flange that secures the front fender bracket to the fender.
4. Open the vehicle door and remove the three screws that secure the fender to the cowl hinge pillar.
5. Remove the screw from the lower fender flange that secures the rear fender bracket to the fender skirt.
6. While holding the fender in position, remove the five screws that secure the topside of the fender to the side apron. remove the fender.

Installation

1. Apply a bead of sealer on the fender mating surface of the side apron and on the front and rear mating surfaces of the fender.
2. Position the fender on the vehicle and install the five screws that secure the fender to the top of the side apron.
3. Secure the fender to the cowl hinge pillar with three screws.
4. Secure the apron and radiator support assembly with three screws and then secure the fender to the grille with four screws.
5. Secure the front and rear fender brackets to the fender with screws.
6. Release the hood from the windshield catch and close the hood.

BUMPER

Remove the bolts retaining the bumper to the bumper arms and remove the bumper from the vehicle. To install the bumper, position the bumper to the bumper arms and install the retaining bolts.

SHORT ROOF

Removal

1. Open the vehicle doors, and from inside the cab, remove the eight screws and lock washers that secure the short roof (Fig. 2) to the windshield frame retainers. Remove the retainers.
2. From inside the vehicle, remove the bolt, lock washer, and nut at the front of each side panel, and the six screws and lock washers that secure the short roof to the cargo compartment front panel and the cargo compartment front panel retainers (Fig. 2). Remove the retainers.
3. With the aid of a hoist or helpers, remove the short roof from the vehicle.

Installation

1. Before installing the short roof on the vehicle, inspect the weatherstrips attached to the windshield frame mating rail and the cargo compartment front panel mating rail (Fig. 2). Damaged weatherstrips should be replaced.
2. Apply adhesive to the roof and weatherstrip mating surface.
3. Position the short roof on the vehicle, making sure that the alignment dowels drop in the alignment dowel holes.
4. Check the alignment of the roof with the windshield frame and the cargo compartment front panel. When properly aligned, install the two bolts, lock washers, and nuts securing the short roof to the body side panels, the six screws and lock washers securing the roof to the cargo compartment front panel retainers, and the eight screws and lock washers securing the front of the roof to the windshield frame retainers. **Apply a daub of sealer (AB-19560-A) to each attaching screw or bolt hole before installation of the screws or bolts.**

LONG ROOF

Removal

1. Open the vehicle doors, and from inside, remove the eight screws and lock washers that secure the long roof (Fig. 3) to the windshield frame retainers. Remove tthe retainers.
2. From inside the cargo body, remove the bolt, lock washer, and nut at the front of each side panel, and the 12 screws and lock washers that secure the long roof to the cargo bed side rail and the side rail retainers (Fig. 3). Remove the retainers.
3. With the aid of a hoist or helpers, remove the long roof from the vehicle.

Installation

1. Before installing the long roof on the vehicle, inspect the weatherstrips attached to the mating surfaces of the roof side rails. Worn or damaged weatherstrips should be replaced. Inspect the mating cargo bed side rails. If they are bent or damaged, straighten and repair them as necessary.
2. Apply adhesive to the roof and weatherstrip mating surfaces.
3. Position the long roof on the vehicle making sure that the alignment dowels drop in the alignment dowel holes and the weatherstrips are in proper position.
4. Check the alignment of the roof with the door window frames, windshield frame, and tailgate. When properly aligned, install the two bolts, lock washers and nuts securing the front of the roof side panels to the body side panels, the 12 screws and lock washers securing the roof to the cargo bed side rail retainers, and the 8 screws and lock washers securing the front of the roof to the windshield frame retainers. **Apply a daub of sealer (AB-19560-A) to each attaching screw or bolt hole before installation of the screws or bolts.**

FRAME DIMENSIONS

The Bronco Frame Dimensions are shown in Fig. 4. The frame checking and repair procedures are given in Part 47-01.

BODY SEALER

The body sealer locations are shown

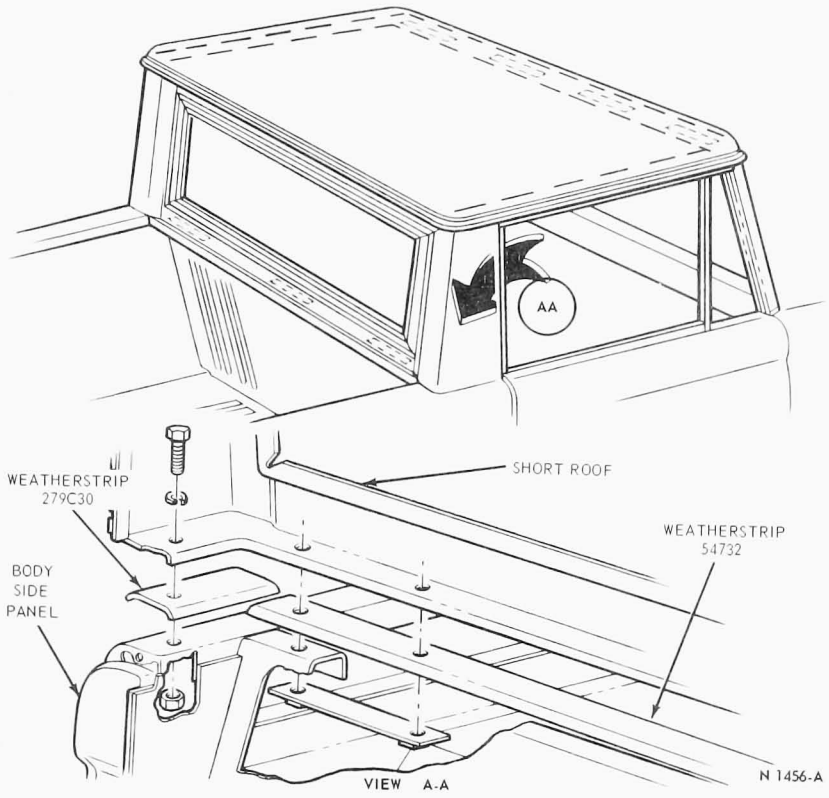

FIG. 2 Bronco Short Roof Installation

in Figs. 5 thru 10. The sealer types and application procedures are given in General Information of Part 47-01. The test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

EXTERIOR MOULDINGS

Before removing the exterior mouldings (Fig. 5), determine by the type of retainer used if it is necessary to remove an interior trim panel. If a weld stud is distorted or broken off, it should be replaced with a screw (379560-S101).

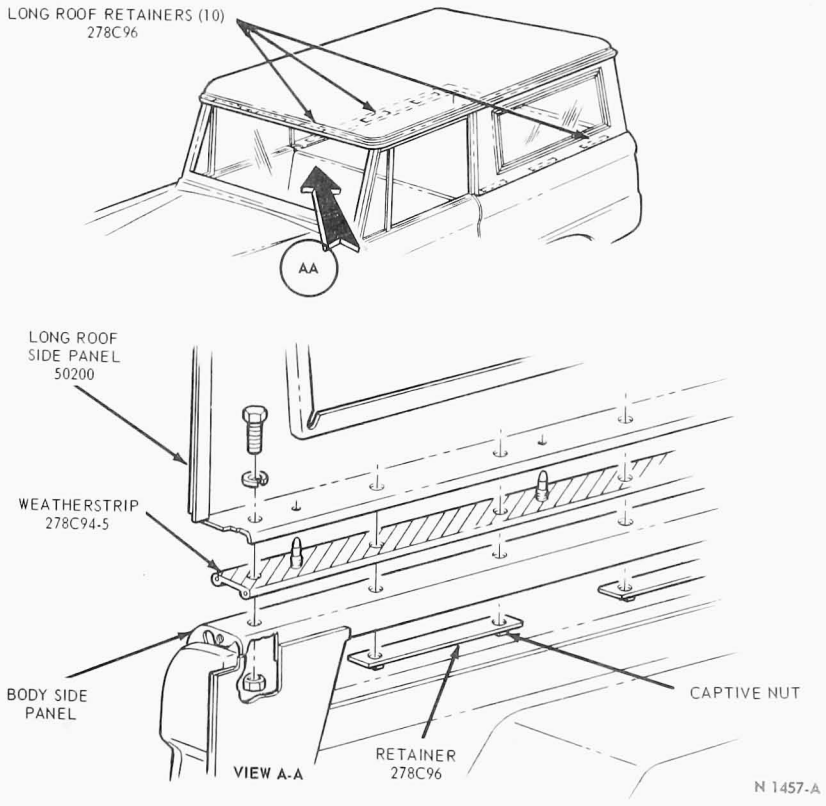

FIG. 3 Bronco Long Roof Installation

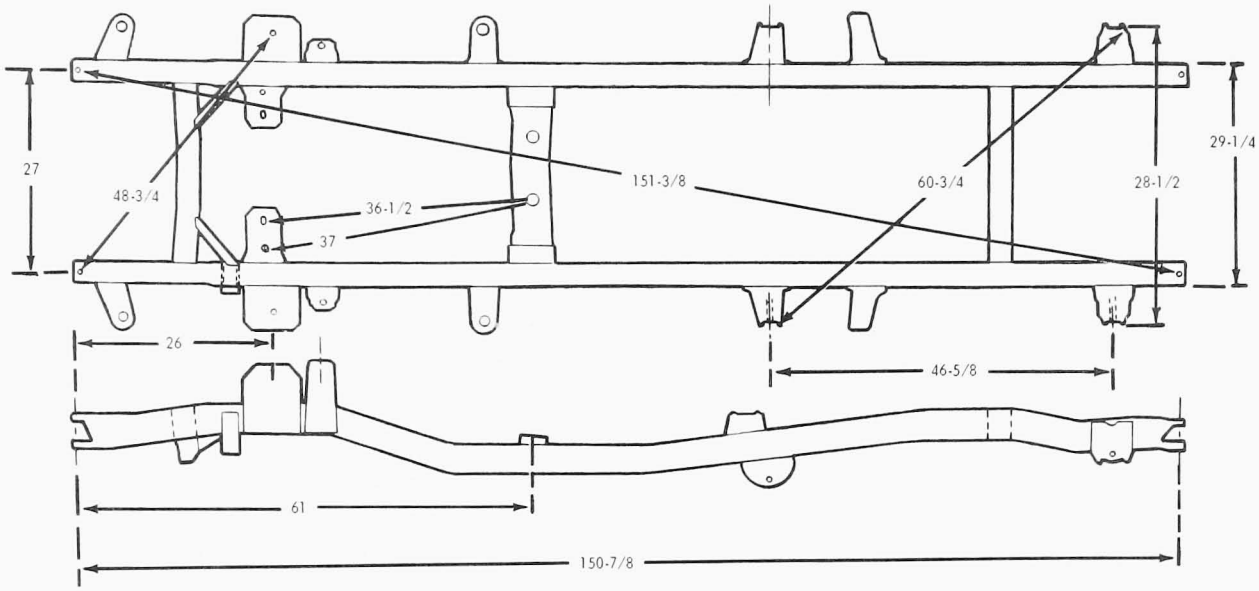

NOTE: ALL DIMENSIONS SHOWN SHOULD BE PROJECTED DOWNWARD AND MEASURED ON A LEVEL SURFACE. DIMENSIONAL VARIATIONS MUST BE IDENTICAL ON BOTH SIDES. VARIATIONS ON DIAGONAL UNDERBODY DIMENSIONS MUST ALSO BE IDENTICAL.

ADJUSTMENTS

CHECKING UNDERBODY

The dimensions of the underbody must be restored in the repair of major body damage, to provide correct front and rear wheel geometry (Fig. 1). All the dimensions are detailed to the centerline of existing holes in the underbody assembly. Once the frame and suspension members are aligned, the balance of the repair can be performed.

BODY ALIGNMENT

Servicing the Econoline unitized body should present no unusual difficulties or necessitate additional equipment other than that required for the conventional frame and body repair.

The application of heat and the use of heavy-duty jacks must be carefully controlled because of the difference in the gauge of the metal in the sub-frame of a unitized body and the stress points developed in a single welded unit construction. It is possible to pull damaged areas back into alignment with the use of light-weight jacks and hydraulic equipment without heating the metal. The Bronco body is a welded, assembled unit installed on a conventional type frame. The front fenders are removable, and when installed, require sealing at the door post pillars, front grille, and along the seams of the side aprons.

Rough out badly damaged areas before taking measurements for squaring up a body. If necessary, remove the glass from the damaged area to prevent damage. In severe cases, reinforcement brackets and other inner construction may have to be removed or cut to premit restoration of the outer shell and pillars without excessive strain on the parts. Straighten, install, and secure all such parts in place before attempting to align the body.

In cases of severe or sharp bends, it may be necessary to use heat. Any attempt to cold-straighten a severely bent bracket may cause ruptures of the welds and may also cause cracks in the bent part. Never heat the area more than a dull red.

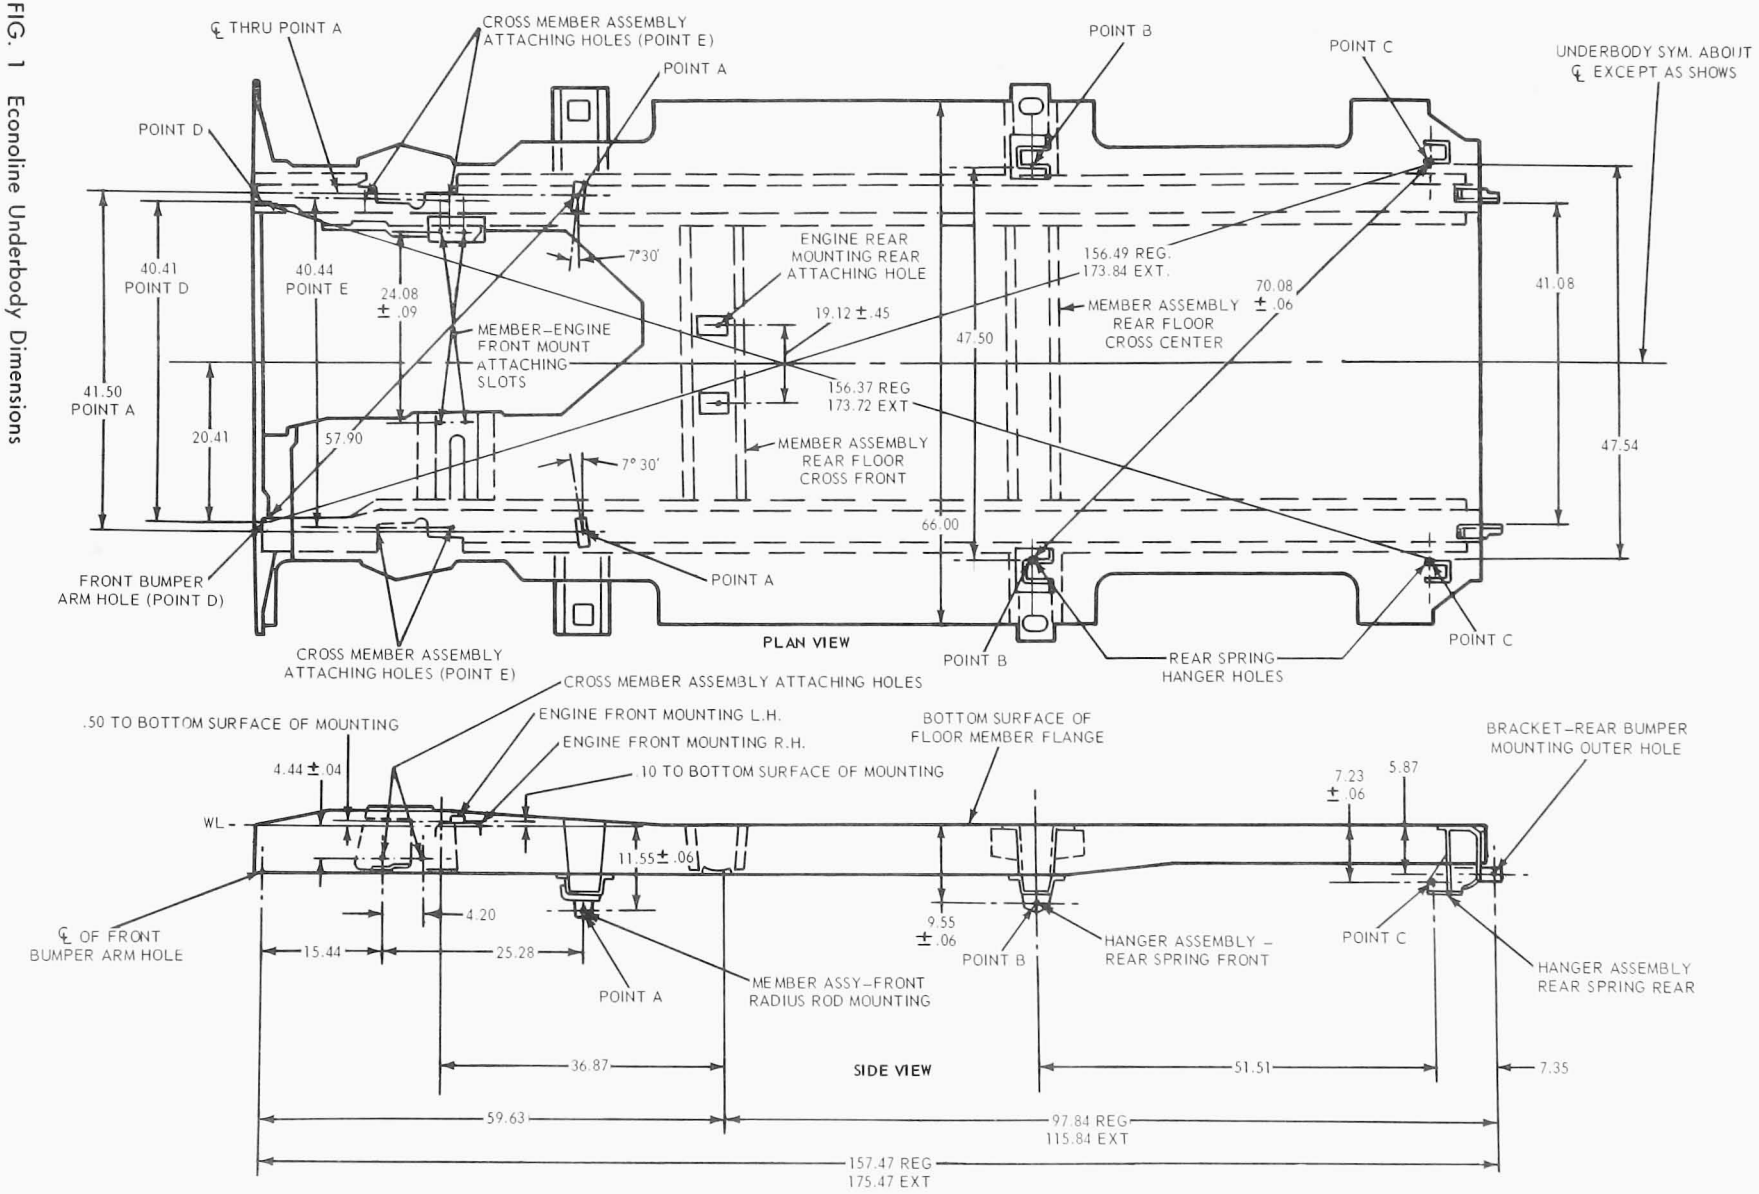

FIG. 1 Econoline Underbody Dimensions

REG – REGULAR BODY 105.5 W/B
EXT – EXTENDED BODY 123.5 W/B

ALL DIMENSIONS SHOWN ARE ±12 UNLESS OTHERWISE SHOWN AND SHOULD BE PROJECTED DOWNWARD AND MEASURED ON A LEVEL SURFACE. DIMENSIONAL VARIATIONS MUST BE IDENTICAL ON BOTH SIDES. VARIATIONS ON DIAGONAL UNDERBODY DIMENSIONS MUST ALSO BE IDENTICAL.

REMOVAL AND INSTALLATION

GRILLE

Removal

1. Remove the headlight doors, bulbs, and ring assemblies.
2. Remove five screws attaching the bottom edge of the grille to the front body member (Fig. 2).
3. Remove one screw attaching the hood latch support to the top edge of the grille.
4. Disconnect the parking light wires at the multiple connectors.
5. Remove one screw attaching each grille upper support (right and left) to the grille, and remove the grille.
6. Remove the hood support and two retainer clips from the grille (Fig. 2).
7. Remove the parking lights from the grille.
8. Remove the license plate and retainers from the grille.

Installation

1. Install the license plate and retainers, parking lights, and the hood support and retainer clips on the grille.
2. Position the grille to the vehicle and install the two upper support attaching screws (Fig. 2).
3. Install the five screws attaching the bottom of the grille to the body front member (Fig. 2).
4. Position the hood latch support to the grille and install the attaching screw.
5. Connect the parking light wires at the multiple connectors.
6. Install the headlight bulbs, doors, and ring assemblies. Then, adjust the headlights.

BUMPER

Remove the bolts retaining the bumper to the bumper arms and remove the bumper from the vehicle. To install the bumper, position the bumper to the bumper arms and install the retaining bolts.

AUXILIARY STEP

Removal

1. Disconnect the actuating lever rod from the door bracket.
2. Remove the cover from the actuating lever.
3. Remove the actuating lever rod from the actuating lever (Fig. 3).
4. Working under the vehicle, remove two screws attaching the step to the frame member (Fig. 3).
5. Remove one screw and nut attaching each end of the step to the body side flange at each end of the weatherstrip (Fig. 3).
6. Support the auxiliary step. Then, remove six screws attaching the step to the floor pan, and remove the step.

Installation

1. Lubricate the step hinge and pivot points with SAE 30 motor oil.
2. Position the auxiliary step to the vehicle, and install six screws attaching the stop to the floor pan.
3. Install two screws attaching the step to the frame member (Fig. 3).
4. Install two screws and nuts attaching the step to the body side flange.
5. Install the actuating lever rod on the actuating lever, and install the cover.
6. Connect the actuating lever rod to the door bracket (Fig. 3).

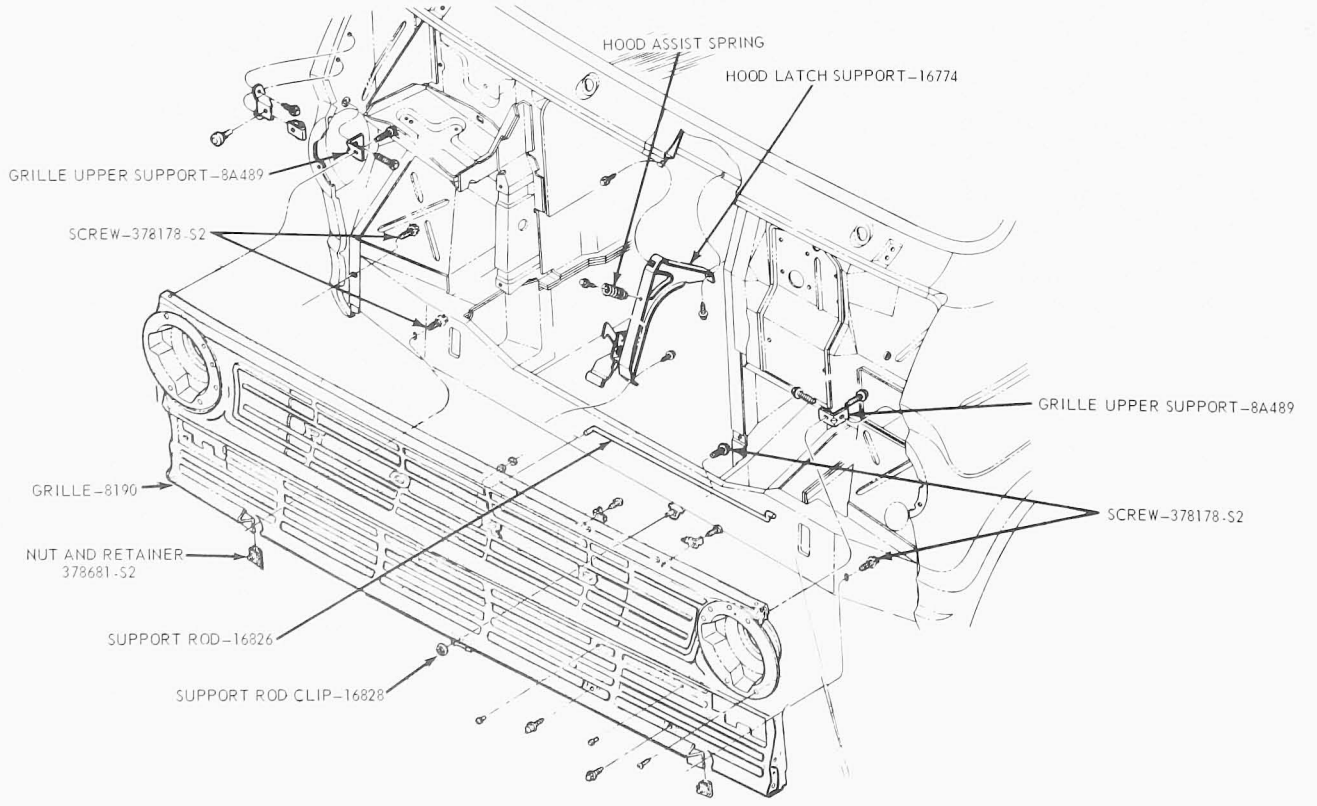

FIG. 2 Econoline Grille Installation

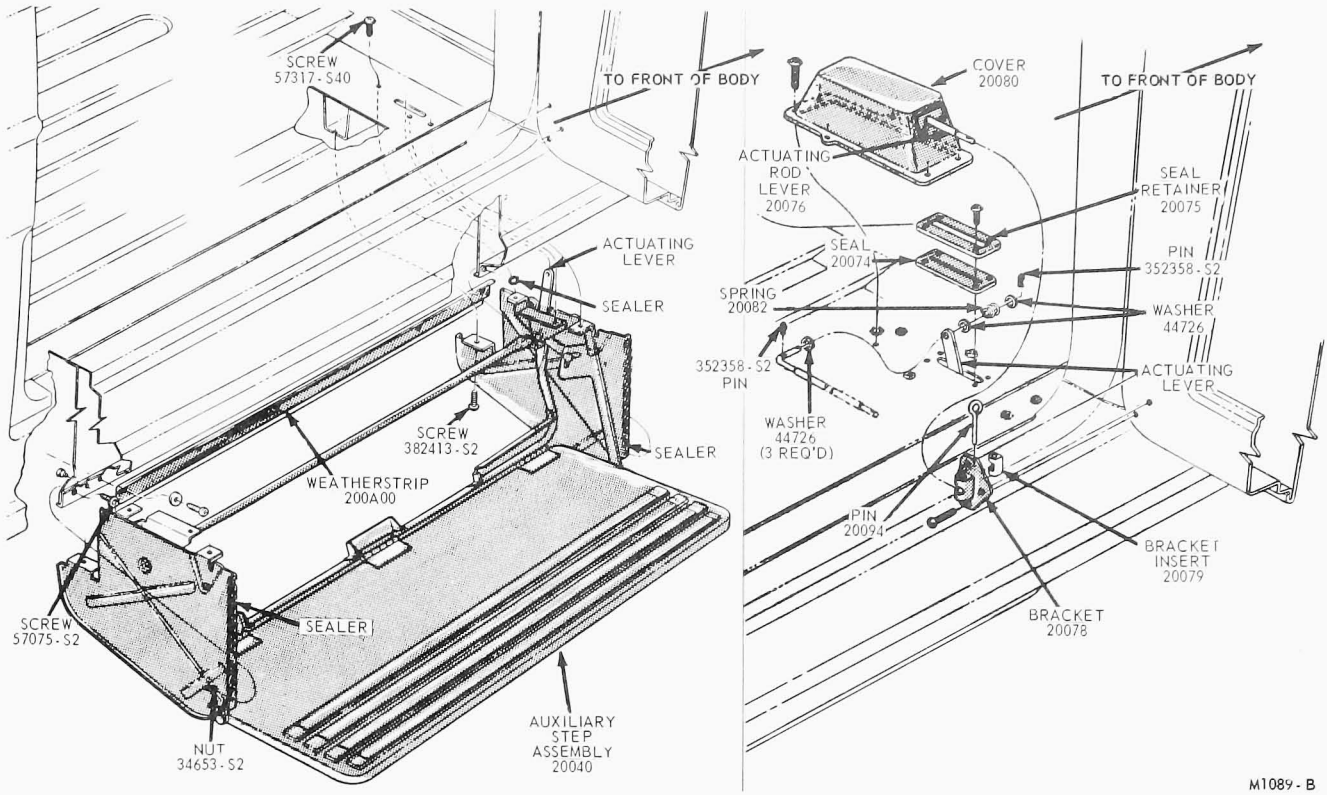

FIG. 3 Side Door Auxiliary Step Installation— Econoline

EXTERIOR MOULDINGS

Before removing the exterior mouldings, determine by the type of retainer used if it is necessary to remove an interior trim panel (Figs. 4 thru 6). If a weld stud is distorted or broken off, it should be replaced with screw (379560-S101).

BODY SEALER

The sealer types and application procedures are given in General Information of Part 47-01. The test procedure for locating dust and water leaks is given in Diagnosis and Testing of Part 47-01.

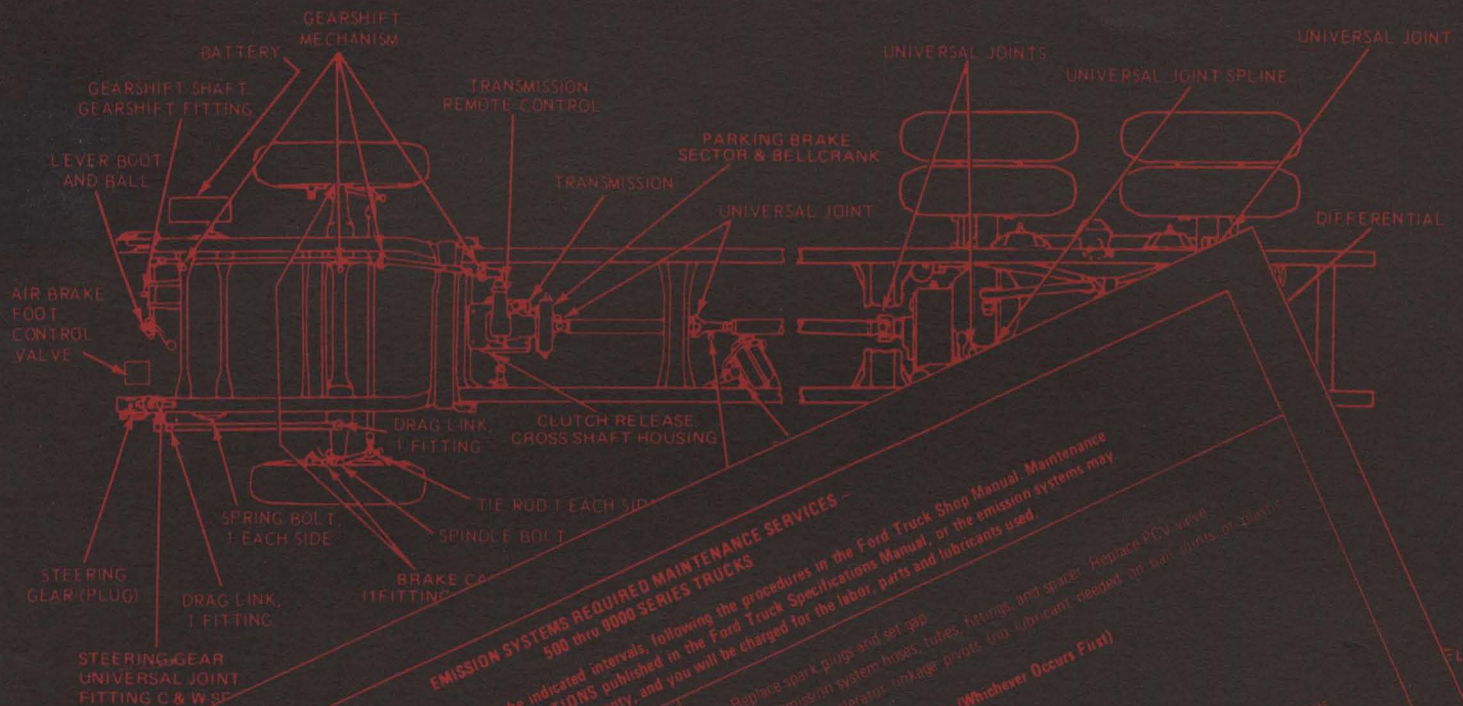
1973 TRUCK SHOP MANUAL



EMISSION SYSTEMS REQUIRED MAINTENANCE SERVICES
500 thru 9000 SERIES TRUCKS

The maintenance services must be performed at the indicated intervals, following the procedures in the Ford Truck Shop Manual, Maintenance Specifications Manual, or the emission systems may become inoperative. These services are not covered by the Warranty, and you will be charged for the labor, parts and lubricants used.

GASOLINE ENGINE MAINTENANCE SCHEDULE

Daily
Check dry type air cleaner restriction indicator, if so equipped, and clean element as required (1).

4,000 Miles or 4 Months (Whichever Occurs First)
Lubricate ... and clean and refill oil filter (2).
Clean and ... and check operation, if so equipped.

12,000 Miles or 12 Months (Whichever Occurs First)
Replace ... element if not equipped with restriction indicator (3).
... 401, 477, 534 C.I.D.
... leaks.
... equipped)
Torque ...
Inspect ... pressure of electric ... choke ...
Check ... and clean external choke ...
... speed and fuel mixture.
... ignition timing.
Replace if cracked or eroded.
... assembly and functioning of air cleaner intake ...
... wires for cuts, burns, ...
... correct ... loose terminal
Clean distributor cap, rotor and ...
Check for cutted ... system ...
temperature control system.
Check secondary ignition wires ...
abrasions or punctures.
Replace distributor breaker points and set gap.
and ground connection.
Clean ignition coil tower and check voltage output.

MEDIUM ... 5000

(1) ... (At first 6,000 miles only, thereafter ...
... miles only, thereafter every 5 ...
...chever Occurs First)
... (1). (At first 6,000 miles only, thereafter every 5 ...

... (1). (At first 6,000 miles only, thereafter every 5 ...
... miles only, thereafter every 5 ...

Replace spark plugs and set gap.
Clean emission system hoses, tubes, fittings, and spacer. Replace PCV valve.
Lubricate accelerator linkage pivots (no lubricant needed on ball studs or plastic bushings).

Each 24,000 Miles or 24 Months (Whichever Occurs First)
Replace fuel filter element (3).
Replace distributor cap and rotor.
Check and adjust distributor spark advance.
Lubricate distributor shaft bushing (oil cup).

At 24,000 Miles and 36,000 Miles
Test engine compression, all cylinders. Repair any cylinder below specifications.

DIESEL ENGINE MAINTENANCE SCHEDULE
Also see diesel engine Manufacturers Service Policy or Operators Manual.

Daily
Check fuel lines for leaks. Repairs as required.
Check air cleaner restriction indicator (1).

12,000 Miles or 12 Months (Whichever Occurs First)
Check air inlet piping and tighten clamps. More frequent intervals may be required under off highway or dusty conditions.

(1) Clean when restriction indicator shows red. Replace element after four cleanings or two years, or if damaged. Gasoline and Diesel E-engines.
(2) More frequent intervals required in dusty areas, high speed and temperature operation, extended idling, or frequent short trips.
(3) More frequent intervals may be required under off highway or dusty conditions.

...A MAINTENANCE
... shift main or auxiliary transmission (5).
... and 15 speed transmissions (5)
... mounting bracket bolts.
... gear lever.
Drain, ... and refill ... (5).
Torque ... bolts.
Check 2-speed axle electrical ... (4).
Lubricate Tachometer Drive Assembly (4).
Check Air Inlet Piping (Ford V-8 Diesel).
Clean Frame mounted booster air cleaner (C Series with hydraulic brakes).
Check Air Inlet Filter - MGM shortstop brake chamber (6).
Clean or replace air filter.
Clean or replace speedometer, parking brake and tachometer cables.
Lubricate speedometer, parking brake and clutch pedal pivot and linkage.
Check brake and clutch pedal pivot and hub.
Lubricate release bearing and hub.

...months (Whichever Comes First)
... 600 4 x 4) (6).
... (7).

FOREWORD

HOW TO USE THIS MANUAL . . .

It's A Vehicle Identification Guide. Part 50-01 contains the vehicle identification codes and illustrates how these codes are used on the Rating Plate. These codes are used to identify the vehicle and its components.

It's A Pre-Delivery Guide and Maintenance Schedule. Part 50-02 covers the Pre-Delivery Sequence Guide and the Scheduled Maintenance Services. The Pre-Delivery Sequence Guide when followed in the order presented in this manual, is designed to save time, avoid unnecessary steps, and prevent the overlooking of any recommended check point. Scheduled Maintenance Services list the intervals at which the services are to be performed. Also included is a chart of Non-Scheduled Maintenance items to be performed as required.

It's A Lubrication Guide. Part 50-03 is a guide to lubrication points on the 1973 Truck chassis. The specified lubricants are included in chart form, along with other pertinent information on oils and filters.

Part 50-04 provides information on vehicle jacking, towing and hoisting.

Parts 50-11 through 50-41 have detailed service information for items and components that are generally involved with periodic maintenance. **It is not a comprehensive repair manual.** For detailed information on all items, components and assemblies, refer to the appropriate volume and group of the 1973 Truck Shop Manual. An index is provided at the beginning of each part listing procedures covered and the page number.

The description and specifications in this manual were in effect at the time this manual was approved for printing. Ford Marketing Corporation reserves the right to discontinue models at any time, or change specifications or design, without notice and without incurring obligation.

FOR DIAGNOSIS AND SERVICE PROCEDURES ON EMISSION RELATED COMPONENTS, REFER TO VOLUME VI

PART 50-01 Identification Codes

GENERAL INFORMATION

VEHICLE CERTIFICATION LABEL

The Vehicle Certification Label (V.C. Label) is attached to the rear face of the driver's door. The upper half of the label contains the name of the manufacturer, the month and year of manufacture and the certification statement. The V.C. Label also contains the Vehicle Identification Number.

The remaining information codes on the V.C. Label are the same as the Truck Rating Plate Codes (Fig. 1). Vehicle codes shown on the Truck Rating Plate are explained in the following paragraphs.

RATING PLATE

Figure 1 illustrates a typical Truck Rating Plate. On light and medium cowl and windshield vehicles, the Rating Plate is mounted on the right side of the cowl top panel under the hood. On stripped Parcel Delivery vehicles, the rating plate is placed in an envelope and included in the boxed item parts. On Bronco models the plate is mounted on the inside panel of the glove compartment door. On all other vehicles, the Rating Plate is mounted on the rear face of the left front door.

VEHICLE IDENTIFICATION NUMBER

The identification number is the first

line of numbers and letters appearing on the Rating Plate (Fig. 1). The first letter and two numbers indicate the truck model and series (the letter prefix identifies the type of body or cab and the numbers are the first two numbers of a truck series). The letter following the truck series code designates the engine identification code. The letter following the engine identification code indicates the assembly plant at which the vehicle was built. The remaining numbers indicate the consecutive unit number. The charts in this part list the various vehicle identification number codes.

VEHICLE DATA

The Vehicle Data appears on the Rating Plate on the two lines following the identification number. The first three digits under W.B. designate the wheelbase in inches. The one or two letters under COLOR identify the exterior paint color (two letters designate a two-tone). The letter and three digits under MODEL designate the truck model within a series. The letter and numerals under BODY designate the interior trim and body type (the letter identifies the interior trim scheme and the numerals identify the body or cab type). The transmission installed in the vehicle is identified under TRANS by either a numeric or alphabetical code (if two symbols appear, the first identifies the auxiliary transmission, if so equipped, and the second symbol identifies the main transmission). A letter and a number or two numbers under AXLE identify the rear axle ratio (when required, a letter is also stamped behind the rear axle code to identify the front axle capacity). The maximum gross vehicle weight in pounds is stamped under MAX. G.V.W. A two-digit number is stamped under D.S.O. to identify the district which ordered the vehicle. If the vehicle is built to special order (Domestic Special Order, Foreign Special Order, Limited Production Option, or other special order), the complete order number will also appear under D.S.O. The charts in this part list the various vehicle data codes.

W.B. (WHEELBASE)

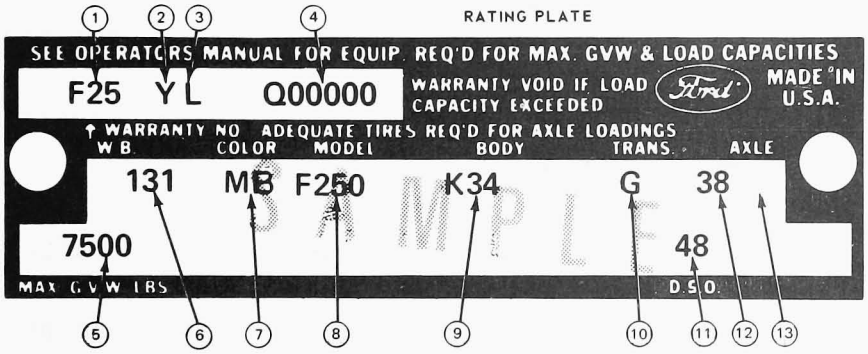
The wheelbase in inches is entered in this space.

MAX. G.V.W. LBS

The maximum gross vehicle weight in pounds is recorded in this space.

D.S.O.

If vehicle is built on a D.S.O., F.S.O., L.P.O. (special orders), the complete order number will be reflected under the D.S.O. space including the District Code Number.



VEHICLE CERTIFICATION LABEL

VEHICLE MAINTENANCE SERVICES	02-06	02-06	02-06	02-06	02-06	02-07	02-07	02-08	02-08

A page number indicates that the item is for the vehicle(s) listed at the head of the column.

MAINTENANCE

The scheduled and non-scheduled maintenance recommendations are included in this part for your reference. The emission systems required maintenance services and the vehicle maintenance services are separated on each maintenance schedule. Be sure to perform all maintenance services by referring to both parts of the maintenance services schedule.

Any modification of the emission control systems is subject to the penalties of federal law if made prior to the first sale and registration, and is subject to penalties under the laws of some states, if made thereafter. Further, federal law prohibits vehicle manufacturers or dealers from knowlingly removing or rendering an emission control system inoperative after sale and delivery to an ultimate purchaser.

PRE-DELIVERY SERVICES

BRONCO, ECONOLINE, F-100/350 and P-SERIES TRUCKS

PERFORM THE FOLLOWING INSPECTIONS AND ADJUSTMENTS AT THE DEALERSHIP	ROAD TEST AND INSPECT FOR PROPER OPERATION
All fluid levels – engine oil, brake master cylinder, windshield washer reservoirs, automatic transmission (hot), manual transmission and axle, power steering (hot), and cooling system (test coolant protection).	Steering column ignition lock.
	Starting of engine in park and neutral.
	Horn, windshield wiper and washer, lights, signals and instruments.
Recharge battery to 1.230 specific gravity.	Brakes (Including parking brake and warning light).
Throttle operation and idle return.	Operation of heater/defroster/ventilation system, radio, speed control and all other optional equipment.
Adjust curb idle speed, fast idle and engine timing.	Steering control
Align headlights as necessary.	Engine performance and driveability, including automatic choke function.
Install wheel covers, cigar lighter, radio antenna, mirrors, and roof rack.	Transmission/clutch performance.
Adjust tire pressures to specifications.	Squeaks and rattles.
Underside of vehicle for fluid leaks, steering linkage, suspension and removal of clamps or brackets used in-transit.	**CLEAN-UP**
Exterior parts of vehicle for proper appearance, operation and fit.	Wash vehicle.
Keys and operation of all locks.	Detail clean up of exterior and interior of vehicle.
Interior trim and appointments for proper appearance and fit.	Exterior metal and paint finish.
	Touch up paint and polish surface blemishes as required.
Operation of windows and vents.	Check glove compartment for warranty facts booklet, emission systems warranty and maintenance schedules booklet, owner card and owner publications.
Operation of seats and seatback latches.	Be sure starting instruction sleeve is on driver's side sun visor.
Operation of sunroof/convertible top.	Remove seat and carpet protective covers.

CY1550-A

500 THRU 900 SERIES TRUCKS

PERFORM THE FOLLOWING INSPECTIONS

AND ADJUSTMENTS AT THE DEALERSHIP

UNDER HOOD
ALL FLUID LEVELS: Check and fill as required – engine oil, automatic transmission, power steering reservoir, brake and clutch master cylinders, windshield washer, oil bath air cleaner reservoir, check coolant level and test.
Recharge battery to 1.230 specific gravity.
Check and adjust initial ignition timing.
Check and adjust idle speed and governor speed on governor equipped engine.
Check lines, fittings, connections and components for leaks, including audible leaks in air brake system.
ON INSIDE
Check window and vent operation and fit.
Check inside locks and door operation.
Install cigar lighter.
Check glove compartment for warranty facts booklet, emission systems warranty and maintenance schedules booklet, ownercard and owner publications.
ON OUTSIDE
Check latches, keys and locks operation.
Hood and doors for alignment and operation.
Torque wheel nuts and adjust tire pressure.
Install radio antenna (if so equipped).
Remove factory shipping protective material (except under hood at hood flange).
Torque rear axle nuts on saddle mounted units.
Check and adjust front wheel toe-in.

ON OUTSIDE (Cont.)
Inspect for exterior metal and paint damage.
Headlight aim.
Torque axle shaft flange nuts.
ON HOIST
Check lines for fittings, connections and components for leaks.
Adjust rear brakes on saddle mount deliveries.
Visually check front and rear suspension and steering.
Check rear axle and transmission lube level.
ROAD TEST
Check seat and track operation.
Check part-neutral switch (automatic transmission).
Check parking brake operation.
Check – horn, windshield washer and wiper operation.
Check all instruments, lights, turn signals and hazard warning flasher operation.
Check 2-3 speed axle operation.
Check radio operation.
Check brake, clutch and accelerator pedal operation.
Check transmission shift operation.
Check steering control.
Check for squeaks and rattles.
Check engine operation.
Check throttle and idle return.
Check heater, defroster, air conditioner and vent system.
Remove seat and floor mat protective covers.

CY1551-A

BRONCO, ECONOLINE and CLUB WAGONS, F-100 thru -350, M- and P-SERIES with GASOLINE ENGINES

EMISSION SYSTEMS REQUIRED MAINTENANCE SERVICES

These maintenance services must be performed at the indicated intervals, following the procedures in the 1973 Ford Truck Shop Manual. Maintenance service adjustments MUST CONFORM TO SPECIFICATIONS published in the 1973 Ford Truck Specifications Manual, or the emissions systems may become inoperative. These services are not covered by the Warranty, and you will be charged for the labor, parts and lubricants used.

Severe Service Operation

When operating your car under any of the following conditions, change engine oil every 2 months or 2,000 miles and oil filter every 4 months or 4,000 miles, check spark plug wires resistance, and clean and regap spark plugs every 4 months or 4,000 miles whichever comes first:

- Extended periods of idling or low-speed operation such as off-road or door-to-door delivery service.
- Towing trailers over 2,000 pounds gross loaded weight for long distances.
- Outside temperature remains below + 10° F. for 60 days or more and most trips are less than 10 miles.
- In severe dust conditions.

Adjust, repair or replace as required.

③ Clean exhaust passages in EGR valve, carburetor spacer, and intake manifold (V-8 engines).

④ If coolant is dirty or rusty in appearance, the system should be cleaned and flushed. The radiator cap should be cleaned and the system refilled with the prescribed solution of Ford Cooling System Fluid and water.

⑤ Drain and flush cooling system, and replace cooling system fluid – each 24 months regardless of mileage.

⑥ More often if operated in severe dust conditions.

⑦ Using 91 octane regular fuel (gasoline grade 2 under the preferred SAE rating system). When using leaded fuel (gasoline grade 3 or higher under the preferred SAE rating system) and extended periods of low speed operation, change spark plugs each 8,000 miles.

⑧ Change engine oil filter every 4,000 miles on trucks with dual rear wheels.

⑨ Bronco, Econoline E-100-200, Club Wagon, F-100 and all California vehicles built after January 1, 1973.

⑩ Bronco, Econoline E-100-200, Club Wagon, and F-100.

⑪ Bronco, Econoline E-100-200. Club Wagon, and F-100 and F-250-350 with 360-390 engines in California.

Emission System Abbreviations:

TRS – Transmission Regulated Spark Control System
PCV – Positive Crankcase Ventilation System
EGR – Exhaust Gas Recirculation System

① Clean when restriction indicator shows red. Replace element after four cleanings or two years, or if damaged. Gasoline and diesel engines.

② More frequent intervals required in dusty areas, high speed and temperature operation, extended idling, or frequent short trips.

③ More frequent intervals may be required under off-highway or dusty conditions.

④ Adjust, repair or replace as required.

⑤ If so equipped.

⑥ No lubricant needed on ball joints or plastic bushings.

⑦ Also see diesel engine Manufacturers Service Policy or Operators Manual.

⑧ Check and correct for loose terminal and ground connection.

① Each 1,000 miles in off-highway operation.

② To check the axle lubricant the plug should be backed out slowly. If seepage occurs around the threads, the specified amount of lubricant is present and the plugs should be turned back immediately to avoid any drainage.

③ Drain and refill daily when operating in water.

④ Perform daily when operating in water. Include repacking the free-running hub bearing is so equipped.

⑤ Rotate only wheels with tires of same size and ply rating every 8,000 miles.

⑥ More frequent intervals may be required under adverse operating conditions.

⑦ Replace front and rear wheel seals whenever a hub assembly is removed.

⑧ Drain all transmissions daily if level indicates entrance of water.

⑨ Change rear axle lube in Dana rear axles every 4,000 miles if towing a class II or III trailer.

(1) Refill Rockwell Axles with SAE 140.

(2) Replace each 500 miles in off-highway operation.

(3) Each 500 miles off-highway.

(4) More frequent intervals may be required under adverse conditions.

(5) Change each 8,000 miles in off-highway operation.

(6) Each 12,000 miles in off-highway operation.

(7) Refer to respective manufacturers engine operators manual.

(8) Replace front and rear wheel seals whenever a hub assembly is removed.

(9) Clean breather and magnetic plug, if equipped, when checking fluid level.

(10) Torque check and tighten.

(11) Each 24,000 miles in off-highway operation.

BRONCO, ECONOLINE, F-100-350, M- and P-SERIES

NON-SCHEDULED MAINTENANCE

The following maintenance operations are not required at definite mileage or time intervals, but should be performed when needed. These services are not covered by the warranty. You will be charged for the labor, parts and lubricants used.

MAINTENANCE OPERATION	WHEN PERFORMED
• Clean body/door drain holes.	• At least twice annually.
• Check clutch master cylinder fluid level (M- and P-Series).	• Sluggish clutch action or gear clashing when shifting.
• Check battery and recharge if the specific gravity falls below 1.230.	• Starter turns engine more slowly than usual. Headlights brighten when engine speeded up from idle.
• Check connections for tightness and corrosion.	• Light beam appears too high or too low while running with normal vehicle load.
• Check headlamp alignment.	• Pedal travel is more than half the distance between the released position and the floor.
• Adjust Service Brakes (M-500, P-500).	• Parking brake does not hold the truck stationary on a reasonable grade.
• Adjust parking brake.	• Starter will not engage with transmission selector in park and/or neutral, or back-up light does not operate.
• Adjust Automatic Transmission neutral switch.	• Doors bind during opening or closing, or noisy operation.
• Lubricate door hinges, tracks and checks.	• Poor handling characteristics and/or abnormal tire wear are experienced.
• Check front wheel toe and tire and wheel balance.	• Loose steering, slack in steering system, shimmy.
• Adjust steering gear preload, steering linkage or front wheel bearings. Check suspension and frame for loose attachments.	• Within 500 miles of either new vehicle delivery or any removal of wheel.
• Check wheel nut torque.	• Abnormal accelerator pressure is required to downshift transmission.
• Lubricate automatic transmission kickdown linkage. (F-100-350 (4 x 2), P- and M-Series – 6 cylinder only.)	• Linkage action is sluggish.
• Lubricate clutch linkage and standard transmission linkage. To avoid attracting dust and grit to the lube points, do not over-lubricate.	• Accelerator action is sluggish.
• Lubricate accelerator linkage lightly with the specified lubricant.	• Wiper blades do not clean windshield after windshield and blades have been cleaned.
• Replace windshield wiper blades.	• While the vehicle is hoisted for lubrication.
• Check the spring leaves for being evenly stacked and the spring clips or "U-bolts" for being tight.	• When front wheel alignment is checked.
• Check steering stop adjustment (M- and P-Series).	• When hard shifting in encountered.
• Check and adjust transmission controls and shift operation.	• When hard steering is encountered.
• Check steering gear lubricant level (4 x 4).	• Poor handling characteristics and/or abnormal tire wear are experienced.
• Inspect tires and check tire pressures.	• Driving conditions or inspection indicates looseness.
• Torque check frame mounted fuel tank strap bolts.	• At frequent intervals when operating off-highway or if front wheel shimmy is experienced.
• Remove excessive mud build-up from wheels, undercarriage, and steering linkage (4 x 4).	• If washers do not spray fluid when operated.
• Check windshield washer fluid level – add fluid if required.	• If tailgate binds during opening/closing or noisy operation.
• Lubricate tailgate hinges.	• As required.
• Check alternator output.	• As required.
• Check voltage regulator.	• As required.
• Check operation of lights, turn signals, horn, windshield wipers and washer, instruments, vent system, heater and accessories.	• At engine start-up.
• Check brake warning light operation.	• As required.
• Check operation of clutch.	• As required/at each fuel stop.
• Check engine oil level.	• Within 500 miles of either new vehicle delivery or any change of wheel.
• Check wheel nut torque.	

CY1503-A

F-500-700 B-, C-, L- and W-SERIES

NON-SCHEDULED MAINTENANCE

The following maintenance operations are not required at definite mileage or time intervals, but should be performed on an "as required" basis. Have your authorized dealer check these items when your truck's performance indicates the necessity.

MAINTENANCE OPERATION	WHEN PERFORMED
BODY	
• Clean Body/door drain holes.	• Improper water drainage is suspected.
• Replace windshield wiper elements. If washing the blades and the windshield with a cleanser does not restore a clean wipe.	• Blades do not clean glass.
• Lubricate door hinges, checks and hood hinges.	• High effort required to swing door or hood and audible squeaks.
ELECTRICAL	
• Check headlight alignment.	• Light beams in wrong position when operating loaded.
• Check windshield washer fluid level.	• Governed by weather conditions.
CHASSIS (b)	
• Adjust brakes – All.	• Insufficient power shown in loaded practice stop.
• Check operation of brakes, clutch and steering (e).	• Vehicle handling qualities not up to par.
• Check steering stop adjustment.	• Front wheels rub on undercarriage or sheet metal when turning.
• Adjust manual steering gear preload (all trucks) and change steering gear lubricant (a) (c).	• If excessive steering effort is experienced when operating at sustained extreme low ambient temperatures (d).
• Check front end alignment.	• Poor steering, wandering or excessive tire wear.
• Check parking brake adjustment.	• Will not hold on a reasonable grade.
• Check exhaust system for leaks and looseness – Correct.	• When system becomes noisy, is damaged or shows evidence of leaks.
• Check transmission and engine mountings.	• Hard shifting or excessive vibration.
• Check clutch and hydraulic brake master cylinders fluid level and brake pedal travel.	• Excessive pedal travel or spongy feet.
• Check wedge brake running clearance.	• Excessive pedal travel or slow brake action.
• Check wheel mounting nut torque	• Twice within first 500 miles and at first 1,000 miles.
• Inspect tires and check air pressure.	• Varies with operation.
• Balance wheels and tires.	• Vibration indicates unbalance.
• Rotate wheels and tires and torque lug nuts.	• Periodically to correct uneven tire wear and to prevent loose wheel lug nuts.
TRANSMISSION AND REAR AXLE	
• Check and adjust clutch pedal travel	• Insufficient free travel or hard shifting.
• Check and adjust transmission controls.	• Too much effort to shift or noisy transmission.
• Check clutch fluid level.	• Excessive pedal movement or sluggish action.
• Check Roadranger air filter for dirt or plugging.	• Sluggish transmission shift action.
• Drain water from transmission air filter.	• Governed by climate conditions and transmission action.
• Check torque tandem axle torque arm to brackets cap bolts.	• Vibration indicates looseness.
GASOLINE AND DIESEL ENGINES	
• Check fuel pump pressure and flow – Electric pump (gasoline engines).	• Insufficient full-throttle power or backfiring.
• Lubricate accelerator linkage EXCEPT BALL JOINTS AND PLASTIC BUSHINGS.	• Accelerator does not operate freely.
• Remove and clean radiator coolant level sightglass(es).	• When coolant level is difficult to see.
• Clean radiator cap seal.	• When cap does not hold pressure.
• Torque check engine mounting bolts, fan hub and drive pulley.	• Excessive engine vibration.

(a) Adjust center mesh preload to 2-5 in. lbs. above the minimum specified worm bearing preload. Perform the adjustment at a temperature of 50-75 degrees.

(b) During maintenance and repair, protect nylon tube fuel and air brake lines from external heat, acids, and abrasion that could damage the lines.

(c) Replace SAE 90 E.P. with SAE 80 E.P. hypoid gear lubricant – See Lubricant Specifications.

(d) During moderate temperatures, adjust center mesh preload to the currently published service Specifications and fill the gear with SAE 90 E.P. hypoid gear lubricant – See Lubrication Specification.

(e) Check for free clutch linkage action and make certain return spring force is adequate for maintaining pedal free play.

⑤ For complete refill of Dana limited-slip rear axles, add 2 ounces – Bronco or 4 ounces – Econoline and 100-350 Series Trucks EST-M2C118-A (friction modifier).

CY1168-D1

PART 50-04 Hoisting, Jacking and Towing

COMPONENT INDEX	Page	COMPONENT INDEX	Page
HOISTING		TOWING	
Bronco, Econoline and Light Trucks	04-01	Bronco	04-02
Medium and Heavy Trucks	04-01	Econoline	04-01
JACKING	04-01	F-100—F-350 P and M-Series Trucks	04-02
		500-750 and 6000-7000 Series Trucks	04-02
		800-900 and 8000-9000 Series Trucks	04-02

HOISTING

BRONCO, ECONOLINE AND LIGHT TRUCKS

Damage to suspension and/or steering linkage components may occur when positioning hoist adapters. Front end adapters should be positioned carefully to ensure maximum contact under the center of lower suspension arms or spring supports as near wheels as practical. Rear suspension hoist adapters (forks) should be placed under the spring mounting pads or rear axle housing, but the adapters must not interfere with shock absorber mounting brackets.

MEDIUM AND HEAVY TRUCKS

Hoist adapters for heavy duty hoists should be positioned according to the hoist manufacturers recommendations. Be sure the hoist has a adequate lifting capacity for the vehicle being lifted.

JACKING

GENERAL

CAUTION: On vehicles equipped with a limited-slip differential, do not run the engine with the vehicle on a jack.

When lifting a vehicle with the vehicle jack or any floor jack, block the diagonally opposite wheel to prevent vehicle from moving.

On Bronco, Econoline and light trucks, position vehicle and floor jacks under axles, radius arms or spring hangers as recommended in the vehicle owner's manual.

To raise heavy vehicles with floor jacks, follow the jack manufacturer's recommendations for placement of jack. Do not exceed the rated lift capacity of any jack.

TOWING

ECONOLINE

Make sure the parking brakes are released and the transmission gears are in neutral. It is important to know that the transmission and rear axle are in proper working order before pushing or towing. To move a vehicle with an inoperative axle, it is necessary to raise the rear wheels. If the transmission is inoperative, the drive shaft must be removed or the rear wheels raised, whichever is more convenient. When towing a vehicle with the rear wheels raised, install a locking device to hold the front wheels in a straight-ahead position.

Fasten the towing chains to the bumper brackets at the frame and route the chains under the bumper.

If the vehicle is being towed with the rear wheels on the ground, do not exceed 30 mph, or a distance of 15 miles. If this is not possible, it is advisable to tow the vehicle with the rear wheels raised off the ground, or with the drive shaft disconnected from the rear axle.

BRONCO

Check both front and rear axles for damage. If one axle is damaged, raise the damaged axle off the ground and tow backwards or forwards as described below. **If both axles are damaged, do not tow the vehicle unless a towing dolly is used.**

TOWING ON ALL FOUR WHEELS

1. Shift the transfer case and transmission to neutral position.
2. Disconnect the drive shaft from the rear axle, and tie it up.
3. If the front axle is equipped with free-running hubs, unlock the hubs. If the front axle is not equipped with free-running hubs, disconnect the drive shaft from the front axle and tie it up.

TOWING BACKWARD—REAR WHEELS OFF GROUND

1. Shift the transfer case and transmission to neutral position.
2. Install a locking device to hold the wheels in straight-ahead position.
3. If the vehicle is equipped with free-running hubs, unlock the hubs. If front axle is not equipped with free-running hubs, disconnect the drive shaft from the front axle and tie it up.

TOWING FORWARD—FRONT WHEELS OFF GROUND

1. Shift the transfer case and transmission to neutral position.
2. Disconnect the drive shaft from the rear axle and tie it up.

100-350 AND P-SERIES TRUCKS

STANDARD TRANSMISSION

Don't tow a truck equipped with a manual-shift transmission unless the drive shaft is disconnected (remove the front drive shaft or unlock free-running hubs on 4-wheel drive) since some gears may rotate, even in neutral gear, and lubrication may not be adequate.

When towing 4-wheel drive trucks backward with the rear wheels off the ground, the front wheels must be disconnected from the transmission. To do this, set the free-running hubs (if so equipped) to unlocked position. If the front axle is not equipped with free-running hubs, disconnect the forward drive shaft from the front axle and tie it up.

It is important that towing chains be fastened only to the arm or brackets that attach the bumper to the frame. The chains must be routed under the bottom edge of the bumper. Make sure the parking brake is released and the transmission is in neutral. It is important to know that the transmission and rear axle are in proper working order before towing. To move a truck with an inoperative rear axle, it is necessary to raise the rear wheels. If the transmission is inoperative, the drive shaft must be removed or the rear wheels raised.

If the vehicle is to be towed with the rear wheels raised, a locking device should be installed to hold the front wheels in a straight-ahead position.

AUTOMATIC TRANSMISSION

To tow a truck with automatic transmission less than 15 miles, place the selector lever at N. Be sure that the brakes are released. Don't tow at speeds faster than 30 mph with the rear wheels on the ground. If the truck must be towed more than 15 miles, or if the automatic transmission is inoperative, raise the rear wheels off the ground or disconnect the drive shaft from the axle.

500-750 AND 6000-7000 SERIES TRUCKS

Before towing, make sure the parking brakes are released and the transmission gears are in neutral. It is important to know that the transmission and rear axle are in proper working order before pushing or towing. To move a truck with an inoperative axle, it is necessary to raise the rear wheels. If the transmission is inoperative, the drive shaft must be removed or the rear wheels raised, whichever is more convenient. On 4-wheel drive trucks, the front drive shaft must be disconnected when towing from the rear with front wheels on the ground. **Remove rear axle shafts and seal ends of housing to prevent loss of axle lube before towing trucks with rear wheels on ground.**

For a truck equipped with automatic transmission, be sure that either the rear wheels are lifted off the ground, the driveline is disconnected, or the axle is pulled so that no transmission damage is incurred. Due to the transmission's hydraulic system, the engine cannot be started by pushing or towing.

800-900 AND 8000-9000 SERIES TRUCKS

Before towing, make sure the parking brakes are released and the transmission gears are in neutral. If air pressure is lost, release spring brakes manually. It is important to know that the transmission and rear axle(s) are in proper working order before pushing or towing. To move a truck with an inoperative axle, it is necessary to raise the rear wheels. If the transmission is inoperative, the drive shaft must be removed or the rear wheels raised, whichever is more convenient. **Remove rear axle shafts and seal ends of housing to prevent loss of axle lube before towing trucks with rear wheels on ground.** For a truck equipped with automatic transmission, be sure that either the rear wheels are lifted off the ground, the driveline is disconnected, or the axle is pulled so that no transmission damage is incurred. **Due to the transmission's hydraulic system, the engine cannot be started by pushing or towing.**

NOTE: After towing any tandem axle equipped truck, allow the vehicle to sit on a level surface until lubricant equalizes in both axles. Loss of lubricant may also have occurred during towing—so check lubricant level of power divider and both axles and refill if low.

PRE-DELIVERY

TORQUE WHEEL NUTS

It is important that wheel stud nuts and clamps be tightened alternately and evenly so that the lateral or side run-out of the wheel does not exceed one-eighth inch on front wheels or one-quarter inch on dual rear wheels.

On dual wheels, be sure to back off the outer nut before tightening the inner stud. Then tighten the outer nut. Some dual wheels are alternately flared inward and outward. These surfaces must be mated when the wheels are mounted.

Tighten all stud nuts to the recommended torque for the vehicle and wheel type (Refer to the Specifications).

WHEEL COVERS

Check for correct type of cover and install. Center the tire stem carefully in opening provided. Caution should be exercised when installing not to distort cover. Use rubber mallet on outer perimeter.

TIRE AIR PRESSURE

Check each tire to insure the air pressure agrees with those specified for the tire and vehicle model.

LUBRICATION

REPACK FRONT WHEEL BEARINGS

Sodium base grease is not compatible with lithium base grease and should not be intermixed. Therefore, do not lubricate front and/or rear wheel bearings without first ascertaining the type of original wheel bearing lubricant. Usage of incompatible bearing lubricants could result in premature lubricant breakdown.

If bearing adjustment will not eliminate looseness or rough and noisy operation, the hub and bearings should be cleaned, inspected, and repacked with specified wheel lubricant (Part 50-03). If the bearing cups or the cone and roller assemblies are worn or damaged, they should be replaced.

LIGHT VEHICLE

1. Raise the vehicle until the wheel and tire clear the floor and remove the wheel and tire from the hub. Remove the grease cap from the hub.
2. Remove the cotter pin, nut lock, adjusting nut and washer from the spindle (Fig. 1).
3. Remove the outer bearing cone and roller. Pull the hub and drum assembly off the wheel spindle. If the drum will not remove easily, back off the brake shoe adjusting screw so that the shoes do not contact the brake drum. Remove and discard the grease retainer. Remove the inner bearing cone and roller from the hub. **Remove all traces of old lubricant from bearings, hubs, and axle spindle.**
4. Inspect the cups for scratches, pits or cracks. If the cups are worn or damaged, remove them with a drift. Clean the inner and outer bearing cones and rollers with solvent and dry them thoroughly. **Do not spin the bearings dry with compressed air.**
5. Inspect the cones and rollers for cracks, nicks, brinelling, or seized rollers. Inspect the grease retainer and replace it if it is cracked, nicked, or dented. If the new grease retainer is leather, soak it in light engine oil for about 30 minutes before installation.
6. Cover the spindle with a clean cloth

and brush all loose dust and dirt from the brake assembly. **Remove the cloth from the spindle carefully to prevent dirt from falling on the spindle.**

7. Install the inner and outer bearing cups in the hub with the appropriate installing tool (Fig. 2). Be sure to seat the cups properly in the hub.

The cups will be properly seated when they are fully bottomed in the wheel hub. Pack the inside of the hub with the specified wheel bearing grease (Part 50-03). Fill the hub until the grease is flush with the inside diameters of both bearing cups. Pack the bearing cones and rollers with wheel bearing grease. Use a bearing packer for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.

8. Place the inner bearing cone and roller in the inner cup and install the grease retainer (Fig. 3) with the appropriate driving tool. Be sure that the retainer is fully bottomed. Install the hub and drum on the wheel spindle. Keep the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads.
9. Install the outer bearing cone and roller and the flat washer on the spindle, then install the adjusting nut.
10. Adjust the wheel bearing as outlined in this part.

F-100-F-350 DISC BRAKE EQUIPPED

The removal and installation of front wheel grease seals and bearings for disc brake equipped vehicles differs only in two respects from the procedure for drum brake equipped vehicles. First it is necessary to remove the brake caliper (refer to Group 12, Part 24). In this case the caliper can be suspended by wiring it above the hub and rotor. **Be careful not to twist or strain the flexible brake line.**

Then follow the procedure outlined for E-100-E-300 and P-350-P-500 with only one exception. A different tool T-73T-1190-B is required to install the special shielded grease seal. Finally install the brake caliper following the steps given in Group 12, Part 24 of Volume I.

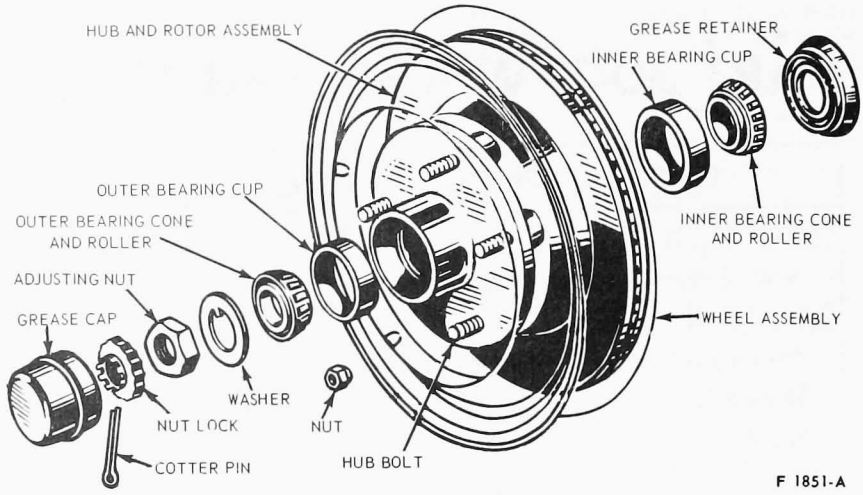

FIG. 1 Front Hub, Bearings and Grease Retainer—F-100 Through F-350

MEDIUM, HEAVY AND EXTRA HEAVY VEHICLES

There are two basic types of hubs, disc and cast (Fig. 4). The basic design of the hub bearings is the same in all hubs, but minor differences in size exist between the various models. The outer bearing attaching parts differ according to front axle weight capacity as indicated in Fig. 4.

1. Raise the vehicle until the tires clear the floor and install safety stands to support the front axle. Remove the grease cap and gasket from the hub.
2. To check the wheel bearing adjustment, alternately push inward and outward on the tire. If any excessive looseness is felt or there is no end play, adjustment of the front wheel bearings is necessary.
3. With 5000, 5500, 6000, 7000, 16000, 18000 or 20,000 pound capacity front axles, remove the cotter pin, adjusting nut and flat washer from the spindle. With 9000, 12000 or 15000 pound capacity front axles, remove the lock nut, washer, locking ring and the adjusting nut and pin. With a 12000 pound capacity center point front axle, remove the lock nut, inner washer, adjusting nut and outer washer.
4. Inspect the condition of the spindle and nut threads to insure a free running nut when reassembling.
5. Remove the outer bearing cone and roller. Pull the hub and drum assembly off the spindle. Remove

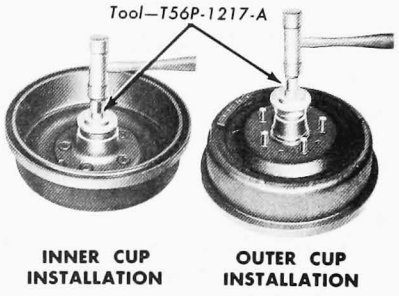

FIG. 2 Installing Bearing Cups—2-Wheel Drive

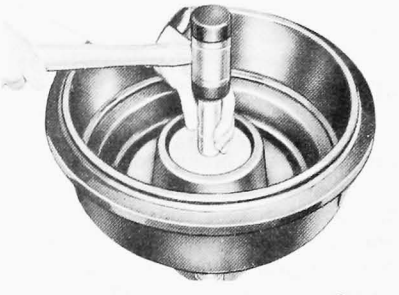

FIG. 3 Installing Grease Retainer

the inner bearing and seal using a brass drift. **Be careful not to damage the bearing cage.**

6. Remove all traces of old lubricant from the bearings, hubs and axle spindle. Inspect the cups for pitting, galling or unusual wear. If either cup is worn or damaged, remove it with a brass drift. Clean the inner and outer bearing cones and rollers with solvent and dry them thoroughly. **Do not spin the bearings dry with compressed air.**
7. Inspect the cones and rollers for pitting, galling or unusual wear. Particularly inspect the rollers for end wear and flat or rough spots. Replace all worn or damaged assemblies. It is recommended that the cone and roller assemblies and cups be replaced in sets.
8. Cover the spindle with a clean cloth and brush all loose dust and dirt from the brake assembly. Remove the cloth from the spindle carefully to prevent dirt falling on the spindle.
9. Install the inner and outer bearing cups in the hub with the appropriate tool (Fig. 5). Check for proper seating of the new bearing cups by trying to insert a 0.0015 inch feeler gauge between the cup and wheel hub. The feeler gauge should not enter.
10. Pack the inside of the hub with Lithium base wheel bearing grease (Part 50-03). Fill the hub until the grease is flush with the inside diameters of both bearing cups. Pack the bearing cones and rollers with wheel bearing grease. Use a bearing packer for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.
11. Place the inner bearing cone and roller in the inner cup and install a new grease retainer with the appropriate tool (Fig. 5). Be sure the retainer is fully bottomed. On all synthetic type seals, coat the seal lips with wheel bearing grease (Part 50-03) before installing the hub and drum. On seals which are not coated on the outside diameter with sealer by the supplier, coat the grease seal bore in the hub with a thin coat of non-hardening sealer prior to installing the grease seal.
12. Install the hub and drum on the wheel spindle. **Keep the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads.**
13. With 5000, 5500, 6000, 7000, 16,000, 18,000 or 20,000 pound capacity front axles, install the outer bearing cone and roller and the flat washer on the spindle. Then, install the adjusting nut. With 9000, 12,000 and 15,000 pound capacity front axles, install the outer bearing cone and roller and the bearing adjusting nut. With a 12,000 pound capacity center point front axle, install the washer and adjusting nut.

FIG. 5 Front Hub, Bearings and Grease Retainer

MAINTENANCE

TIRES AND AIR PRESSURES

Inspect the tire threads, and remove all stones, nails, glass or other objects that may be wedged in the thread grooves. Check for holes or cuts that may permit air leakage from the tire, and make the necessary repairs.

Inspect the tire side walls for cuts, bruises, and other damage. If internal damage to the tire is suspected, demount the tire from the wheel or rim for further inspection and repair or replacement.

Check the tire valve for air leaks, and replace the valve if necessary. If the valve cap is missing, install a new cap.

The tires should be checked frequently to insure the air pressure agrees with those specified for the tire and vehicle model.

ROTATE WHEELS AND TIRES

If wheels and tires are rotated, the spare tire should be included as shown in Fig. 6. On a vehicle with dual rear wheels, tire cross-switching is desirable but may not be possible when different size tires are used on the front and rear wheels.

Dual tires should be matched so that the tire diameters are within 1/4 inch of each other with the small diameter on the inner wheel to conform to the road. Tighten wheel stud nuts to specifications.

CHECK FRONT WHEEL BEARING ADJUSTMENT

Check the front wheel bearings for proper adjustment when the wheel is off the ground. Grasp the tire at the sides and alternately push inward and pull outward on the tire. If any looseness is felt, adjust the wheel bearing.

FRONT WHEEL BEARING ADJUSTMENT

F-100, 250, 350, ECONOLINE

1. Remove the hub cap and remove the grease cap from the hub.
2. Wipe any excess grease from the end of the spindle and remove the cotter pin and nut lock.
3. While rotating the wheel, torque the adjusting nut (Fig. 1) to 17-25 ft-lb to seat the bearings.
4. Install the nut lock so that the cotter pin hole in the spindle is aligned with a slot in the nut lock.
5. Back off the adjusting nut and nut lock two slots of the nut lock and install the cotter pin.
6. Check the front wheel rotation. If the wheel rotates freely with no noticeable end play, install the grease cap. If the wheel is still loose, or it rotates roughly or noisily, the bearing cones and rollers and the cups are dirty or worn and should be cleaned or replaced.
7. Install the hub cap.

P-350 THRU 500

1. Remove the hub cap, if so equipped, and remove the grease cap from the hub.
2. Remove any excess grease from the end of the spindle and remove the adjusting nut cotter pin.
3. While rotating the wheel, torque the adjusting nut (Fig. 5), to 40-55 ft-lbs to seat the bearings.
4. Back off the adjusting nut to the next castellation if necessary to align the nut with the cotter pin hole. Then, back off the adjusting nut two castellations and install the cotter pin.
5. Check the front wheel rotation. If the wheel rotates freely with no noticeable end play, install the grease cap. If the wheel is still loose, or it rotates roughly or noisily, the bearing cones and rollers and the cups are dirty or worn and should be cleaned or replaced.
6. Install the hub cap, if used.

ALL MEDIUM, HEAVY AND EXTRA HEAVY TRUCKS

Single Nut with Cotter Pin (5000-7000 Pound Front Axles)

1. While rotating the wheel, torque the adjusting nut to 70-100 ft-lb to seat the bearings.
2. Back off the adjusting nut 180 degrees (one half turn).
3. Hand tighten the adjusting nut finger tight (13-17 in-lb) while moving the top part of the tire in and out.
4. If the cotter pin hole lines up with a castellation in the nut, insert and secure a new cotter pin. If they do not line up, back off the adjusting nut to align a castellation with the first available cotter pin hole. Final bearing adjustment must provide .001-.010 end play.
5. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

Double Nut with Lock Ring (1500 Pound Front Axle)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lbs to seat the bearings.
2. Back off the adjusting nut one complete turn (Fig. 5).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 and .010 inch end play between the wheel hub and spindle.
5. Install the lock ring.
6. Install the washer with the dimple indexed in one of the holes in the locking ring.
7. Install the lock nut and torque to 100-125 ft-lb.
8. Recheck the end play (Final limit .001 to .010 inch). Re-adjust if necessary.
9. Bend the washer outward to lock the nut in position.
10. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

Double Nut with Double Washer (1200 Pound Center Point Axle)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearings.
2. Back off the adjusting nut one complete turn (Fig. 5).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 to .010 inch end play between the hub and spindle.
5. Install the outer washer and lock nut and torque to 100-125 ft-lb.
6. Recheck the end play (final limit .001 to .010 inch). Re-adjust if necessary.
7. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

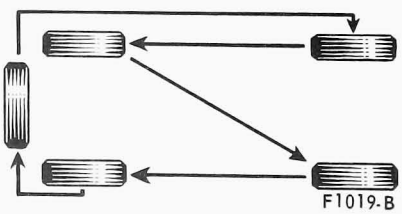

FIG. 6 Tire Cross Switching Diagram

Single Nut with Cotter Pin (16000, 18000 and 20000 Pound Front Axle)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearings.
2. Back off the adjusting nut one complete turn (Fig. 5).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut if necessary to align the nut castellations with the first available cotter pin hole.
5. Using the same cotter pin hole as a reference point, back off the adjusting nut **one additional castellation** to allow the wheel to rotate freely within the limits of .001 to .010 inch end play.
6. Insert and secure the cotter pin.
7. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

Double Nut with Lock Ring (9000 and 12000 Pound Front Axle)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearing.
2. Back off the adjusting nut one complete turn.
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 to .010 inch end play between the wheel hub and spindle.
5. Install the lock ring making sure the adjusting nut dowel is inserted into the lock ring.
6. Install the outer washer and lock nut. Torque to 100-150 ft-lb.
7. Recheck the end play (final limit .001 to .010 inch). Readjust if necessary.
8. Bend the washer outward to lock the outer nut in position.
9. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

TORQUE WHEEL NUTS

It is important that the wheel stud nuts and clamps be tightened alternately and evenly so that the lateral or side run-out of the wheel does not exceed one-eighth inch or front wheels or one-quarter inch on dual rear wheels.

On dual wheels, be sure to back off the outer nut before tightening the inner stud. Then tighten the outer nut. Some dual wheels are alternately flared inward and outward. These surfaces must be mated when the wheels are mounted.

Tighten all the stud nuts to the recommended torque for the vehicle and wheel type (refer to the Specifications).

WHEEL BALANCING

Refer to the instructions provided by the wheel balancer manufacturer.

Make certain that the brakes are not dragging, before attempting to spin the wheels.

SPECIFICATIONS

Refer to the 1973 Truck Shop Manual for any specifications or Special Tools not contained in this Section.

WHEEL NUT TORQUE LIMITS

Model	Nut Size	Ft-Lbs
E-100, E-200 F-100 (4 x 4) U-100 (Std. Wheel) F-250 (4 x 4) P-350, 3500 (W–5200 lb. Axle)	1/2–20	90

SPECIFICATIONS	12-11

PRE-DELIVERY

AIR PRESSURE BUZZER AND GAUGE OPERATION CHECK

Check operation. Operate brakes to drop pressure below 40 psi for test. With engine running, buzzer should sound and continue sounding until pressure builds up to 58-65 psi.

AIR COMPRESSOR GOVERNOR OPERATION CHECK

With engine running, the dash panel gauge should show governor cut-out at 118-126 psi, and cut-in at 98-104 psi. Adjust if required.

CHECK HYDRAULIC BRAKE MASTER CYLINDER FLUID LEVEL

The level should be maintained from full to 1/4 inch below the top of the reservoir on both single and dual master cylinders. Use only the specified brake fluid. Refer to the Lubricant Chart in Part 50-03.

HYDRAULIC BRAKE SYSTEM—CHECK BRAKE LINES AND FITTINGS

Check the brake lines and hoses for fluid leaks and/or loose connections. Inspect lines and hoses for kinks and interference with adjacent moving or frictional components. Check the brake booster and master cylinder for vacuum and fluid leaks. Tighten and correct as required.

AIR BRAKE SYSTEM—CHECK FITTINGS, CONNECTIONS, LINES AND COMPONENTS

Check for evidence of leakage at all fittings. Inspect lines for kinks and interference with adjacent moving or frictional components. Check for proximity to exhaust system. Tighten and correct as required. **CAUTION: During maintenance and repair, protect nylon tube air brake lines from external heat, acids and abrasion that could damage the lines.**

ADJUST BRAKES—SADDLE MOUNT DELIVERY

When a truck is delivered by saddle mount transportation, the rear wheel brakes must be adjusted at vehicle predelivery. This is necessary because the brakes are backed-off before a saddle mount delivery is made. Refer to the Maintenance Section of this part for adjustment procedures.

BRAKE OPERATION

Check and correct, as required, the following conditions: pull in either

direction, harshness or noise, excess pedal effort, or spongy feel. Avoid sudden hard stops—make slow, gradual stops, Check pedal height. On Econoline, F-100 and also F-250 when equipped with optional heavy duty brakes, it may be necessary to make a few reverse stops to fully adjust brakes.

PARKING BRAKE OPERATION

The parking brakes should be adjusted so that the vehicle will be held stationary on a reasonable grade when the parking brake control is fully applied.

LUBRICATION

LUBRICATE PARKING BRAKE CABLE AND LINKAGE

Raise the vehicle on a hoist, clean all old lubricant from the cable, and sparingly apply specified Speedometer Cable Grease (Part 50-03).

Lubricate all clevis pins and pivot points with SAE 10W engine oil.

LUBRICATE BRAKE PEDAL PIVOT SHAFT

On all except P-Series and air brake equipped vehicles, apply SAE 10W oil to the brake pedal shaft. On P-Series, apply the specified Chassis Lube with a pressure gun at the fitting.

LUBRICATE AIR BRAKE FOOT CONTROL VALVE

Lubricate the treadle pivots, roller and plunger face. Use only the specified lubricant recommended in Part 50-03.

MAINTENANCE

CHECK AND CLEAN AIR COMPRESSOR FILTER

Remove and disassemble the air inlet filter. If it is dirty and clogged, wash all parts, including the filter element, in a suitable cleaning solvent. Saturate the filter element with clean light engine oil and squeeze dry before placing it in the filter body. Assemble and install the filter.

CHECK AIR BRAKE AIR RESERVOIR

Check the connections to the air brake reservoir for leaks. Check to be sure the drain cock is closed and the reservoir is securely attached. Make any necessary corrections.

INSPECT BRAKE LININGS, BRAKE DRUMS, AND TORQUE BRAKE BACKING (CARRIER) PLATE ATTACHING BOLTS

1. Raise all four wheels. Remove one of the front brake drums, and inspect the drum and the linings (the wheel bearings should be inspected at this time and repacked if necessary). **Do not let oil or grease touch the drum or the linings.** If the linings are worn to within 1/32 inch of the rivet heads, replace or reline both sets (primary and secondary) on the front or rear wheels. **Do not replace one lining only, or one wheel set under any circumstances. Both front wheel sets or both rear wheel sets should be replaced whenever a respective lining or shoe is worn or damaged.** If the drum braking surface is excessively scored, refinish it. The condition of the remaining front linings is usually about the same as that of the one inspected. The rear brake linings may also need replacing at the same time.
2. Before relining a brake shoe, inspect the shoe for distortion, cracks, or looseness between the rim and web. If one of these conditions exists, replace the shoe. **Do not attempt to repair a damaged brake shoe.**
3. **On all truck series, be sure that the parking brake handle is fully released before making any brake adjustments.**
4. Check the front brake anchor pin nut with a wrench (on brake assemblies with an adjustable anchor pin). If the bolt is loose, tighten it to 80-100 ft-lbs torque.
5. Check the brake backing (carrier) plate attaching bolt torque. Torque to specifications.
6. With disc brakes, make a thickness measurement with a micrometer across the thinnest section of the shoe and lining. If the assembly has worn to a thickness of 0.231 inch (shoe and lining together) or 0.030 inch (lining material only) at any one of the three measuring locations or if lining shows evidence of brake fluid contamination, replace all (4) shoe and lining assemblies on both front wheels.

CLEAN FRAME MOUNTED VACUUM BOOSTER AIR CLEANER (P-SERIES EXCEPT P-350)

The air cleaner is mounted on the radiator support and connected to the booster by a hose. Disconnect the hose and remove the cleaner assembly. Wash the cleaner in a suitable solvent and saturate the filter element with SAE 10W engine oil. Mount the air cleaner on the radiator support and connect the hose.

REPLACE FRAME MOUNTED VACUUM BOOSTER AIR CLEANER— 500 THROUGH 900, EXCEPT C-SERIES

The air cleaner is mounted on the forward side of the dash panel on F-and B-600 through 750 cowl model trucks. On all other 500 through 900 except C- and P-Series trucks, the air cleaner is located in the cab behind the driver's seat. When the air cleaner becomes clogged and dirty, replace it with a new one.

CLEAN AND REFILL FRAME MOUNTED VACUUM BOOSTER OIL BATH AIR CLEANER—C-SERIES WITH SPLIT HYDRAULIC BRAKES

On C-Series models, an oil bath air cleaner is mounted on a rear frame crossmember cylinder (Fig. 1). To service the air cleaner element, grasp the lower housing and unscrew it from the air cleaner cover. Slide the filter element, housing and sleeve assembly off the center bolt. Drain the fluid from the lower housing and remove the baffle plate. No further disassembly should be attempted. Rinse the filter element, housing and the sleeve assembly in clean isopropyl alcohol. Rinse the baffle plate and the inside of the lower housing with the same solvent. Use an air hose to blow dirt out of the lower housing. **Do not use an air hose on the filter element.** If the filter element is too dirty to clean, replace the element, housing and the sleeve as an assembly. Use a cloth dampened with isopropyl alcohol to wipe the inside of the air cleaner cover and the hose nipple. If the gasket in the cover is loose, cement it securely to the cover with Permatex No. 1. If it is damaged, replace the gasket. Insert the baffle plate, legs first, in the lower housing and fill to the level indicated with DSTZ-19577-A (ESA-M97B23-B) oil. Slide the filter assembly onto the center bolt in the lower housing and screw the center bolt into the cover. Hand tighten the lower housing.

CLEAN INTERNAL EXPANDING SHOE PARKING BRAKE (WITHOUT DUST SHIELD)

Remove the universal joint assembly and drive shaft from the parking brake drum. Remove the drum from the transmission. Clean the dirt and dust from the brake shoes and drum with a scraper and air hose. Install the brake drum and connect the universal joint and drive shaft.

ADJUST HYDRAULIC BRAKES

The brake drums should be at normal room temperature, when the brake shoes are adjusted. If the shoes are adjusted when the drums are hot and expanded, the shoes may drag as the drums cool and contract.

A minor brake adjustment re-establishes the brake lining-to-drum clearance and compensates for normal lining wear.

A major brake adjustment includes the adjustment of the brake shoe anchor pins, if so equipped, as well as the brake shoes. Adjustment of the anchor pin permits the centering of the brake shoes in the drum.

Adjustment procedures for each type of brake assembly are given under the applicable heading.

SELF ADJUSTING BRAKES—F-100-350, E-100-300, P-350 AND BRONCO

The brake shoes are automatically adjusted when the truck is driven in reverse and the brakes applied. A manual adjustment is required only after the brake shoes have been relined or replaced. **The manual adjustment is performed while the drums are removed, using the tool and the procedure detailed below.**

When adjusting the rear brake shoes, check the parking brake cables for proper adjustment. Make sure that the equalizer operates freely.

To adjust the brake shoes:

1. Use Rotunda Tool HRE 8650, (Fig. 2) and adjust to the inside diameter of the drum braking surface.
2. Reverse the tool as shown in Fig. 3 and adjust the brake shoes to touch the gauge. **The gauge contact points on the shoes (Fig. 3) must be parallel to the vehicle with the center line through the center of the axle. Hold the automatic adjusting lever out of engagement while rotating the adjusting screw, to prevent burring the screw slots. Make sure the adjusting screw rotates freely. If necessary, lubricate the adjusting screw threads with a thin, uniform coating of C1AZ-19590-B Grease.**
3. Apply a small quantity of C1AZ-19590-B high temperature grease to the points where the shoes contact the carrier plate, being careful not to get the lubricant on the linings.
4. Install the drums. Install the retaining nuts and tighten securely.
5. Install the wheels on the drums and tighten the mounting nuts to specification.
6. Complete the adjustment by applying the brakes several times while backing the vehicle.
7. After the brake shoes have been properly adjusted, check the operation of the brakes by making several stops while operating in a forward direction.

FRONT BRAKE—P-500

The single anchor brake is adjusted by turning an adjusting screw located between the lower ends of the shoes.

1. Raise the vehicle until the wheels clear the floor.
2. Remove the cover from the adjusting hole at the bottom of the brake carrier plate, and turn adjusting screw inside the hole to expand the brake shoes until they drag against the brake drum and lock up the drum. Back off the adjusting screw until a slight drag is noted (Fig. 4).
3. When the shoes are against the drum, back off the adjusting screw 10 to 12 notches so that the drum rotates freely without drag. If the

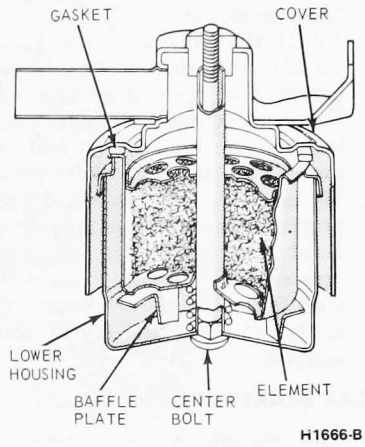

FIG. 1 Booster Air Filter—C-Series with Bendix Dual Diaphragm Booster

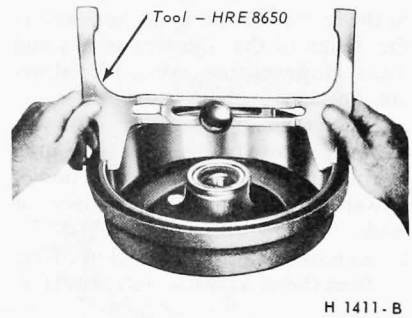

FIG. 2 Measuring Drum

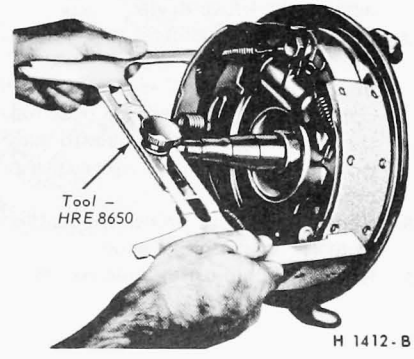

FIG. 3 Measuring Shoes

drum does not rotate freely, remove the wheel and drum, and then blow out the dust and dirt from the linings. With sandpaper, remove all rust from the points where the shoes contact the carrier plate and apply a light coating of grease (C1AZ-19590-B). Be careful not to get the lubricant on the linings.

4. Install the wheel and drum, and adjust the shoes. Install the adjusting hole cover on the brake backing (carrier) plate.
5. Check and adjust the other three brake assemblies.
6. Apply the brakes. If the pedal travels more than halfway down between the released position and the floor, too much clearance exists between the brake shoes and the drums. Repeat steps 2 and 3 above.
7. When all brake shoes have been properly adjusted, lower the vehicle. Road test the vehicle and check the operation of the brakes. Perform the road test only when the brakes will apply and the vehicle can be safely stopped.

REAR BRAKES—P-500

The two-cylinder brake assembly brake shoes are adjusted by turning adjusting wheels reached through slots in the backing (carrier) plate.

Two types of two-cylinder brake assemblies are used on truck rear wheels. The assemblies differ primarily in the retracting spring hookup, and in the design of the adjusting screws and locks. However, the service procedures are the same for both assemblies.

The brake adjustment is made with the vehicle raised. Check the brake drag by rotating the drum in the direction of forward rotation as the adjustment is made.

1. Remove the adjusting slot covers from the backing (carrier) plate (Fig. 5).
2. Turn the rear (secondary shoe) adjusting screw inside the hole to expand the brake shoe until it drags against the brake drum.
3. Back off the adjusting screw so that the drum rotates freely without drag. Depress the brake pedal to center the brake shoes, and back off the adjusting screw an additional notch to provide operating clearance.
4. Repeat the above procedure on the front (primary) brake shoe.
5. Replace the adjusting hole covers.

SELF ADJUSTING BRAKES—REAR—500-900 SERIES (EXCEPT P-500)

The brake shoes are automatically adjusted when the vehicle is driven in reverse and the brakes applied. A manual adjustment is required only after the brake shoes have been relined or replaced.

The two-cylinder brake assembly (Figs. 6 and 7) brake shoes are adjusted by turning adjusting wheels reached through slots in the backing plate.

Two types of two-cylinder brake assemblies are used on truck rear wheels. The assemblies differ primarily in the retracting spring hookup, and in the design of the adjusting screws and locks. However, the service procedures are the same for both assemblies.

The brake adjustment is made with the vehicle raised. Check the brake drag by rotating the drum in the direction of forward rotation as the adjustment is made.

1. Remove the adjusting slot covers from the backing (carrier) plate (Fig. 5).
2. Turn the rear (secondary shoe) adjusting screw inside the hole to expand the brake shoe until a slight drag is felt against the brake drum.
3. Repeat the above procedure on the front (primary) brake shoe.
4. Replace the adjusting hole covers.
5. Complete the adjustment by applying the brakes several times while backing the vehicle.
6. After the brake shoes have been properly adjusted, check the operation of the brakes by making several stops while operating in a forward direction.

SELF ADJUSTING BRAKES—TWO-CYLINDER FRONT 600-900 SERIES

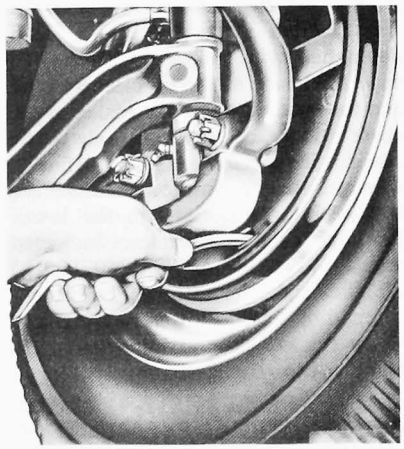
Two-cylinder front brakes are adjusted by means of exposed, hex-head, self-locking cam adjusters. The brakes are to be manually adjusted initially. Subsequent adjustment is automatic. To adjust this brake:

1. Raise the vehicle and check the front brakes for drag by rotating the wheels.
2. Adjust one shoe by rotating the wheel backward and forward while turning the cam hex-head with a wrench. Bring the shoe out to the drum until a light drag is felt. **Do not apply excessive force on the hex-head cam, as automatic adjuster parts can be damaged.** Back off the adjustment until the wheel turns freely. Adjust the other cam on the same wheel in the same manner.
3. Adjust the other front wheel brake using the procedure above.
4. Apply the brakes and recheck the adjustment.

SELF ADJUSTING BRAKES—ONE-CYLINDER FRONT 500-800 SERIES (EXCEPT P-500)

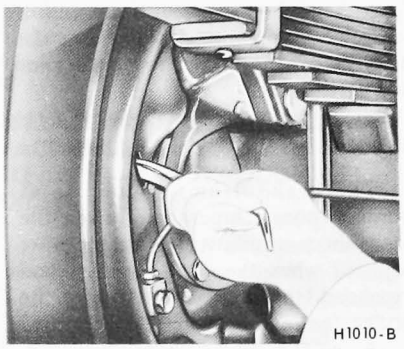
The brake shoes are automatically adjusted when the vehicle is driven in reverse and the brakes applied. A manual adjustment is required only after the brake shoes have been relined or replaced.

1. With the vehicle raised, check the front brakes for drag by rotating the wheels.



H1006-B

FIG. 4 Single Anchor Brake Shoe Adjustment



H1010-B

FIG. 5 Two-Cylinder Brake (Rear) Shoe Adjustment

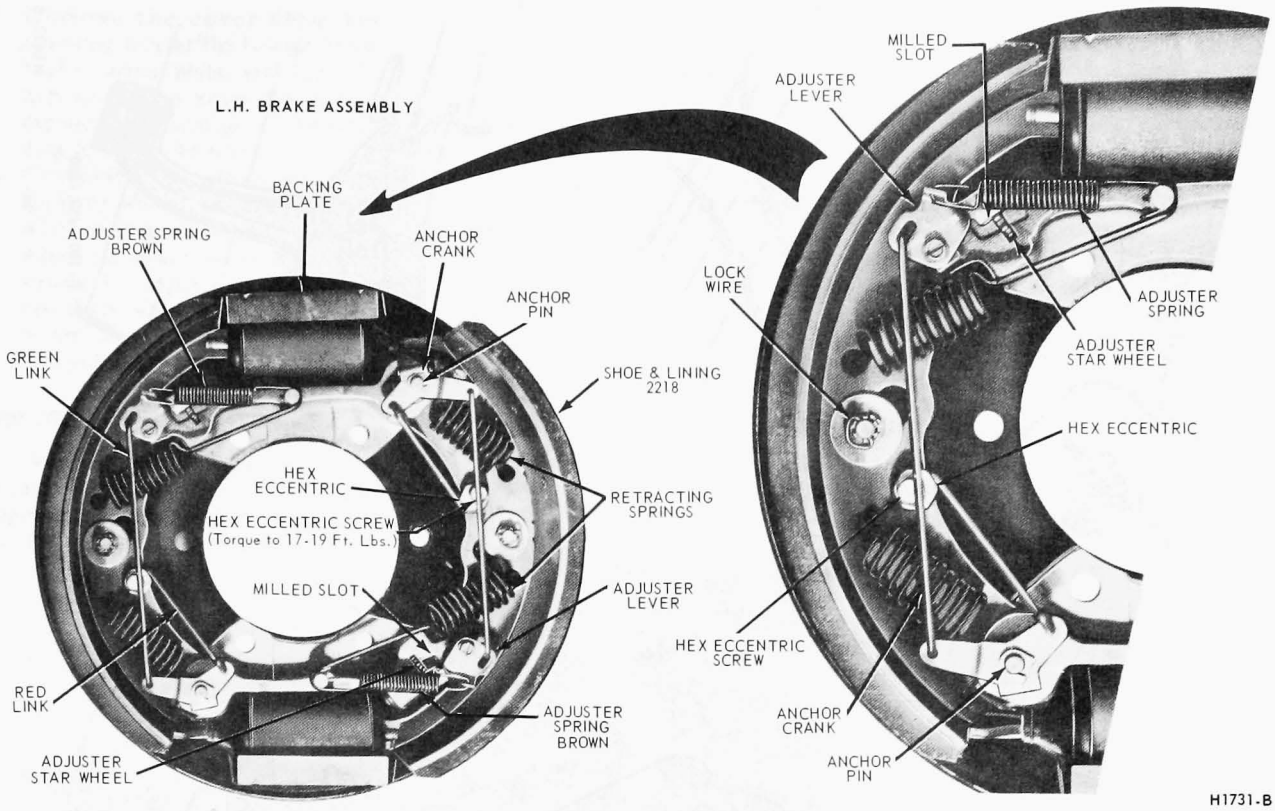


FIG. 6 Two-Cylinder Brake Shoe—Rear (Wagner)

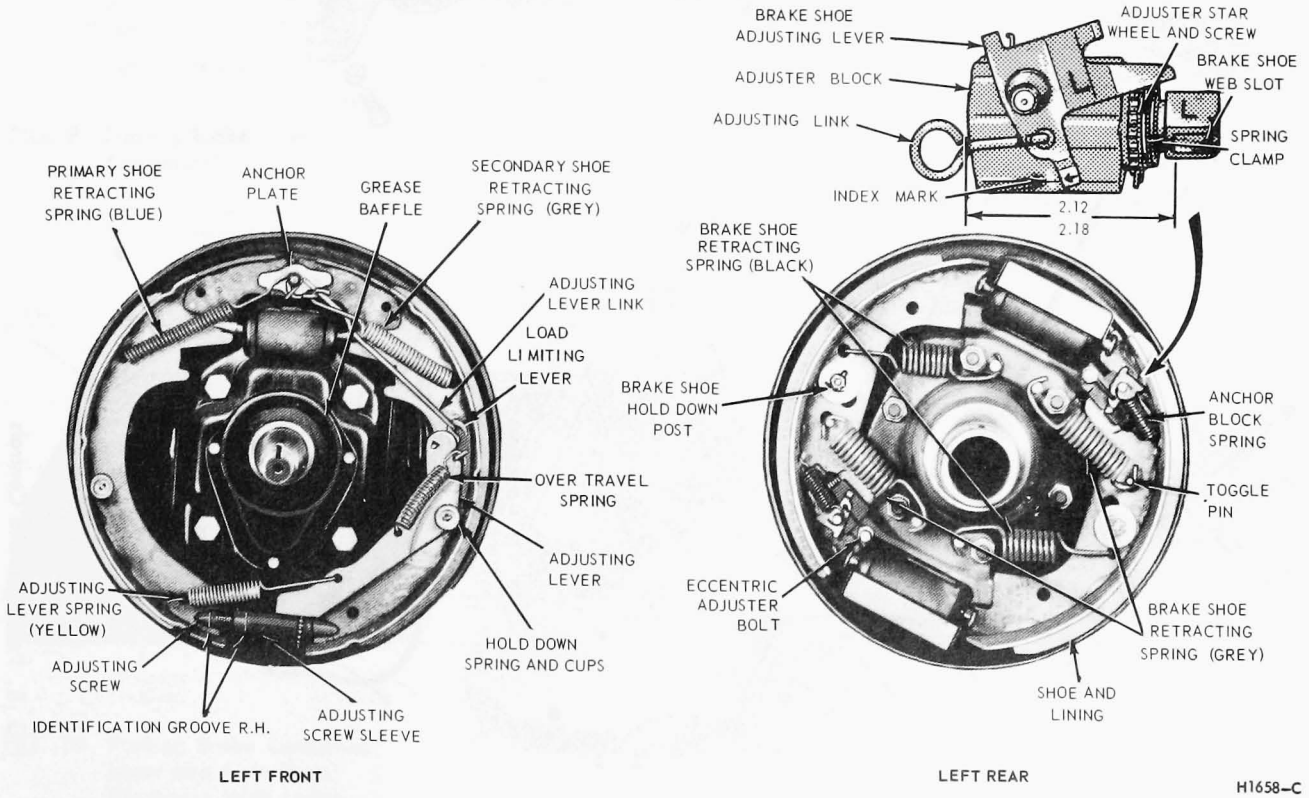

FIG. 7 Kelsey Hayes Hydraulic Brake Assemblies—Front and Rear

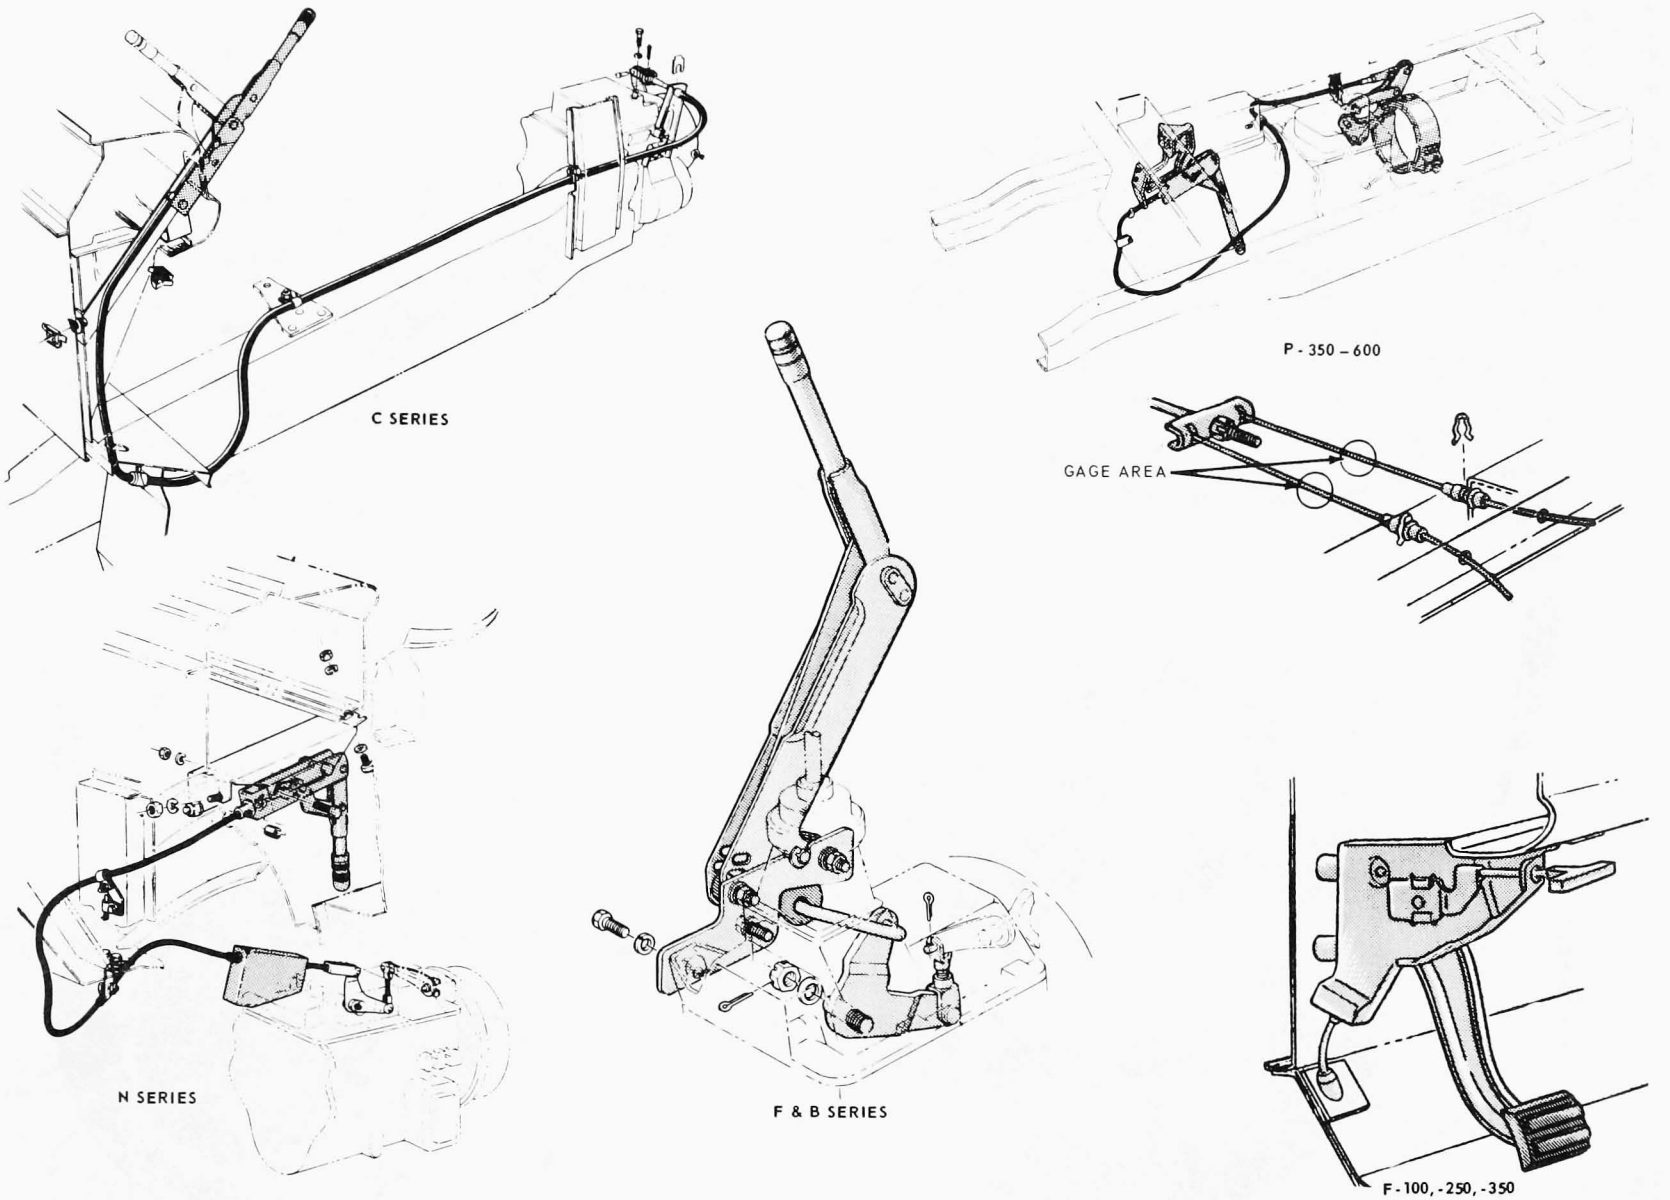

FIG. 8 Parking Brake Controls

2. Remove the cover from the adjusting hole at the bottom of the brake carrier plate, and turn the adjusting screw inside the hole to expand the brake shoes until a slight drag is felt at the wheel.
3. Complete the adjustment by applying the brakes several times while backing the vehicle.
4. After the brake shoes have been properly adjusted, check the operation of the brakes by making several stops while operating in a forward direction.

AIR BRAKES—ADJUSTMENT

Wedge-type air brakes are self adjusting. For service of automatic adjuster assemblies refer to Group 12 of the 1973 Truck Shop Manual.

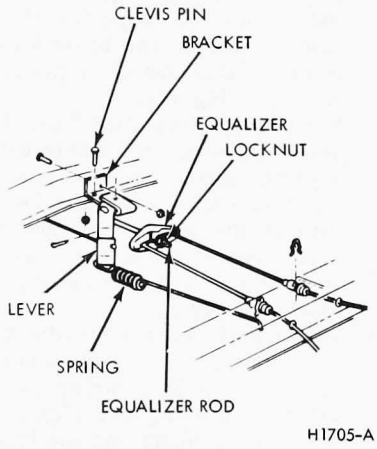

FIG. 9 Parking Brake Cable Adjustment

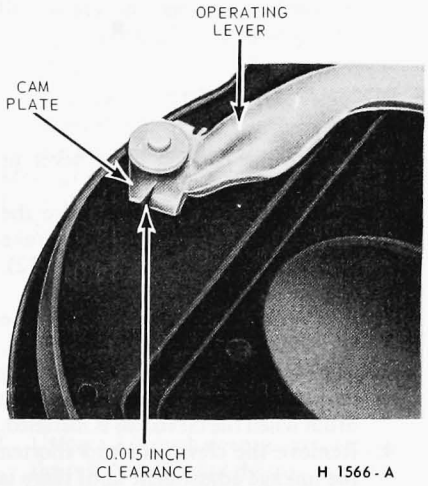

FIG. 10 Parking Brake Operating Lever and Cam Plate Clearance Web Ledge Brakes

Check wedge-type air brake shoe running clearance by inserting feeler gauge between shoe and drum at access hole.

Bendix.....0.040 inch
Rockwell.....0.060 inch

A preliminary adjustment can be made by rotating the wheels in a forward direction and applying air to the brake chambers 25 to 30 times.

Check cam-type air brake slack adjuster travel and adjust if necessary (see Specifications).

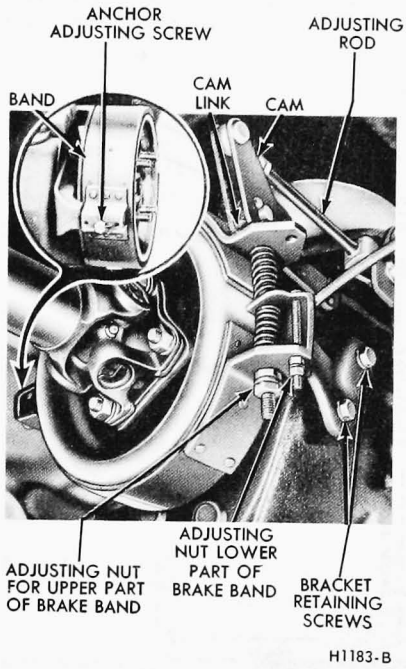

FIG. 11 External Band Type Parking Brake

AIR BRAKE SERVICE

For air brake chamber service procedures, refer to the following parts of the 1973 Truck Shop Manual (Volume 1, Group 12—Brakes):

PARKING BRAKE ADJUSTMENT

VEHICLES EQUIPPED WITH ORSCHELN LEVER

The Orscheln parking brake (Fig. 8) is the over center locking type. It is adjusted (while in the released position) by turning the lever knob. When properly adjusted, it pulls over center with a distinct click. No other adjustment is normally required.

CABLE ACTUATED TYPE

Adjust the service brakes before attempting to adjust the parking brake cables.

Place the parking brake lever in the fully released position, then check for slack in the parking brake two rear cables (Fig. 9).

The cables should be tight enough to provide full application of the rear brake shoes, when the parking brake lever or foot pedal is placed in the fully applied position, yet loose enough to ensure complete release of the brake shoes when the lever is in the released position.

If the cables are loose, adjust them as follows:

1. Set the parking brake control handle (if applicable) in the fully applied position. On F-100, F-250, F-350 and Bronco models, set the foot pedal at two notches or clicks.
2. Attach a brake cable tension gauge to the brake cables behind the equalizer as indicated in Fig. 8.

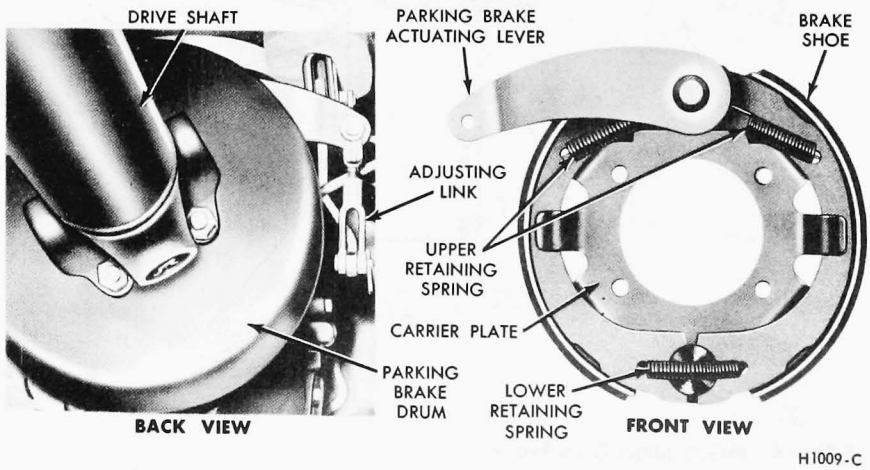

FIG. 12 Transmission Mounted Internal Shoe Type Parking Brake—9 Inch

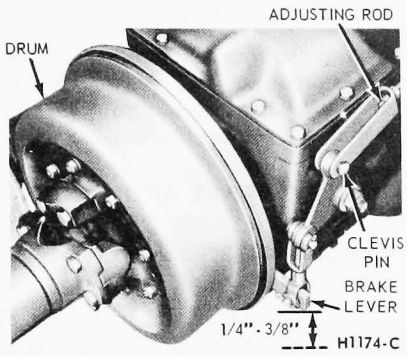

FIG. 13 Shoe-Type Parking Brake—Twelve Inch Drum

3. Loosen the lock nut and tighten the adjusting nut against the equalizer until the specified cable tension is obtained. Release and reset the cable tension gauge to make certain the specified cable tension has been obtained (see Specifications).

The cable tensions **must** be taken on **both rear cables** on the E-100, E-200 and E-300 models and on the **left rear cable only** for F-100, F-250, F-350, and Bronco models.

4. When the cables are properly adjusted, tighten the lock nut against the equalizer.
5. If rear wheel brake drag is noted after adjustment on F-250, F-350, E-300, models equipped with web ledge brakes, the rear drums must be removed after the service and parking brakes have been adjusted. Check the clearance between the parking brake lever and the cam plate (Fig. 10). The clearance should be 0.015 inch with the brakes fully released. If the clearance is not within specifications, readjust the parking brake cable.

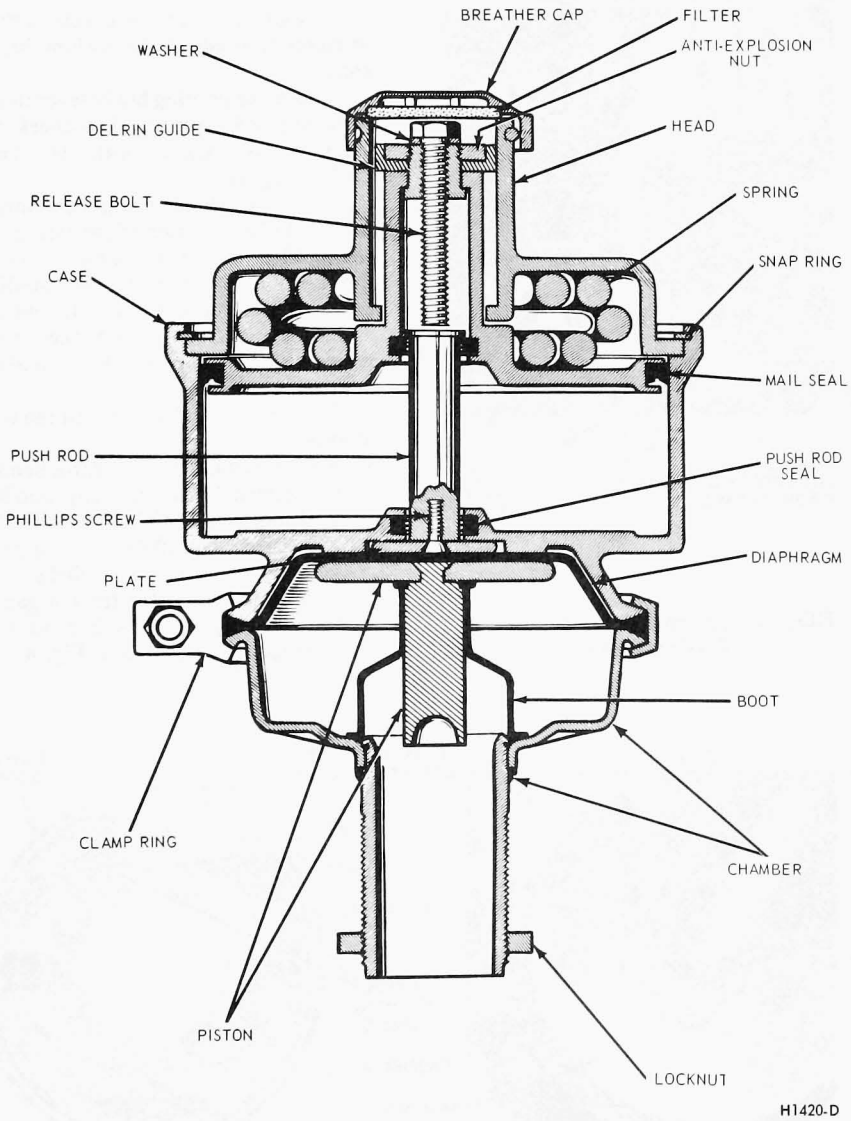

FIG. 14 MGM Short Stop Brake

EXTERNAL BAND TYPE

1. On cable-controlled parking brakes (Fig. 11), move the parking brake lever to the fully released position. On a vehicle with a rod-type linkage, set the lever at the first notch.
2. Check the position of the cam to make sure the flat portion is resting on the brake band bracket. If the cam is not flat with the bracket, remove the clevis pin from the upper part of the cam, and adjust the clevis rod to allow the flat portion of the cam to rest on the brake band bracket. Install the clevis pin and cotter pin (Fig. 11).
3. Remove the lock wire from the anchor adjusting screw, and turn the adjusting screw clockwise until a clearance of 0.010 inch is established between the brake lining and the brake drum at the anchor bracket. Install the lock wire in the anchor adjusting screw.
4. Loosen the lock nut on the adjusting screw for the lower half of the brake band, and adjust the screw to establish a 0.010 inch clearance between the lining and the brake drum at the lower half of the brake band (Fig. 11). Tighten the lock nut.
5. Turn the upper band adjusting rod nut until a 0.010 inch clearance is established between the upper half of the band and the drum.

INTERNAL SHOE TYPE

Nine-Inch Diameter Drum

1. Release the parking brake lever in the cab.
2. From under the truck, remove the cotter pin from the parking brake linkage adjusting clevis pin (Fig. 12). Remove the clevis pin.
3. Lengthen the parking brake adjusting link by turning the clevis. Continue to lengthen the adjusting link until the shoes seat against the drum when the clevis pin is installed.
4. Remove the clevis pin and shorten the linkage adjustment until there is 0.010 inch clearance between the shoes and the drum. The measurement should be taken at all

points around the drum with the clevis pin installed.
5. Install a new cotter pin in the clevis retaining pin and check the brake operation.

Twelve-Inch Diameter Drum

There is no internal adjustment on this brake. Adjustment is made on the linkage. Remove the clevis pin, loosen the nuts on the adjusting rod, and turn the clevis on the rod until a 1/4-3/8 inch free play is obtained at the brake lever (Fig. 13). Tighten the nuts, and connect the clevis to the bellcrank with the clevis pin.

SPRING BRAKE MANUAL RELEASE

MGM SHORT STOP

If air pressure fails in the Shortstop piston chamber, the power spring applies the brakes, and, unless pressure can be re-established, the brakes must be released as follows in order to move the truck:

1. (See Fig. 14) Remove the bolt and nut holding the cap and filter to the housing and remove the cap and filter.
2. Using a 9/16 inch deep-socket wrench, unscrew the release bolt until it turns freely. The brake shoe pressure is now released. Follow this procedure until all Shortstop units are released.
3. When air pressure has been restored, screw the release bolt in until the lock washer holds it securely. This MUST be done to regain Shortstop protection.

MGM LOW-PROFILE

Manual Release

1. Block the wheels to prevent vehicle from moving.
2. Using a 3/4 inch deep socket, unscrew the release bolt (Fig. 15) approximately 1 3/4 inches. **Do not use an air impact wrench.**

Manual Reset

1. If the breather cover and filter are loose, make certain the four (4) notched holes in the breather cover are 180 degrees opposite the two (2) breather holes in the cylinder housing and that the breather cover is centered on the cylinder housing assembly. Tighten the breather cover retaining screws.
2. Using a 3/4 inch deep socket, screw the release bolt until the nut securely butts the flat washer against the breather cover. **Torque the drive nut 30-35 in-lbs. Do not overtorque the nut or use an air impact wrench since this will damage the assembly.**

MGM STOPGARD

1. TO RELEASE: Block the wheels to prevent the vehicle from moving.
2. Remove (unscrew) the breather cap.
3. Using a 15/16 inch wrench, unscrew the release bolt (Fig. 16) approximately 30 turns until the brake shoes release from the drum. If the release bolt binds, apply rust penetrant (COAZ-19A501-A) or equivalent and allow it to soak into the threads.
4. TO RESET: If the release bolt threads are dry, coat the bolt with chassis lubricant. Screw the release bolt down into the unit until the nut bottoms against the case. Torque the nut to 50 ft-lbs.

MAXIBRAKE MANUAL RELEASE

1. Disconnect air hoses from spring brake port of the chamber (Fig. 17).
2. Install Schrader valves in chambers.

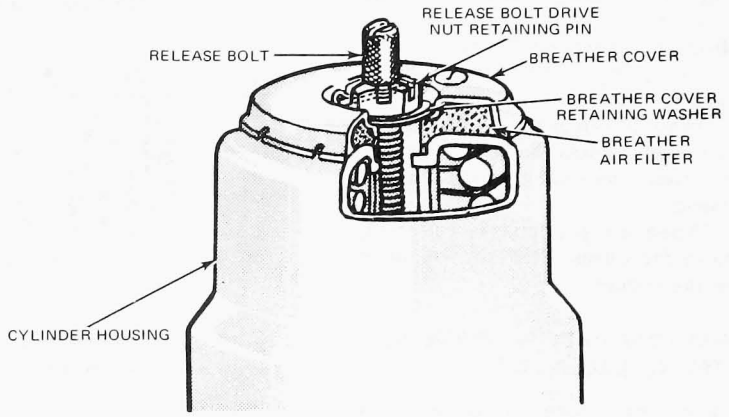

FIG. 15 MGM Low-Profile Brake

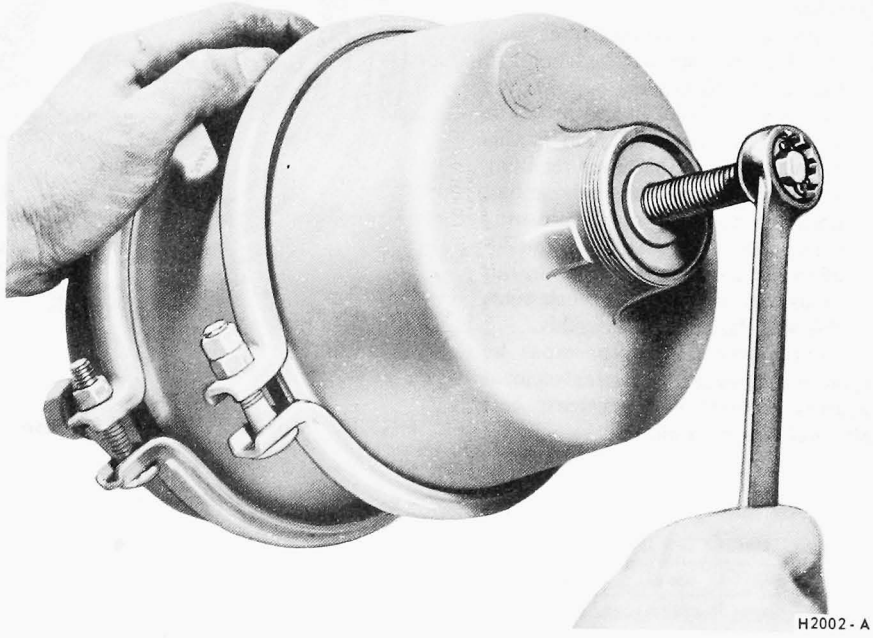

FIG. 16 MGM Stopgard Parking (Spring) Brake Manual Release

3. Charge chambers with air from outside source.
4. Remove Schrader valves and reconnect all lines.

ANCHORLOK SERVICE AND PARKING BRAKE

Remove the release stud tool and nut from the carrying pocket on the brake chamber assembly. Remove the access plug from the end of the spring chamber (Fig. 18). Insert the release stud through the opening in the chamber and into the spring pressure plate. Turn the release stud 1/4 turn to engage the stud tangs with the slot in the pressure plate. Keep the stud engaged and install the nut on the release stud until the spring is fully caged and the brakes are released.

Do not loosen or remove the release stud and nut unless the brake chamber is completely assembled and is securely clamped.

When air pressure is restored, remove the release stud and install in carrying pocket.

MGM LOW-PROFILE BRAKE AIR FILTER REPLACEMENT

1. Build up system air pressure to governor cut-out to insure full compression of the parking-emergency spring.
2. Using a 3/4 inch deep socket wrench, unscrew the release bolt approximately 1 inch.
3. Remove the breather cover retaining screw and remove the cover.
4. Remove breather filter by carefully stretching it over the cover.

Installation

1. Install a new or cleaned filter.
2. Position the four notched holes in the cover 180 degrees opposite the two breather holes in the top of the housing cylinder, and hold in this position. Install the cover retaining screw; then, install the release bolt until the nut and washer are snug against the cover. **Torque the nut 30-35 in-lbs. Do not overtorque the nut or use an air impact wrench since this will damage the assembly.**

The filter and cover must be replaced if damaged. Cover replacement requires removal of the release bolt drive nut retaining pin.

MGM SHORT STOP BRAKE AIR FILTER REPLACEMENT

Unscrew bolt and nut securing breather cap to chamber head. Remove breather cap and discard filter. Clean breather cap, install a new filter, and reassemble cap to chamber head.

BRAKE PEDAL FREE TRAVEL—HYDRAULIC BRAKES

On dual-brake master cylinder or dash-mounted vacuum booster equipped vehicles, the brake systems are designed to permit full stroke of the master cylinder when the brake pedal is fully depressed. A brake pedal clearance adjustment is not required.

In order to release the brakes, fluid in a hydraulic brake system must flow back to the master cylinder when pedal pressure is released. A port is provided in the master cylinder to allow this flow, but the piston must move back far enough to expose the return port. To be sure that this will always happen, free-travel is built into the pedal linkage on single master cylinders with non-power brakes or frame-mounted booster systems. This free-travel prevents the piston from becoming trapped in a partially released position. Pedal free travel is not always perceptible in dash-mounted booster systems, however, because the operating clearance for the piston is adjusted at the booster push rod, rather than the pedal linkage (Refer to Volume 1, Group 12 of the 1973 Truck Shop Manual for instructions on dash-mounted booster push rod adjustments).

Pedal free travel is not adjustable on 500-1000 Series trucks with a dash-mounted booster and a single or dual system or units with a dual system and a frame-mounted booster.

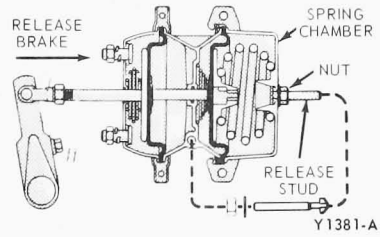

FIG. 18 Anchorlok Service and Parking Brake

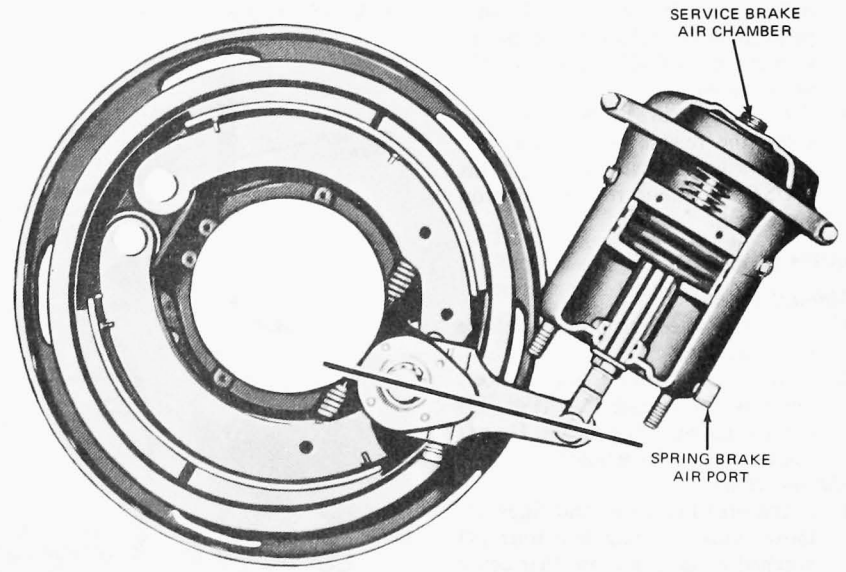

FIG. 17 Maxibrake Manual Release

SPECIFICATIONS

Refer to the 1973 Truck Shop Manual for any specifications or Special Tools not contained in this Section.

SPECIFIC TORQUE LIMITS

Front Brake Backing Plate to Spindle (100–400 Series)	1/2 x 13, 55-70	7/16 x 14, 30–50	1/2 x 20, 55–75
Front Brake Backing Plate and Steering Arm to Spindle (100–400 Series)	1/2 x 13, 30–40	1/2 x 20, 50–70	
Rear Backing Plate to Axle (100–400 Series)	1/2 x 13, 75–105	1/2 x 20, 50–70	7/16 x 14, 35–45
Brake Assembly to Front Axle (500–900 Series)	9/16 x 12, 110–150	1/2 x 13, 75–105	1/2 x 20, 75–105
Brake Assembly to Rear Axle (500–900 Series)	9/16 x 12, 110–150	1/2 x 13, 75–105	1/2 x 20, 75–105
Brake Drum to Hub Nuts or Bolts (500–900 Series)	1/2 x 13, 68–85	5/8 x 18, 136–170	
Master Cylinder or Booster Push Rod to Brake Pedal (500–900 Series)	3/8 x 16, 12–17		
Master Cylinder to Dash Panel (500–900 Series)	5/16 x 18, 12–17	3/8 x 16, 31–42	
Master Cylinder to Booster (Dash Mounted Booster) (500–700 Series)	14–18		
Booster to Dash Panel (Dash Mounted Booster) (500–700 Series)	3/8 x 16, 12–17	3/8 x 24, 13–20	5/16 x 18, 12–15
Master Cylinder to Pedal Bracket	5/16 x 24, 12–15	3/8 x 24, 12–17	
Eccentric Adjuster Bolt Torque	80–120 inch lbs.		

TORQUE LIMITS – HYDRAULIC TUBE NUTS (FT-LBS)

Thread Size	Ft-Lbs. ①	Thread Size	Ft-Lbs. ①
3/8–24	8–15	1/2–20	12–17
7/16–24	12–17	9/16–18	15–25

① All hydraulic line connections (nuts) must be torqued to the specified value and free of fluid leakage.

BRAKE DRUM REPAIR LIMITS (BRAKE LATHE)

Brake drums are marked with the maximum allowable braking surface diameter. If this diameter is exceeded by wear or refinishing, the drum must be replaced.

S-CAM BRAKE ADJUSTMENT TABLE

Brake Chamber Type	Maximum Stroke at Which Brake Should Be Adjusted ①	Maximum Stroke After Adjustment ①
Front – Type no. 9	1 3/8 inch	1.00 Inch
no. 12	1 3/8 Inch	1.00 Inch
no. 16	1 3/8 Inch	1.00 Inch
Rear – Type no. 24	1 3/4 Inch	1 1/4 Inch
no. 30	2.00 Inch	1 1/4 Inch

① Push rod stroke is measured from chamber or chamber mounting bracket to Push rod clevis.

AIR SUPPLY SYSTEM

Air Brake System Pressure Settings	
Safety Valve Setting (Air Pressure)	150 PSI
Warning Buzzer Operating Pressure	60 PSI or Less
Cut-Out Pressure (Governor)	118–126 PSI
Cut-In Pressure (Governor)	98–104 PSI

Torque Limits (Ft-Lbs)	
Air Brake Compressor Pulley Nut②	3/4, 40–45

② Advance nut to next cotter pin slot, if necessary, to Install Cotter Pin.

AIR BRAKE LINE TYPES

SAE J844 Type 3A – For 1/4 Inch

SAE J844 Type 3B – For 3/8, 1/2, 3/4 Inch

NYLON HOSE TUBE NUT TORQUE

Size	Torque	Size	Torque
7/16–24	85–115 In.Lbs.	11/16–20	12–17 Ft-Lbs.
17/32–24	12–17 Ft-Lbs.	1–18	20–29 Ft-Lbs.

PARKING BRAKE CABLE TENSION ADJUSTMENT

Model	Cable Tension ①	
	New ②	Used ③
F-100-250 (4 x 2)	160-200 lbs.	115-200 lbs.
F-250-350 with Web Ledge Brakes & F-250 4 x 4	80-120 lbs.	65-120 lbs.
E-100-200	285-325 lbs.	275-325 lbs.
E-300	210-250 lbs.	200-250 lbs.
Bronco	130-170 lbs.	115-155 lbs.

① With hand lever full on or with foot control pedal set at two notches or clicks.
② With new linings and/or new cable.
③ Whenever readjustment is required.

PRE-DELIVERY

VISUALLY CHECK STEERING

Inspect the steering for proper assembly and components. Check to assure that all lock tabs and cotter pins are properly installed.

STEERING CONTROL AND POWER STEERING

Check steering wheel return from both directions. Test for steering effort required and inconsistent effort in different directions. Check for harshness noise, wander or free play. Correct as required.

CHECK STEERING MOUNTINGS, LINKAGE AND CONNECTIONS

Check the steering gear attaching bolts to be sure they are tightened to specifications. Torque the attaching bolts to specifications if necessary.

Check the linkage for tightness and proper installation of cotter pins. correct as required.

CHECK POWER STEERING LINES

Check the linkage for tightness and proper installation of cotter pins. Correct as required.

CHECK POWER STEERING RESERVOIR FLUID LEVEL

Run the engine until the fluid is at normal operating temperature. Then turn the steering wheel all the way to the left and right several times. Make sure that the wheels are in the straight-ahead position, then shut off the engine.

Check the fluid level in the power steering reservoir on Ford-Thompson pumps. The level must show on the cross hatching between the bottom of the dipstick and the full mark. If the level is low, add fluid. Refer to the Lubricants Chart in Part 50-03 for the fluid specification number. **Do not overfill the reservoir.** Remove excess fluid with a suction device.

LUBRICATION

LUBRICATE STEERING LINKAGE

Apply the specified Chassis lubricant (Part 50-03) with a pressure gun at all fittings on the linkage.

LUBRICATE STEERING SHAFT SLIP SPLINE (W-SERIES)

Apply pressure gun grease to the grease fitting (Fig. 1) until the grease appears at the spline end. Refer to Part 50-03, Lubricants Chart, for the recommended lubricant.

LUBRICATE STEERING COLUMN U-JOINTS (C-, LN-AND W-SERIES)

Apply Ford Chassis Lubricant to the U-joint fittings, using a pressure gun. Refer to Part 50-03 for lubricant specifications.

CHECK STEERING GEAR LUBRICANT LEVEL

F-100, F-250 AND 350 (4 X 2) SERIES MANUAL STEERING

1. Center the steering wheel.
2. Remove the steering gear housing filler plug.
3. Remove the lower cover-to-housing attaching bolt.
4. With a clean punch or like instrument, clean out or push the loose lubricant in the filler plug hole and cover-to-housing attaching bolt hole inward.
5. Slowly turn the steering wheel to the left until linkage reaches stop. Lubricant should rise within the cover lower bolt hole; then slowly turn the steering wheel to the right until linkage reaches stop. Lubricant should rise within the filler plug hole. If lubricant does not rise in both the cover bolt hole and the filler plug hole, add specified lubricant until it comes out both holes during this check.
6. Install the lower cover-to-housing attaching bolt and the filler plug.

ECONOLINE

1. Remove the steering gear housing filler plug.
2. With a clean punch or like instrument, clean out or push the loose lubricant into the filler plug hole. Turn the steering wheel to the **left.** Then turn the steering wheel slowly to the **right** until linkage reaches stop. Lubricant should rise in the filler plug hole. If lubricant does not rise in the filler plug hole, add specified lubricant.

The location of the steering gear does not allow clearance for the removal of a cover bolt for creating a vent. To prevent air from being trapped and forming pockets in the housing while lubricant is being added, it is suggested that a curved length of 1/4 inch tubing be adapted to the end of the grease gun being used. This tube should be inserted into the filler hole and extend down toward the bottom of the housing cavity. By this method, the lower housing cavity will fill first and as lubricant is added, air will be expelled upward and out the filler hole.

To add lubricant, turn the steering wheel to the extreme **left** to position the ball nut away from the filler plug hole and fill gear by method described above until lubricant rises in the filler plug hole.

F-100 4-WHEEL DRIVE AND BRONCO

1. Remove the filler plug from the sector shaft cover.
2. Check to see if the lubricant level is visible in the filler plug-tower. If the lubricant is visible, install the filler plug. If the lubricant is not visible, add specified lubricant (Part 50-03) as outlined in Step 3.

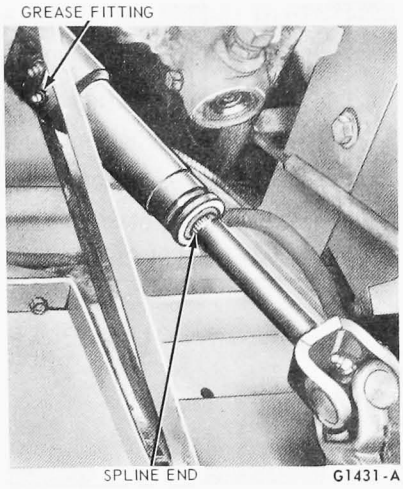

FIG. 1 Steering Shaft Slip Spline—W-Series

3. Add steering gear lubricant until the lubricant level is visible approximately 1 inch from the top of the hole in the filler plug tower; then, install the filler plug.

500 THRU 900 SERIES, F-250 (4 X 4) AND P-SERIES WITH MANUAL STEERING

1. Remove the filler plug from the top of the steering gear housing.
2. Check the lubricant level. If the level is to the bottom of the filler plug opening, install the filler plug. If the level is not to the bottom of the filler plug hole, add fluid to raise the level to that level. **Do not use a pressure gun as it could damage the seals in the gear.**

ROSS SEMI-INTEGRAL POWER STEERING GEAR—W-SERIES

1. Remove the upper most filler plug from the gear housing.
2. Install a 90 degree, 3/8 inch street pipe elbow in the filler plug hole of the gear as shown in Fig. 2.
3. Add specified lubricant (Part 50-03) into the open end of the elbow until the lubricant is visible.
4. Install the plug, removed in step 1, in the street elbow.

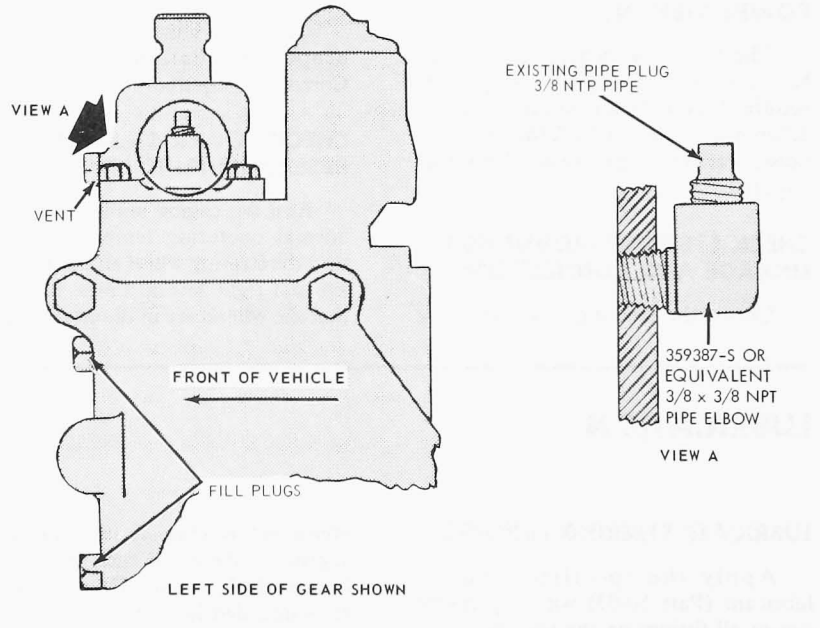

FIG. 2 Ross HPS-70 Steering Gear Lubricant Fill—W-Series

MAINTENANCE

CHECK STEERING STOP ADJUSTMENTS

TWIN-I-BEAM AXLE

The steering stops are not adjustable on Twin-I-Beam front axles.

ALL EXCEPT TWIN-I-BEAM AXLES

To avoid tire and/or steering linkage damage, the steering stop adjustments should be checked periodically, and adjusted if necessary.

Fig. 3 shows the position of the front wheels when checking the stop adjustment angles shown in the specification charts at the end of this Part.

Manual, Integral or Semi-Integral Power Steering Gear

The following spindle stop adjustment is the only one required:

1. Raise the front of the vehicle until the wheels clear the floor.
2. Set spindle stop bolts to obtain specified angle.

Linkage Type Power Steering Gear

1. Raise both front wheels off the ground by jacking under the axle.
2. Screw both Pitman arm stop bolts (Fig. 4) away from the Pitman arm to prevent contact with the Pitman arm prior to the spindle stops contacting the axle.
3. Start the engine and adjust each spindle stop to obtain the specified turn angle.
4. When the wheel is at each stop, screw the Pitman arm stop bolt in to contact the Pitman arm.
5. Return the wheels to straight-ahead position, then turn each Pitman arm stop bolt two turns toward the Pitman arm. Tighten each Pitman arm stop bolt lock nut.

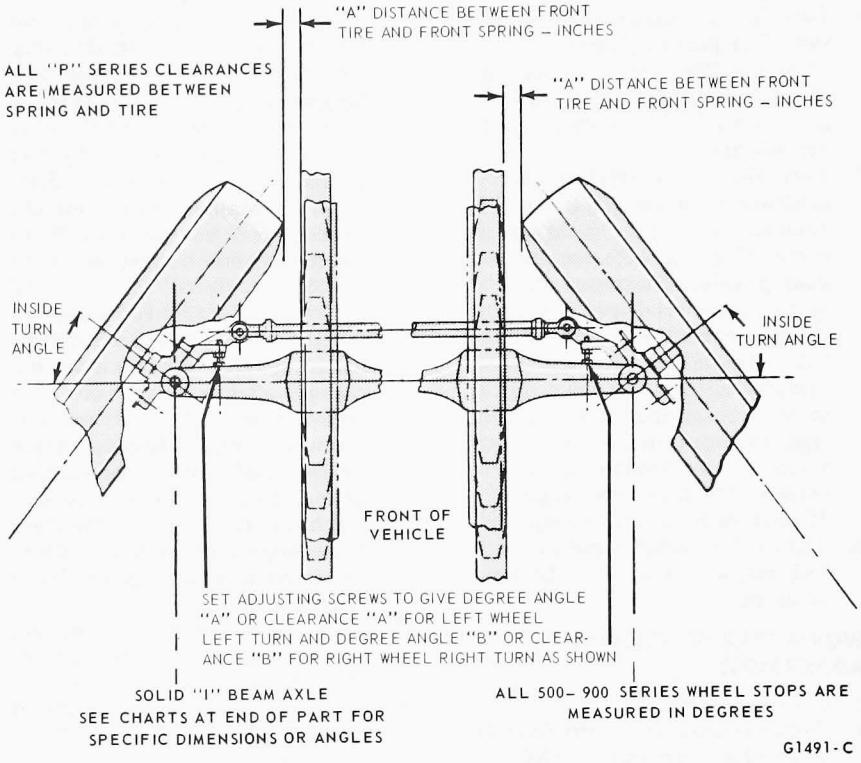

FIG. 3 Spindle Arm Stop Adjustment—All Except Twin-I-Beam Vehicles

STEERING GEAR ADJUSTMENTS

WORM BEARING PRELOAD ADJUSTMENT—F-100-350 (4 X 2)

Correctly adjusted worm bearing preload will help to eliminate excessive steering shaft and worm end play. **Always check the worn bearing preload before checking and adjusting the worm and roller mesh. The worm and roller mesh should always be checked and adjusted after checking and adjusting the worm bearing preload.**

1. Remove the Pitman arm from the steering gear sector shaft.
2. Disconnect the horn wire at the horn relay. Remove the horn button and spring from the steering wheel.
3. Turn the steering wheel to the end of its travel.
4. Place an in-lb torque wrench on the steering wheel nut (Fig. 5). Measure the lowest torque required to turn the wheel at a constant speed. The lowest torque reading is the worm bearing preload. If the torque (preload) is not within specification adjust as described in step 5.
5. Loosen the steering shaft bearing adjuster lock nut and tighten or loosen the bearing adjuster (Fig. 6) to bring the preload to specifications. Tighten the steering shaft bearing adjuster lock nut and recheck the preload.

STEERING WORM AND SECTOR GEAR ADJUSTMENT—ECONOLINE

The steering gear must be removed from the vehicle to properly make a preload and mesh load adjustment. Therefore, it should be determined that the steering column is aligned properly and not causing excessive turning effort before attempting to adjust the gear.

The ball nut assembly and the sector gear must be adjusted properly to maintain minimum steering shaft end play (a factor of preload adjustment) and minimum backlash between sector gear and ball nut. There are only two possible adjustments within the recirculating ball-type steering gear, and **these should be made in the following order to avoid damage or gear failure.**

1. Loosen the nut which locks the sector shaft adjusting screw (Fig. 7) and turn the adjusting screw counterclockwise approximately three turns.
2. Measure the worm bearing preload by attaching an in-lb torque wrench to the input shaft (Fig. 8). Read the torque required to rotate the input shaft approximately 1 1/2 turns either side of center. If the torque or preload is not within specifications, adjust the steering gear as explained in the next step.

3. Loosen the worm bearing adjuster lock nut, and tighten or back off the bearing adjuster (Fig. 7) to bring the preload within the specified limits. Tighten the lock nut and recheck the preload.
4. Turn the input shaft slowly to either stop. **Turn gently against the stop to avoid possible damage to the ball return guides.** Then rotate the shaft approximately three turns to center the ball nut.
5. Turn the sector adjusting screw clockwise until the specified pull is obtained to rotate the worm past its center (Fig. 8). With the steering gear position on center and the sector shaft retained to prevent rotation, check the lash between the ball nuts, balls and worm shaft by applying a 15 in-lb torque on the steering gear input shaft, in both right and left turn directions. Total travel of the wrench should not exceed 1 1/4 inches when applying a 15 in-lb torque on the steering shaft.
6. Tighten the sector adjusting screw lock nut, and recheck the backlash adjustment.

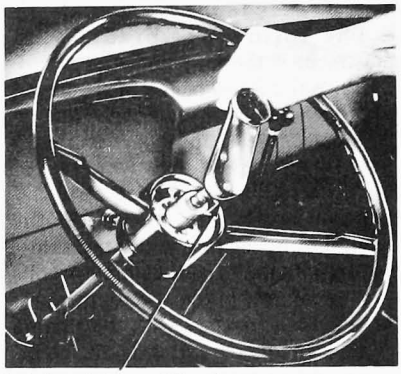
WORM BEARING PRELOAD ADJUSTMENT

F-100 4-Wheel Drive

1. Disconnect the Pitman arm from the sector shaft with T64P-3590-F.
2. Disconnect the wire socket at the horn relay. Remove the horn button and spring.
3. Turn the steering wheel to the end of its travel in either direction.
4. Place an in-lb torque wrench on the steering wheel retaining nut, and measure the torque required to keep the wheel moving at a constant rate for approximately 1/4 to 1/2 turn. If the torque, or preload is not within specifications, remove or add gasket shims between the worm shaft bearing retainer cover and the steering gear housing (Fig. 9) to adjust the worm bearing preload to specification. Install the cover and torque the attaching bolts to specification. Then, recheck the worm preload to be sure it has not changed after the cover bolts have been tightened. **If erratic readings are experienced, disconnect the steering shaft joint at the steering gear. Then, check the torque required to rotate the steering shaft. If the torque is measurable, add it to the worm bearing preload specification.**
5. After adjusting the worm preload, turn the gear to the other end of its travel and recheck the preload.
6. Check the steering gear lubricant level and add lubricant as necessary (Part 50-03).

Bronco

1. Remove the steering gear as described in Group 13 of the 1973 Truck Shop Manual.
2. Loosen the mesh and roller adjusting lock nut. Back off adjusting screw 2-3 turns.
3. Place an in-lb torque wrench on the input shaft. Check the torque required to rotate the input shaft 1 1/2 turns either side of center. If the torque or preload is not within specifications, remove or add gasket shims between the worm shaft bearing retainer cover and the steering gear housing (Fig. 9) to adjust the worm bearing preload to specification.
4. Tighten the mesh and roller adjusting screw 2-3 turns and perform the worm and roller mesh adjustment.



Inch-Pounds Torque Wrench

G1564-A

FIG. 5 Checking Steering Gear Preload

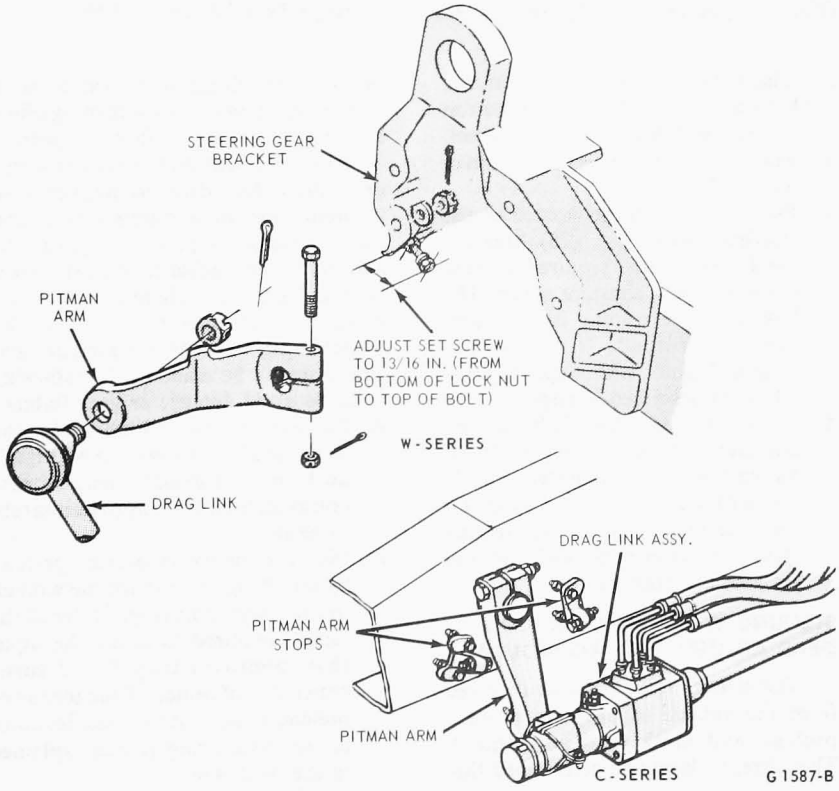


FIG. 4 Pitman Arm Stops—W-and C-Series

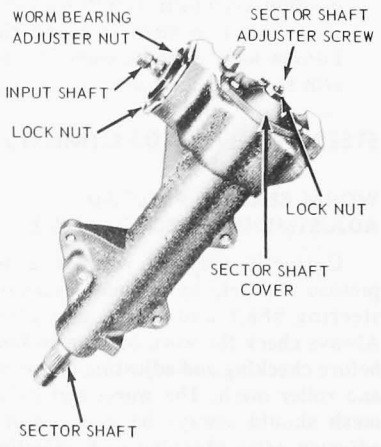

G1563-A

FIG. 6 Manual Steering Gear—Recirculating Ball—F-100 thru F-350 (2-Wheel Drive)

5. Install the steering gear as described in the 1973 Truck Shop Manual.
6. Check the steering gear lubricant level and add lubricant as necessary (Part 50-03).

F-BL-W-C-500-9000

1. Remove the steering gear from the vehicle. Refer to Group 13 of the 1973 Truck Shop Manual.
2. Place a 12 point, 13/16 inch socket on the lower steering shaft serrations. Attach an in-lb torque wrench to the socket and turn the steering gear at a constant speed. The lowest torque required is the worm bearing preload. If the torque is not within specification, make the adjustment as outlined in step 3.
3. To adjust the worm bearing preload, remove or add gasket shims between the worm shaft bearing retainer (Fig. 10) to bring the worm bearing preload to the proper specifications. Install the cover and torque to specifications.
4. Adjust the worm and roller mesh preload.
5. Install the steering gear in the vehicle.

WORM AND ROLLER MESH ADJUSTMENT

All Except F-100-350 (4 x 2) and Econoline (Manual Steering)

The worm bearing preload should always be checked and adjusted, if necessary, before the worm and roller mesh is checked and adjusted.

1. Remove the steering gear from the vehicle.
2. Place an in-lb torque wrench on the steering gear input shaft (Fig. 11). Measure the torque required to turn the steering wheel through the straight-ahead (high point) position. The highest torque reading is the worm and roller mesh preload. If the preload is not within specification adjust as outlined in steps 3 through 5.
3. To adjust the mesh, loosen the adjusting screw lock nut on the side of the steering gear housing and adjust the worm and roller mesh, or by turning it outward (counterclockwise) to loosen the mesh.
4. After adjusting the mesh, hold the adjusting screw stationary with a screwdriver and tighten the lock nut.
5. Recheck the mesh adjustment. If the mesh is still not correct, repeat the adjustment procedure.
6. Install the steering gear and fill it to the correct level with the specified lubricant.

FORD INTEGRAL POWER STEERING GEAR ADJUSTMENT

The only adjustment which can be performed is the total over center position load, to eliminate excessive lash between the sector and rack teeth.

1. Disconnect the Pitman arm from the sector shaft.
2. Disconnect the fluid return line at the reservoir, at the same time cap the reservoir return line pipe.
3. Place the end of the return line in a clean container and cycle the steering wheel in both directions as required, to discharge the fluid from the gear.
4. Turn the steering wheel to 45 degrees from the left stop.
5. Using an in-lb torque wrench on the steering wheel nut, determine the torque required to rotate the shaft slowly through an approximately 1/8 turn from the 45 degree position.
6. Turn the steering gear back to center, then determine the torque required to rotate the shaft back and forth across the center position. Loosen the adjuster nut, and turn the adjuster screw (Fig. 12) until the reading is 11-12 in-lb greater than

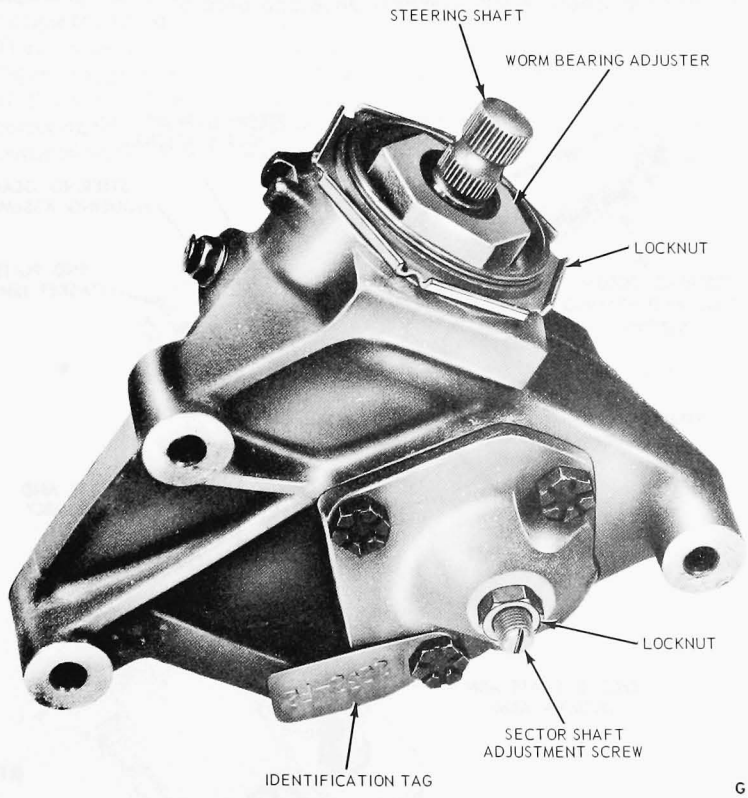

FIG. 7 Manual Steering Gear—Recirculating Ball— Econoline

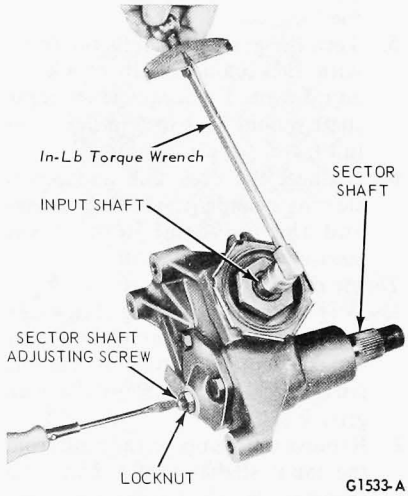

FIG. 8 Setting Mesh Load—Econoline

the torque 45 degrees from the stop. Tighten the lock nut while holding the screw in place.

7. Recheck the readings and replace the Pitman arm and the steering wheel hub cover.
8. Connect the fluid return line to the reservoir and fill the reservoir with specified lubricant to the proper level.

Do not pry against the reservoir to obtain proper belt load as it can be deformed and cause a leak.

9. Recheck the belt tension. When the tension has been correctly adjusted, tighten the bolts and the nut to 30-40 ft-lbs torque.

ROSS HPS-70 SEMI-INTEGRAL

Mesh Adjustment

This adjustment must be made through the mid-position to the high spot. **Do not adjust the mesh adjustment in any position except the straight-ahead position. Backlash is normal when the steering gear cam is in the end position, (wheels turned to one side).**

1. Disconnect the drag link and power steering cylinder from the Pitman arm and the universal joint from the gear input shaft.
2. Loosen the adjusting screw lock nut. Then, turn the adjusting screw (Fig. 13) clockwise until a 15 in-lb torque is required to turn the steering gear through the mid-position.
3. Back out (counterclockwise) the adjusting screw 1/8 turn.
4. Tighten the adjusting screw lock nut to 15-20 ft-lb torque to lock the adjustment. Be sure the adjusting screw does not turn when tightening the lock nut.
5. Turn the gear through its full travel with the engine off to check the adjustment. The torque at the input shaft should be 2 to 8 in-lb for the full travel (stop to stop).
6. Connect the drag link and power steering cylinder to the Pitman arm and the universal joint to the steering gear input shaft.

Thrust Bearing Adjustment

1. With the steering linkage disconnected, turn the steering gear off the center position to free the stud roller bearing from the cam groove.
2. Remove the clamp bolt and nut from the input shaft (cam) U-joint and separate the joint from the input shaft.
3. Remove four upper cover attaching

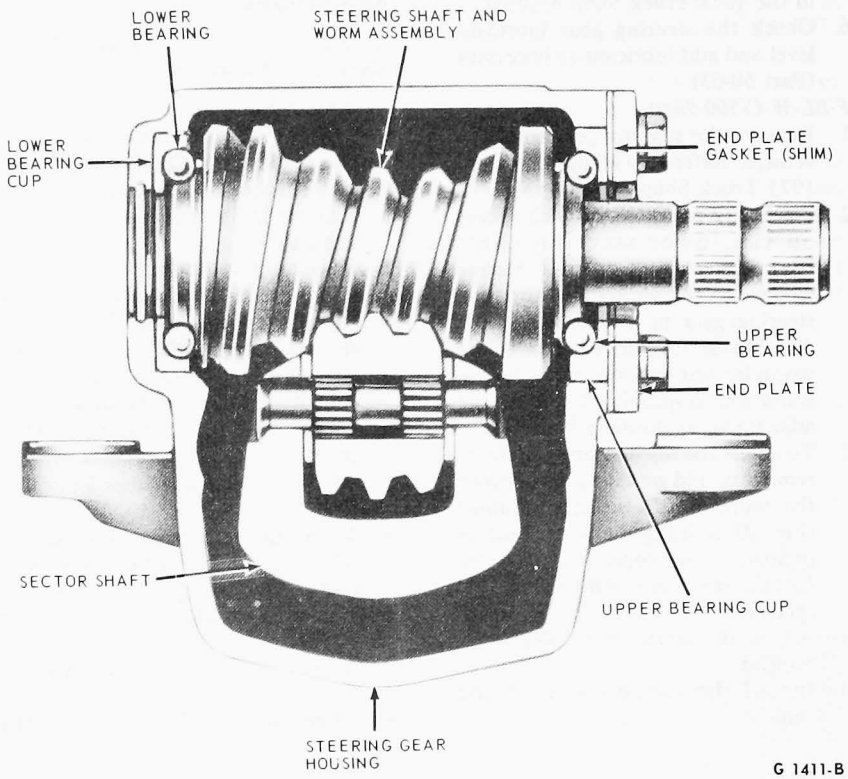

FIG. 9 Steering Gear—F-100 4-Wheel Drive and Bronco

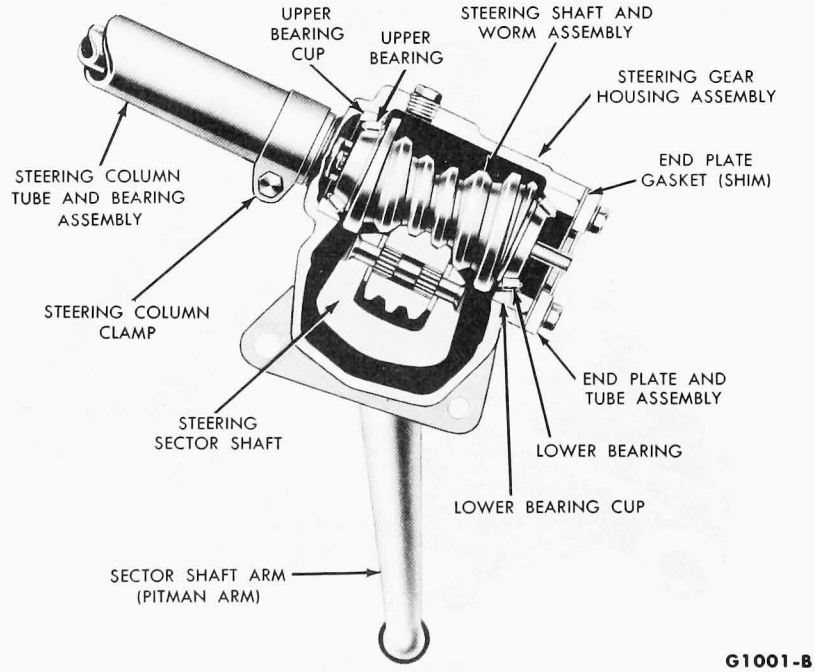

FIG. 10 Typical Gemmer Steering Gear—Sectional View

screws and remove the upper cover from the gear (Fig. 14). Care must be used to removee burrs and paint from the input shaft to avoid cutting the seal.

4. Install the upper cover attaching screws in the actuator housing with 3/8 inch thick spacers under the screw heads. This will hold the actuator and cam assembly in the gear during the adjustment.
5. Straighten the lock washer prong and remove the adjusting nut, lock washer, and the upper thrust washers and bearing.
6. Check the condition of the adjusting nut and cam shaft threads to be sure they are free from interference. This can be done by threading the nut on the shaft without the use of tools. If the nut cannot be installed all the way without tools, the threads must be repaired.
7. Position a thrust washer, thrust bearing, thrust washer, tongued washer (with internal lug) and a new lock washer on the shaft. Then, install the adjusting nut. **Do not bend the lock washer prongs at this time. The lock washer (Fig. 14) should be replaced every time the adjusting nut is moved.**
8. Torque the adjusting nut to 10 ft-lbs. Then, back the nut off 10 to 20 degrees (approximately 1 1/2 widths of the tongued washer lug). **The centering washers must be properly centered on the actuator during this adjustment.** Bend the lock washer lug that is nearest in alignment with a notch in the adjusting nut so that the lug is tight against the notch root.
9. Remove the 3/8 inch spacers and install the upper cover.
10. Position the U-joint on the steering gear input shaft and install the clamp bolt and nut.

Stud Roller Bearing Adjustment

The output shaft must be removed from the steering gear to adjust the stud roller bearing.

The operation of a properly adjusted roller bearing may feel rough when turned by hand. However, under a steering load it will be smooth and will give normal service life.

1. Wash the bearings in solvent, dry, and lubricate with gear lubricant. If a roller is lost or damaged, a new set should be installed. **Do not make partial replacement of the rollers.**
2. Assemble the bearing and install a new locking washer.
3. Install the adjusting nut and tighten as required to obtain a 1 to 4 in-lb preload on the bearing.
4. Rotate the stud several complete turns in each direction. Then check the rotational torque of the bearing and re-adjust to 1-4 in-lb if necessary.
5. Lock the adjustment with two lock washer prongs against the side of the nut. **If the lock washer is not replaced, the used prongs should be removed from the washer.**
6. Lubricate the bearing with steering gear lubricant.

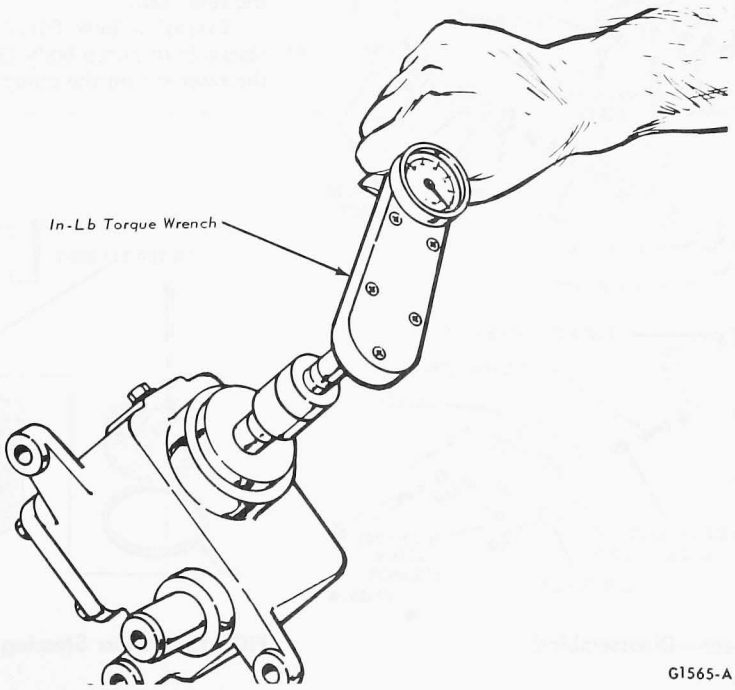

FIG. 11 Checking Steering Gear Preload—F-B-L-W-and C-500-9000

ROSS HF-54 AND HF-64 INTEGRAL STEERING GEAR

Sector Shaft Adjustment

1. Disconnect the drag link from the Pitman arm.
2. Center the steering wheel. Grasp the Pitman arm and check it for free

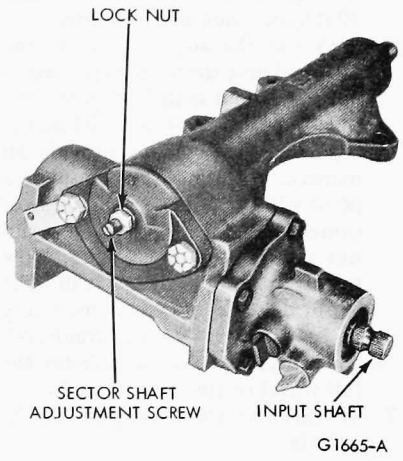

FIG. 12 Adjusting Mesh Load

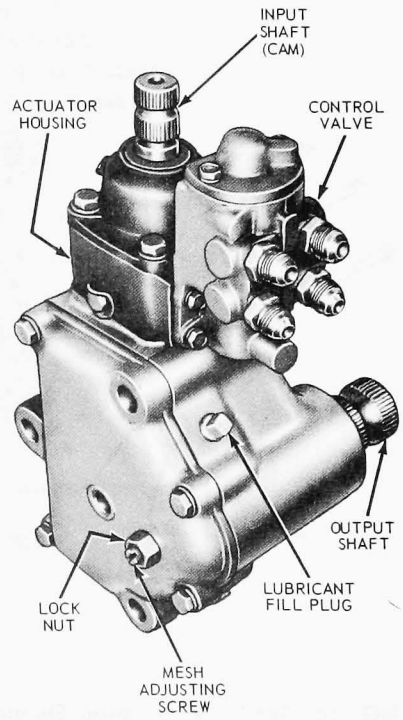

FIG. 13 Power Steering Gear

movement (lash) between the sector shaft and the rack piston.

3. If free movement is noted (lash), remove the steering gear from the vehicle. Refer to Group 13 of the 1973 Truck Shop Manual.
4. Loosen the sector shaft adjustment screw lock nut on the side cover.
5. After rotating the input shaft through its full travel for a minimum of five cycles, adjust the sector shaft adjusting screw to provide 15-20 in-lb torque as the input shaft is rotated 90 degrees each side of center.
6. Back out the adjusting screw one turn and note the torque required to move the input shaft 90 degrees each side of the center position. Move the adjusting screw in to provide an increase in torque of 2-4 in-lb at a point within 45 degrees each side of center after the adjusting screw jam nut is first tightened snug. Now torque to a final 20-25 ft-lb. The input torque of the completely assembled gear, minus hydraulic oil, should not exceed 15 in-lb for the full travel of tthe output shaft.
7. Install the steering gear in the vehicle.
8. Connect the drag link to the Pitman arm.
9. Connect the pump lines and refill the system with the specified fluid (Part 50-03).

POWER STEERING PUMP BELT TENSION ADJUSTMENT

Pump drive belt tension should not be checked using the thumb pressure or belt deflection methods. Correct belt adjustment is assured only with the use of a belt tension gauge.

1. Check the belt tension with a belt tension gauge, Tool T63L-8620-A. Refer to the Specifications section for drive belt tension specifications.
2. Loosen the pump attaching bolts, and pivot the pump to loosen or tighten the belt tension as necessary. **Do not pry on the reservoir.**
3. Torque the belt adjusting bolt to 30-35 ft-lbs. Check the tightness of the other mounting bolt (20-25 ft-lbs torque).
4. When all bolts have been properly tightened, make a final check of the pump belt tension.

REPLACE POWER STEERING PUMP RESERVOIR FLUID FILTER—EXCEPT F-100-250 BRONCO AND ECONOLINE

Remove nut and two washers securing reservoir cover and seal. Remove cotter pin, washer, spring, and retainer plate. Lift out filter element and replace with a new one. Reassemble parts securing filter element, seal and reservoir cover in reverse order of disassembly (Fig. 15). Be sure cover gasket is properly seated. Secure cover with wing nut and two washers.

TORQUE CHECKS

Tighten all attaching bolts and nuts at the intervals outlined in the Maintenance Schedules (Part 50-02) to the torque specified in the Specifications Section of this Part or the 1973 Truck Shop Manual.

POWER STEERING FILTER REPLACEMENT—EATON

Disconnect pressure line from steering pump and drain oil into a pan (1 gal. minimum). Disconnect the return line from the reservoir. On some installations it may be necessary to remove the pump from the vehicle. Remove the reservoir mounting studs and nuts (Fig. 16). Carefully rock the reservoir back and forth and remove it from the pump. **Do not pry the reservoir off the pump.** Remove the filter, filter relief spring and filter cap from inside the reservoir.

Install a new filter and a new reservoir to pump body O-ring. Install the reservoir on the pump and connect

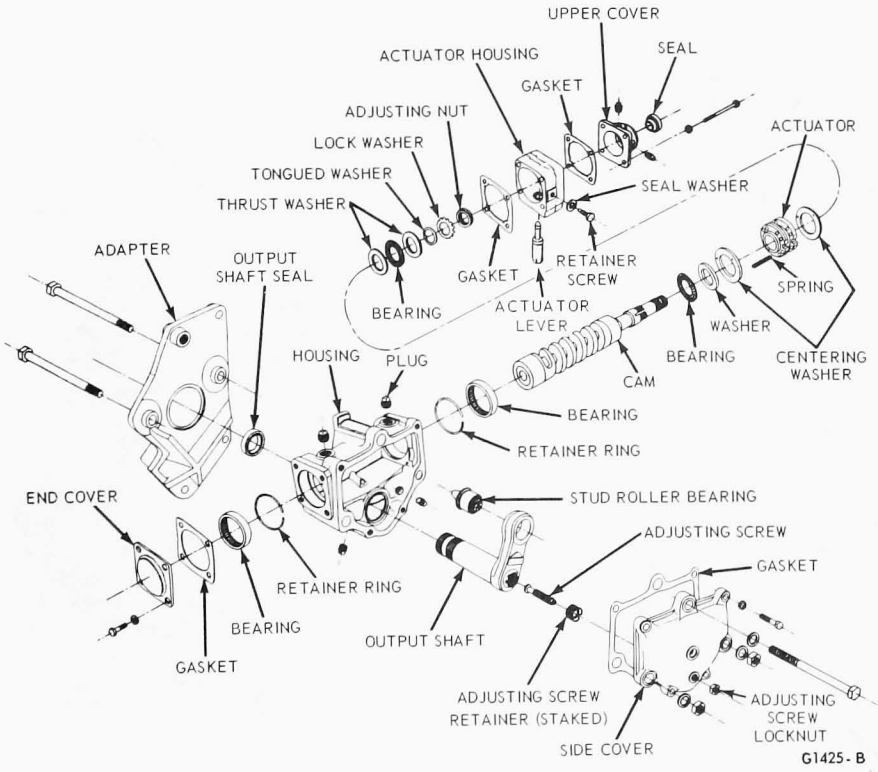

FIG. 14 Semi-Integral Power Steering Gear—Disassembled

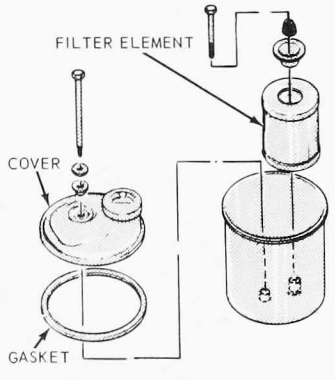

FIG. 15 Power Steering Pump Filter

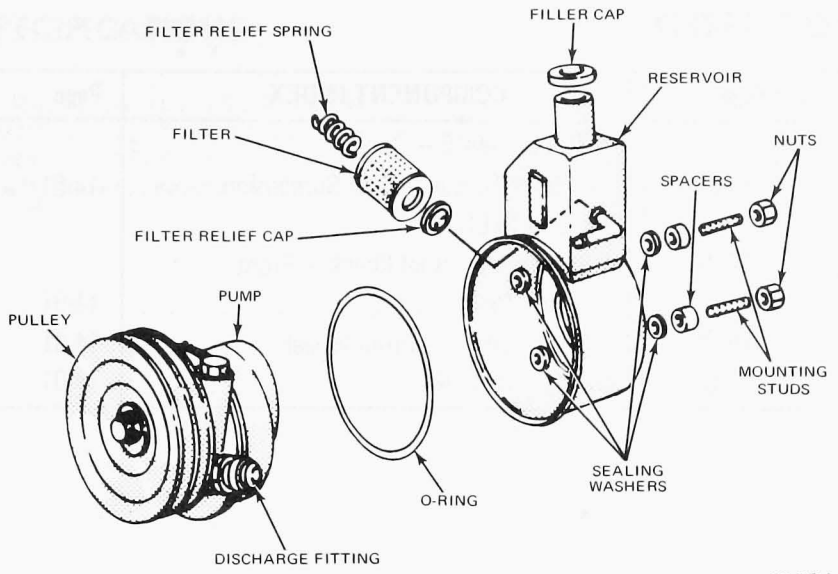

FIG. 16 Power Steering Filter Replacement—Eaton Heavy Duty

the hoses. Fill the reservoir to the cold fill mark. Run the engine for several minutes and refill reservoir to cold fill mark. Run engine and turn steering wheel from side to side several times to bleed air. Refill reservoir to cold fill mark.

SPECIFICATIONS

Refer to the 1973 Truck Shop Manual for any Specifications or Special Tools not contained in this Section.

DRIVE BELT TENSION

Belt Width	Minimum Tension (for use at maintenance interval only) (Hot Engine)	Installation Tension	
		Used Belt ①	New Belt
1/4"	30 lbs.	60 lbs.	80 lbs.
3/8" and 15/32"	50 lbs.	110 lbs.	140 lbs.
1/2"	50 lbs.	110 lbs.	140 lbs.

① Any belt that has operated for ten minutes or more is considered a used belt.

CY1523-A

PART 50-14 Suspension

COMPONENT INDEX	Page	COMPONENT INDEX	Page
LUBRICATION		MAINTENANCE – Cont.	
Spindle Pins Lubrication – Front Axle	14-01	U-Bolts Torque – Rear Suspension	14-01
Spring Leaves and Shackle Pins – Front and Rear	14-01	PRE-DELIVERY	
MAINTENANCE		Suspension Visual Check – Front and Rear	14-01
Spring Inspection	14-01	Toe-In Check – Front Wheel	14-01
Torque Checks	14-01	SPECIFICATIONS	14-01

PRE-DELIVERY

CHECK FRONT WHEEL TOE

Check the toe with the front wheels in the straight-ahead position. Measure the distance between the extreme front and also between the extreme rear of both front wheels. Both of these measurements (front and rear of wheels) should be taken at an equal distance from the floor and at the approximate center line of the spindle. The difference between these two distances is the amount that the wheels toe-in or toe-out. The wheels should always be adjusted to toe according to specifications in the Specifications Section of the Truck Shop Manual, Volume One, Part 14-01 this Part.

If the toe is incorrect, loosen the clamp bolts at each end of the spindle connecting rod tube. Rotate the tube until the correct toe is obtained, and torque the clamp bolts to specifications. Recheck the toe to make sure that no changes occurred when the bolts were tightened.

VISUALLY CHECK FRONT AND REAR SUSPENSION

Inspect the front and rear suspension for proper assembly and components. Check to assure that all lock tabs are bent for nut or bolt retention and that all cotter pins are properly installed.

LUBRICATION

LUBRICATE FRONT AND REAR SPRING LEAVES AND SHACKLE PINS

Apply the specified Chassis Lube (Part 50-03) to the shackle pin fittings with a pressure gun. Apply SAE 10W engine oil to the spring leaves with a squirt can.

LUBRICATE FRONT AXLE SPINDLE PINS (BOLTS)

Apply the specified Chassis Lube (Part 50-03) with a pressure gun at the fittings on both spindles.

MAINTENANCE

INSPECT SPRINGS AND TIGHTEN U-BOLTS

Inspect the spring leaves for being broken or sagged.

Tighten the spring U-bolts to specification as required (Specifications Section).

TORQUE CHECKS

Tighten all attaching bolts and nuts at the intervals outlined in the Maintenance Schedules (Part 50-02) to the torque specified in the Specifications Section of the 1973 Truck Shop Manual.

SPECIFICATIONS

Refer to the 1973 Truck Specifications Book Truck Shop Manual, Volume One, for the Suspension Specifications.

PRE-DELIVERY	
Axle Control Operation – 2-Speed Axle	15-01
Axle Shaft Flange Nuts Torque Check	15-01
Rear Axle Nuts Torque Check – Saddle Delivery Units	15-01
SPECIFICATIONS	15-05

PRE-DELIVERY

TORQUE REAR AXLE NUTS ON SADDLE MOUNTED UNITS

Check these nuts at pre-delivery to be sure they are tightened to the specified torque. Use a criss-cross sequence to assure even tightening.

TORQUE AXLE SHAFT FLANGE NUTS

Check the axle shaft nuts to be sure they are tightened to the specified torque. Use a criss-cross sequence to assure the nuts are tightened evenly.

SPEED AXLE CONTROL

Operate axle control switch and check for correct axle shift, engagement, and operation.

LUBRICATION

CHECK AXLE LUBRICANT LEVEL

Where magnetic drain plugs are used, the plugs should be cleaned each time they are removed.

Clean dirt and grease from the area around the filler plug, and remove the filler plug at the locations shown on the Lubrication Charts (Part 50-03). If additional lubricant is required, use only the specified type.

When checking lubricant level, the axle must be in running position (normal curb attitude). If checked on a frame contact hoist, use safety stands to hold the axle in normal curb attitude.

FORD AXLE

If the filler hole is in the housing cover, fill to the bottom of the filler hole. If the filler hole is in the carrier casting, fill to a maximum of 5/8 inch below the bottom of the filler hole.

ALL AXLES EXCEPT FORD AND TANDEM

Remove the filler hole plug. The lubricant should be level with the bottom of the hole.

TANDEM DRIVE AXLES

The axle must be run first, then allowed to stand for 5 minutes. The power divider and the forward rear axle use the same lubrication system and the 5-minute interval allows the lubricant to settle to the proper levels in the power divider case and axle housing. After the 5 minutes, check the lubricant level in the rear filler hole of the forward tandem axle only. It is not necessary to check the oil level in the power divider. If the level is up to the bottom of the filler hole of the forward rear axle, the power divider is also adequately lubricated. If the level is not up to the bottom of the filler hole, add the necessary lubricant. Check the rear tandem axle lubricant level through the rear filler hole.

DRAINING AND FILLING AXLE LUBRICANT

The ability of any axle to deliver quiet trouble-free operation over a period of years is largely dependent upon the use of good quality gear

lubricant. To insure long life for gears and bearings, use only the specified gear lubricants (Part 50-03).

DRAINING

Dana Axles and 4 x 4

Clean dirt and grease from the area around the fill plug, remove the fill plug and the cover lower bolt, and let the lubricant drain out at the bottom of the cover.

Ford Axles

Clean dirt and grease from the area around the fill plug, remove the fill plug, and draw out all the old lubricant through the fill plug hole with a suction pump.

All Axles Except Ford and Dana

To drain, unscrew the plug at the bottom of the housing and allow sufficient time for all the old lubricant to run out. On tandem drive axles, it is also necessary to unscrew the plug at the bottom of the power divider for drainage of lubricant in the power divider.

FILLING SINGLE-SPEED AXLES

Ford Axle

If the filler hole is in the housing cover, fill to the bottom of the filler hole. If the filler hole is in the carrier casting, fill to a maximum of 5/8 inch below the bottom of the filler hole.

All Except Ford Axles

Fill the axle through the filler hole until oil flows from the bottom of the hole. After filling the axle with the specified amount of lubricant, install the filler hole plug.

FILLING 2-SPEED AXLES

Fill the axle through the rear filler hole with the specified amount of lubricant (lubricant should be at the level of the bottom of the filler hole), then install the filler hole plug. If the carrier assembly oil channels are dry, one pint of lubricant should be added through the front filler hole.

Planetary Double Reduction Axles

Fill the axle through the rear filler hole with the specified amount of lubricant (lubricant should be at the level of the bottom of the filler hole), then install the filler hole plug. If the carrier assembly oil channels are dry, one pint of lubricant should be added through the front filler hole.

Tandem Drive Axles

Fill both axles with the specified amount until the lubricant is level with the bottom of the rear filler hole. Then, add the specified amount to the power divider through the filler hole located in the power divider case.

Eaton D Series Tandem Drive Axles

Fill the forward drive axle until the lubricant is level with the bottom of the filler hole in the rear cover. Then, add two pints through the forward filler hole located slightly offset to the right in the top portion of differential carrier. **Do not use the rear hole at top of the differential carrier as a lubricant filler hole. Fill the rear axle in accordance with instructions for single reduction, 2-speed or planetary double reduction, depending on the type of axle used.**

LUBRICATE UNIVERSAL JOINTS AND SLIP YOKE

1. Wipe all old lubricant and dirt from each universal joint lube fitting. Apply C1AZ-19590-B Lube to each universal joint lubrication fitting. Be careful not to force the seals out of position.

Properly lubricated joints will show lubricant seeping from all four journal cross bearing seals. If lubricant does not appear at a bearing seal, rotate the drive shaft so that the opposite bearing cap is facing downward. Exert downward pressure on the drive shaft and apply lubricant gun pressure to the fitting. Lubricate the slip yoke with C1AZ-19590-B.

2. Wipe excess lubricant from the fittings.

CHECK 2-SPEED AXLE AIR SHIFT MOTOR OIL LEVEL

The level should be maintained at the bottom of the filler plug hole. Above 0 degrees F, use SAE 10W engine oil. Below 0 degrees F, use three parts of SAE 10W engine oil to one part of kerosene. The oil and kerosene mixture can be used safely up to 32 degrees F, if necessary.

FRONT WHEEL BEARINGS—REPACK

4-WHEEL DRIVE VEHICLES

1. Raise the vehicle and install safety stands.
2. Remove the wheel cover, if installed.
3. Remove the front hub grease cap. Remove the driving hub retaining snap ring (Fig. 1) and slide the splined driving hub from between the axle shaft and the wheel hub. Remove the driving hub spacer. (If equipped with free-running lock-out hubs refer to Group 15, Truck Shop Manual).
4. With Tool T59T-1197-B, remove the lock nut, washer, and wheel bearing adjusting nut (Fig. 1) from the spindle. Remove the wheel, hub and drum as an assembly. Back off the brake adjusting screw, if necessary. The wheel outer bearing will be forced off the spindle at the same time. Protect the spindle and inner bearing cone from dirt.
5. Remove the grease retainer and the inner bearing cone and roller assembly from the hub with Tool 1175-AB and T50T-100-A.
6. Clean the lubricant off the inner and outer bearing cups with solvent and inspect the cups for scratches, pits, excessive wear, and other damage. If the cups are worn or damaged, remove them with a drift.
7. Soak a new grease retainer in light engine oil at least 30 minutes before installation. Thoroughly clean the inner and outer bearing cones and rollers with solvent, and dry them thoroughly. **Do not spin the bearings with compressed air.**

Inspect the cone and roller assemblies for wear or damage, and replace them if necessary. The cone and roller assemblies and the bearing cups should be replaced as a unit if damage to either is found.

8. Thoroughly clean the spindle and the inside of the hub with solvent to remove all old lubricant.

Cover the spindle with a clean cloth, and brush all loose dust and dirt from the brake assembly. **To prevent getting dirt on the spindle, carefully remove the cloth from the spindle.**

9. If the inner bearing cup was removed, install the cup or a new cup in the hub. **Be sure to seat the cup properly in the hub.**
10. Install the outer bearing cup in the hub with a suitable tool. **Be sure the cup is properly seated in the hub.**
11. Pack the inside of the hub with specified wheel bearing grease. Add lubricant to the hub only until the grease is flush with the inside diameter of both bearing cups.
12. All old grease should be completely cleaned from the bearings before repacking them with new grease. Pack the bearing cone and roller assemblies with wheel bearing grease. A bearing packer is desirable for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.
13. Place the inner bearing cone and roller assembly in the inner cup, and install the new grease retainer. **Be sure that the retainer is properly seated.**
14. Install the wheel, hub, and drum assembly on the wheel spindle. **Keep**

the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads. (If equipped with free-running lock-out hubs, refer to Group 15 of the 1973 Truck Shop Manual).

15. Install the wheel outer bearing cone and adjusting nut. Adjust the front wheel bearings as outlined in this Part.

REPACK AND ADJUST REAR WHEEL BEARINGS (DANA AXLE ONLY)

For F-250, F-350, P-350, P-400, E-300 and F-250 (4 x 4), the wheel bearings are packed with wheel bearing lubricant C1AZ-19590-B. Axle lubricant can also flow into the wheel hubs and bearings. On these axles, wheel bearing grease is the **primary** lubricant since the grease provides lubrication until the axle lubricant reaches the bearings during normal operation. On these axles, the wheel hub is also vented through the axle housing vent.

1. Set the parking brake and loosen the axle shaft bolts.
2. Raise the rear wheels off the floor and place the work stands under the rear axle housing so that the axle is paralled with the floor.
3. Remove the axle shaft bolts.
4. Remove the axle shaft and gaskets.
5. With the axle shaft removed, remove the gasket from the axle shaft flange studs.
6. Bend the lock washer tab away from the lock nut, and then remove the lock nut, lock washer, and the adjusting nut.
7. With the type of wheel jack shown in Fig. 2, raise the wheel to the point that all wheel weight is removed from the wheel bearings. Remove the outer bearing cone. Now pull the wheel straight off the axle.
8. With a piece of hard wood which will just clear the outer bearing cup, drive the inner bearing cone and inner seal out of the wheel hub.
9. Wash all the old grease or axle lubricant out of the wheel hub, using a suitable solvent.
10. Wash the bearing races and rollers and inspect for pitting, galling, and erratic wear patterns. Inspect the roller for end wear.
11. If the bearing cups are to be replaced, drive them out with a drift. Install the new cups with the tool shown in Fig. 3 or press them in.
12. Check for proper seating of the new bearing cups by trying to insert a 0.0015 inch feeler gauge between the cup and the wheel hub.

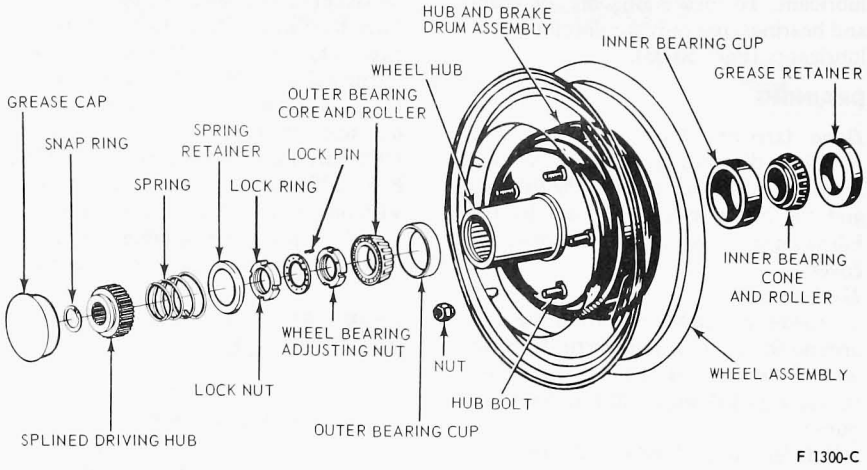

FIG. 1 Front Wheel and Hub Installation—F-Wheel Drive

13. Pack each bearing cone and roller with a bearing packer tool.
14. Place the inner bearing cone and roller assembly in the wheel hub. Install a new inner seal in the hub using tool T53T-1175-A or T53T-1175-D.
15. Adjust the jack so that the wheel can be installed straight on the axle housing without damaging the inner seal.
16. Wheel end play after assembly must be .001 to .010 inches. To obtain the specified end play, tighten the bearing adjusting nut to 50 to 80 ftlbs torque while rotating the wheel.
17. Back off (loosen) the adjusting nut 3/8 turn.
18. Apply axle lube to a new lock washer and install with smooth side out (away from adjusting nut).
19. Install lock nut and tighten to 90 to 110 ft-lbs torque using T70T-4252-P or T70T-4252-E. Wheel must rotate freely after torque.
20. With a suitable dial indicator, check wheel assembly end play (acceptable range .001 inch to .010 inch). If less than .001 inch or more than .010 inch, the procedure will have to be repeated starting with a loose bearing.
21. With a satisfactory end play and freely turning wheel, bend two lock washer tabs inward over an adjusting nut flat and two outward over the lock nut flat.
22. Install the axle shaft, gasket, lock bolts and washers. Tighten to 40-50 ft-lbs torque.
23. Adjust the brakes.
24. Use the preceeding procedure to lubricate the other wheel bearings.

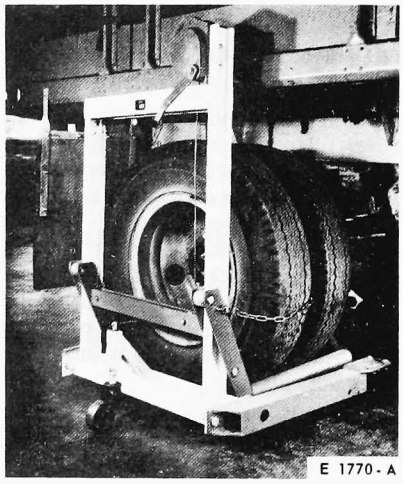

FIG. 2 Typical Wheel Jack

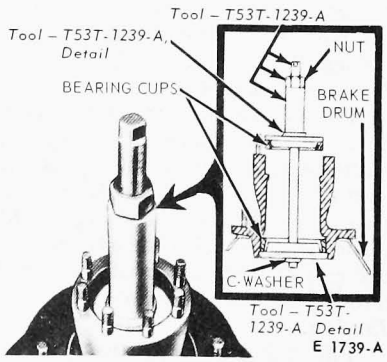

FIG. 3 Installing Wheel Bearing Cups

MAINTENANCE

CLEAN POWER DIVIDER LOCKOUT CONTROL VENT FILTER

Remove control cover, piston assembly and vent filter. Clean the parts and soak the piston felt oilers in SAE 10 oil for one hour. Clean and air dry the vent filter. Install the vent filter, piston assembly and cover on the lockout control.

2-SPEED TANDEM AXLE AIR SHIFT MOTOR VENT CLEANING

Brush off the area surrounding the vent hole to remove dirt or any other foreign matter. If the hole is plugged or partially obstructed, clear it with a piece of wire or other suitable probe.

FRONT WHEEL BEARING ADJUSTMENT—4-WHEEL DRIVE

BRONCO AND F-100

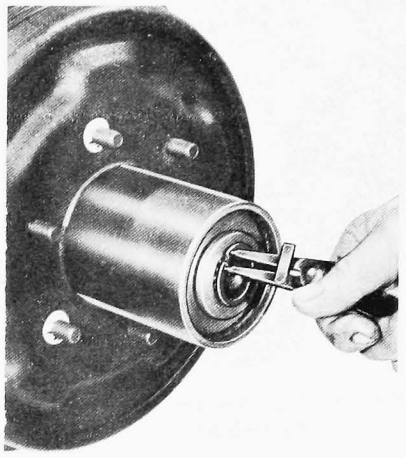
1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw if necessary.
3. Remove the front hub grease cap and the driving hub snap ring (Fig. 4).
4. Remove the splined driving hub and the pressure spring. This may require a slight prying assist (Fig. 5).
5. Remove the wheel bearing lock nut and lock ring.
6. Using Tool T59T-1197-B and a torque wrench, tighten the bearing adjusting nut to 50 ft-lbs while rotating the wheel back and forth to seat the bearings.
7. Continue rotating the wheel, loosen the adjusting nut and then retorque it to 30-40 ft-lbs.
8. Back off the adjusting nut approximately 1/4 turn (90 degrees).
9. Assemble the lock ring by turning the nut to the nearest notch where the dowel pin will enter.
10. Install the outer lock nut and torque to 50 ft-lbs. Final end play of the wheel on the spindle should be 0.001 to 0.010 inches.
11. Install the pressure spring and driving hub, the driving hub snap ring and after applying non-hardening sealer to the seating edge of the grease cap, install the grease cap. If equipped with free-running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Installation in Group 15 of the 1973 Truck Shop Manual.
12. Adjust the brake if it was backed off.
13. Remove the safety stands and lower the vehicle.

F-250

1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw, if necessary. Remove the wheel cover, if installed.
3. Remove the front hub grease cap. Remove the driving hub retaining snap ring and slide the splined driving hub from between the axle shaft and the wheel hub (Fig. 1). Remove the driving hub spacer. (If equipped with free-running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Removal in Group 15 of the 1973 Truck Shop Manual).
4. With Tool T59T-1197-B, remove the lock nut and lock ring from the spindle.
5. Using Tool T59T-1197-B and a torque wrench, tighten the bearing adjusting nut (Fig. 1) to 50 ft-lb, while rotating the wheel back and forth to seat the bearings.
6. Continue rotating the wheel and then, loosen and retorque the adjusting nut to 30-40 ft-lb.
7. Back the adjusting nut off approximately 1/4 turn (90 degrees). Assemble the lock ring by turning the nut to the nearest notch where the dowel pin will enter.
8. Install the outer lock nut and torque to 50 ft-lb. Final end play of the wheel on the spindle should be .001 to 0.010 inch.
9. Install the driving hub, spacer, snap ring and hub grease cap. Apply a thin coat of non-hardening sealer to the seating edge of the grease cap, before installation. (If equipped with free-running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Installation in Group 15 of the 1973 Truck Shop Manual).
10. Adjust the brake, if backed off to permit drum removal.
11. Remove the safety stands and lower the vehicle.

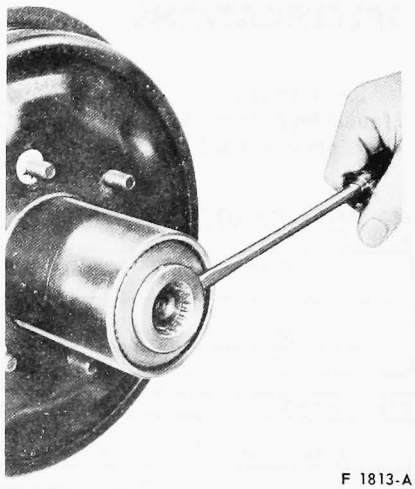
F-600

1. Remove the outer hub cap retaining screws, and remove the cap.
2. Remove the retaining lock ring (Fig. 6).
3. Remove the retaining screws and remove the splined drive plate.



F 1812-A

FIG. 4 Removing Snap Ring



F 1813-A

FIG. 5 Removing Splined Driving Hub

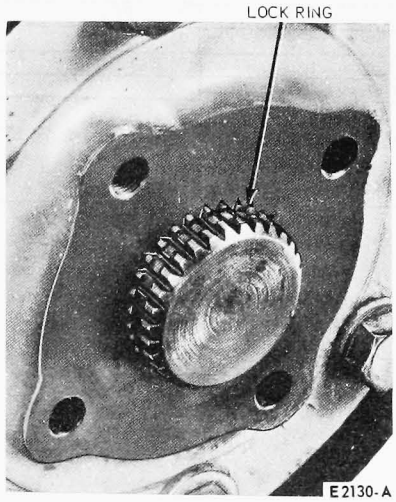


FIG. 6 Access to Lock Ring

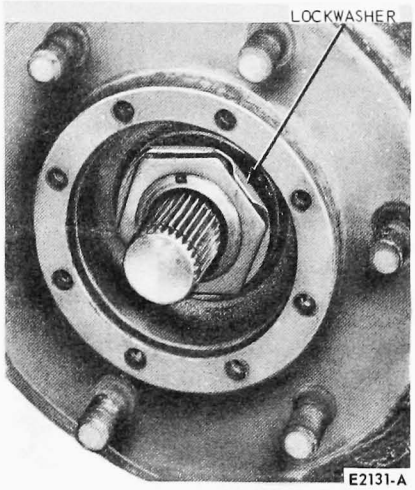

FIG. 7 Lock Nut and Washer Assembled

4. Bend the tab of the lock washer away from the lock nut and remove the lock nut (Fig. 7).
5. Remove the lock washer and **discard** it.
6. While rotating the wheel back and forth to correctly seat the bearings, torque the adjusting nut to 50 ft-lbs.
7. Back off the adjusting nut from 1/4 to 1/3 turn.
8. Position a **new** lock washer against the adjusting nut and apply a film of oil to the outer face of the lock washer.
9. Run the lock nut up against the lock washer and torque it to 100-150 ft-lbs.
10. Bend one tab of the lock washer over the adjusting nut.
11. Bend one tab of the lock washer (in the opposite direction) over the lock nut. **Use a blunt tool when bending the tabs to avoid making any chips which could cause serious bearing damage.**
12. Apply Silastic Sealer to the front and rear mounting faces of the splined drive plate.
13. Position the drive plate, install the retaining screws and torque them to specifications.
14. Install the retaining lock ring.
15. Position the outer hub cap and install the retaining screws and torque them to specifications.

SPECIFICATIONS

Refer to the 1973 or Truck Shop Manual for any Specifications or Special Tools not contained in this Section.

REAR AXLE LUBRICANT CAPACITIES

BRONCO		
Axle – Rear	Approx. Capacity (Pts.)

Shift Operation – Transfer Case	16-01
SPECIFICATIONS	16-23

PRE-DELIVERY

CLUTCH OPERATION

Check free travel and full return of the clutch pedal and disengagement of the clutch. Check for chatter, slipping, excess pedal efforts or noise. Refer to the specifications (Specifications Section) for free travel measurements. Adjust if required as outlined in Maintenance.

CHECK HYDRAULIC CLUTCH MASTER CYLINDER FLUID LEVEL

The clutch master cylinder reservoir should be filled to within 1/2 inch from the top. Use only the specified fluid (Part 50-03).

TRANSFER CASE SHIFT OPERATION

Check to be sure the transfer case shifts properly from one range to another. Check 4-wheel drive engagement and disengagement.

TRANSMISSION SHIFT LEVER

Check the transmission for smooth shifting operation through all gears. Adjust the transmission shift linkage if necessary. Refer to Group 16 of the 1973 Truck Shop Manual for the adjustment procedure.

CHECK TRANSMISSION LUBRICANT LEVEL

Refer to the lubrication section of this Part for the lubricant level checking procedure.

LUBRICATION

LUBRICATE CLUTCH LINKAGE PIVOTS AND CLEVISES

Lubricate all clevis pins and pivot points sparingly with SAE 10W engine oil.

LUBRICATE CLUTCH EQUALIZER

Wipe the lubrication fitting clean on the clutch equalizer (where so equipped), and apply Chassis Lube as specified in the lubricants chart (Part 50-03).

LUBRICATE CLUTCH PEDAL PIVOT SHAFT

On all except P-Series, apply SAE 10W oil to the clutch shaft. On P-Series, apply the specified Chassis Lube (Part 50-03), with a pressure gun at the fitting.

LUBRICATE CLUTCH RELEASE BEARING

Apply lubricant to the pressure grease fitting on the bearing hub (all medium duty vehicles equipped with super duty or Diesel engines). **Do not use ordinary chassis lubricant. Do not over-lubricate.** Use only high temperature lubricant meeting Ford Specifications (Part 50-03).

LUBRICATE TRANSMISSION LINKAGE PIVOTS

Lubricate all clevis pins and pivot points with SAE 10W engine oil. Wipe the lubrication fitting on the first and reverse shift lever at the lower end of steering column and apply Specified Chassis Lube (above 10 degrees F) or calcium soap grease (below 10 degrees F). Refer to the Lubricant Specifications in Part 50-03.

LUBRICATE SPICER 16-SPEED TRANSMISSION CONTROL VALVE BODY, SPLITTER AND RANGE CONTROLS

CONTROL VALVE BODY

1. Wash off the top of the control valve body to expose the 1/8 inch pipe plug located in the center of the valve body.
2. Place the gear shift lever in one of the manual-shift positions to shut off the air to the valve body.
3. Remove the pipe plug, using caution to prevent dirt entering the opening.
4. Have an assistant operate both splitter and range control handles while applying approximately one tablespoon of castor oil through the pipe plug opening.
5. When valve body is full, replace the pipe plug.

SPLITTER CONTROL

Apply engine oil through the lubricating hole provided in the splitter control lever. Rotate splitter to work oil film over the inner sleeve.

RANGE CONTROL

Pull the range control handle into the up position. Wipe off old oil film, dirt, etc. When clean, apply a light film of oil to the plunger and operate the handle up and down to distribute lubricant.

LUBRICATE TRANSMISSION REMOTE GEAR SHIFT AND AUXILIARY TRANSMISSION LINKAGE, CABLES AND U-JOINTS

For prevailing temperatures above 10 degrees F, apply the specified chassis lubricant (Part 50-03), with a pressure gun to transmission remote gear shift front cross-shaft and levers, auxiliary transmission linkage, and transmission cables, U-joints, crank arm and side bushings (C-and W-Series only).

For prevailing temperatures below 10 degrees F, use calcium soap grease (conforming to Ford Specification in Part 50-03).

LUBRICATE FULLER TRANSMISSION AIR CYLINDER SHIFT LEVER AND LINKAGE

Apply specified chassis lubricant (Part 50-03) to linkage connections with pressure gun.

MANUAL TRANSMISSION LUBRICANT FILL PROCEDURE

3-SPEED FORD AND 4-SPEED WARNER AND NEW PROCESS TRANSMISSIONS

The following instructions should be used when a transmission has been drained for any reason: Remove the speedometer cable and fill the transmission with the specified lubricant (Part 50-03) through the speedometer cable hole in the transmission extension housing.

MANUAL TRANSMISSION LUBRICANT LEVEL AND CLEAN BREATHER (MAIN AND AUXILIARY)

1. Remove the fill plug from the side of the case.
2. If lubricant does not flow from the fill hole, fill the case with the specified lubricant (Part 50-03) until

it is level with the bottom of the fill hole.
3. Install the filler plug.
4. Clean all dirt from the breather.

DRAIN AND REFILL STANDARD TRANSMISSION—100 THRU 350 SERIES (EXCEPT 3-SPEED LIGHT AND MEDIUM DUTY FORD DESIGN)

1. Remove the filler plug from the side of the case and the drain plug from the bottom of the case. Allow the lubricant to drain.
2. Install the drain plug after the case is completely drained.
3. Fill the case with the specified lubricant (Part 50-03) until the fluid is level with the lower edge of the filler hole.
4. Install the filler plug.

CHANGE LUBRICANT IN MANUAL SHIFT OR AUXILIARY TRANSMISSIONS—500 THRU 9000 SERIES

1. Remove the filler plug and drain plug, and then let the old lubricant run out. Thoroughly flush the case with clean flushing oil or kerosene.
2. Install the drain plug.
3. Refill the case until the new lubricant is level with the bottom of the filler plug hole, and then install the filler plug.

DRAIN, FLUSH AND REFILL SPICER 16-SPEED TRANSMISSION

1. Thoroughly clean the area around the drain and filler plugs.
2. Remove the drain plug with the attached pump screen.
3. Drain the lubricant while the oil is still hot, to ensure maximum drainage.
4. Replace the drain plug.
5. Fill the transmission with 3 1/2 to 4 gallons of diesel fuel.
6. Run the engine at 800-900 rpm to 6 to 7 minutes with the transmission shift lever in 4th gear position and the auxiliary shift lever in neutral.
7. Drain flushing oil, clean the pump screen and replace the drain plug.
8. Refill the transmission with specified lubricant (Part 50-03).

DRAIN 16-SPEED SPICER TRANSMISSION AND CLEAN OIL SCREEN

1. Thoroughly clean the area around the drain and filler plugs.
2. Remove the drain plug with the attached pump screen.
3. Drain the lubricant while the oil is still hot, to insure maximum drainage.
4. Clean and replace the pump screen and drain plug and refill the transmission.

DRAIN, FLUSH AND REFILL 5-, 10-AND 15-SPEED FULLER TRANSMISSIONS

1. When the transmission is warm, remove the drain plug at the bottom of the case and drain the oil.
2. Clean the drain plug and replace it.
3. Remove all dirt from the area of the filler plug opening on the left side of the case, and remove the filler plug.
4. Fill the transmission with a clean flushing oil or kerosene to the level of the filler plug opening. Install the filler plug. **On off-highway equipment, remove the lubricating pump before flushing.**
5. With the transmission in neutral, run the engine at fast idle for a period of 10 seconds.
6. Remove the drain plug, drain the flushing oil, and replace the plug.
7. Remove the filler plug, fill the transmission with engine oil SAE 50 above 10 degrees F or SAE 30 below 10 degrees F to the level of the filler opening, and replace the plug. **Do not overfill. Overfilling will cause oil to be forced out of the case through the mainshaft openings.**

CHECK TRANSFER CASE FLUID LEVEL (4-WHEEL DRIVE)

1. Remove the fill plug from the case.
2. If lubricant does not flow from the fill hole, fill the case with the specified lubricant (Part 50-03) until it is level with the bottom of the fill hole.
3. Install the fill plug.

DRAIN AND REFILL TRANSFER CASE (4-WHEEL DRIVE)

1. Remove the filler plug from the side of the case.
2. Remove the drain plug from the bottom of the case, and allow the old lubricant to drain out.
3. Clean and install the drain plug after the case is completely drained.
4. Fill the case with engine oil SAE 50 above 10 degrees F or SAE 30 below 10 degrees F until it is level with the lower edge of the filler hole.
5. Install the drain plug.

MAINTENANCE

REPLACE SPICER 16-SPEED TRANSMISSION AIR FILTER ELEMENT

1. Remove the drain plug from the air filter (attached to the right rear side of the transmission cover).
2. After air has been exhausted from the system, remove the outer can and filter element by backing off the lock screw at the top.
3. Wash the outer can thoroughly and reassemble, using a new filter element and new gaskets for the top and bottom of the outer cam.
4. Replace the drain plug.
5. Build up air pressure in the system and check for leaks.

REPLACE OIL FILTER ELEMENT—SPICER TRANSMISSIONS IF SO EQUIPPED

1. After draining the transmission case, remove the attaching bolts and filter cover from either one or both power take-off openings in the case.
2. Remove and discard the filter element(s).
3. After the case has been thoroughly flushed out, install the new filter element(s) to the power take-off opening(s) in the case.
4. Assemble the cover(s) to the case with the attaching bolts.

CHECK FULLER TRANSMISSION AIR FILTER

Check the air filter to be sure it is properly installed and the air inlet is not restricted.

If the shifts between high and low range are sluggish, even though the

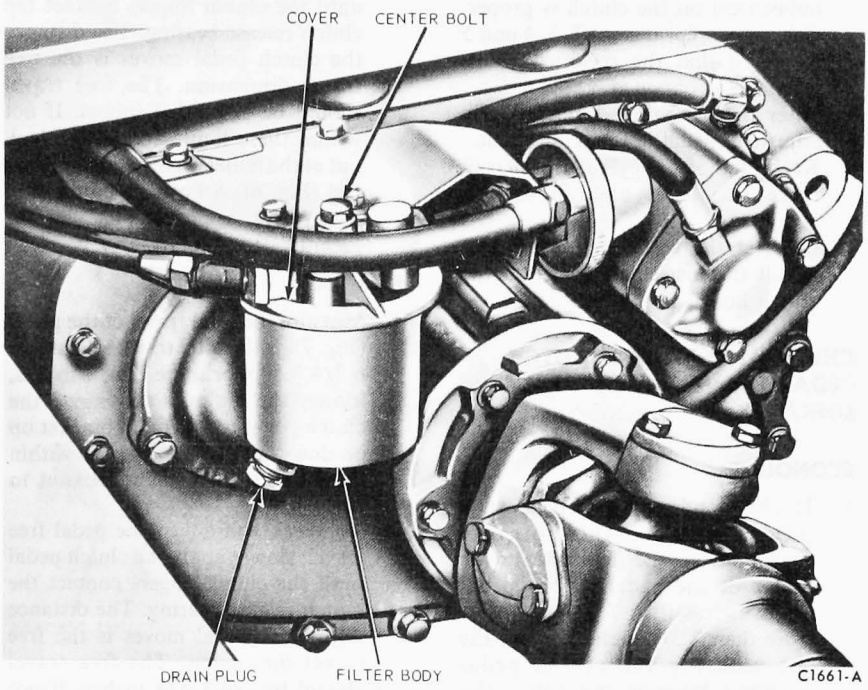

FIG. 1 Transmission Air Filter

transmission air filter is drained of water, the filter should be removed and cleaned.

1. Loosen the center bolt and remove the filter body from its cover (Fig. 1).
2. Remove the filter element from the body and clean both element and body of all dirt and/or obstruction.
3. Install the element in the body, assemble the body to its cover, and secure with the center attaching bolt.

DRAIN WATER FROM FULLER TRANSMISSION AIR FILTER

If the shifts between high and low range are sluggish, drain the water from the transmission air filter by removing the drain plug (Fig. 1).

REPLACE AIR FILTER ELEMENT—FULLER TRANSMISSION

1. Loosen the center bolt and remove the filter body from its cover (Fig. 1).
2. Remove the filter element from the body, and discard the element.
3. Clean the filter body, and install a new filter element in the body.
4. Assemble the filter body to its cover, and secure with the center attaching bolts.

INTERNAL ADJUSTMENT—MULTIPLE DISC TYPE CLUTCH

The linkage on a 14 or 15 1/2 inch multiple disc clutch should not be adjusted to compensate for clutch facing wear. Linkage should only be reset to provide proper free-pedal after the internal clutch adjustment has been made. Proper linkage settings are given at the end of this Part.

1. **To make an internal clutch adjustment, remove the inspection cover from the bottom of the clutch housing.**
2. Disconnect the retracting spring. Holding the release lever against the release bearing, measure the distance between the release bearing and the clutch spring hub on models with a synchronized transmission. On models with non-synchronized transmissions, measure the distance between the release bearing and the clutch brake. On vehicles equipped with a 14 inch or 15 1/2 inch two plate clutch, the dimension between the release bearing and the clutch spring hub should be 9/16-5/8 inch. The dimension between the release bearing and the clutch brake should be 1/2 inch (Fig. 2). On vehicles equipped with a 14 inch single plate clutch, the dimension between the release bearing and the clutch spring hub should be 11/32-13/32 inch.

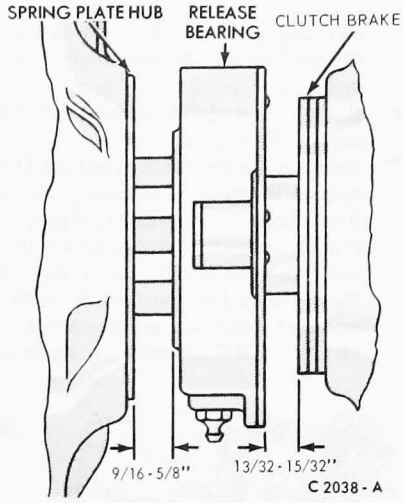

FIG. 2 Adjustment Dimensions—14 Inch Double-Disc Clutch

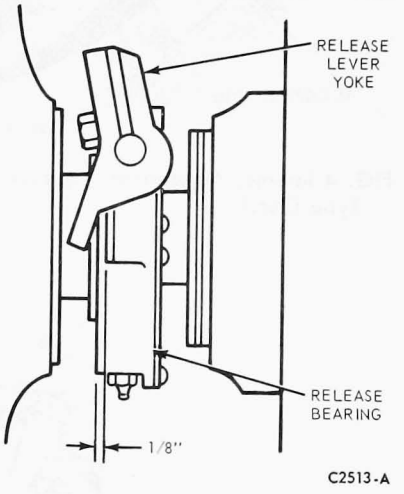

FIG. 3 Adjustment—Spicer-Type Clutch

On all Spicer type clutches, also adjust the adjusting ring to provide a 1/8 inch clearance between the release yoke fingers and the release bearing (Fig. 3).

3. Adjust the clutch assembly by rotating the engine flywheel until the adjusting ring lock and bolt are exposed. Remove the bolt and lock (Fig. 4).
4. Hold or block the clutch pedal in the released position.
5. Use a pry bar to turn the adjusting ring (Fig. 4) counterclockwise (looking from rear of vehicle) to move the release bearing toward the flywheel; or clockwise to move the release bearing away from the flywheel. Rotation or movement of

one lug position will move the release bearing approximately 1/32 inch.

6. Remove the clutch pedal block to engage the clutch.
7. Recheck the clearance as outlined in step 2. Readjust if necessary. As a final check for adequate and proper clutch adjustment, measure the distance between the centerline of the pedal pad to the firewall in the engaged position. If the distance checks 3 1/4-3 1/2 inch, the internal adjustment on the clutch is proper. Otherwise, repeat steps 2, 3, 4 and 5 above so that the specified above tolerance is obtained.
8. After the clutch has been properly adjusted, install the lock and bolt.
9. Recheck the slave cylinder push rod-to-release lever clearance if so equipped.
10. Connect the retracting spring and install the inspection cover on the clutch housing.

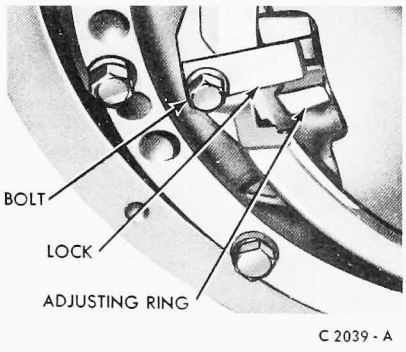

FIG. 4 Internal Adjustment—Spicer-Type Clutch

CHECK AND ADJUST CLUTCH PEDAL TRAVEL—MECHANICAL LINKAGE

ECONOLINE

1. To check and adjust the pedal total travel, measure and note the distance from the floor pan to the center of the pedal. If the pedal height is less than 7 1/2 inches or more than 7 3/4 inches, loosen the nut securing the clutch pedal eccentric bumper and rotate the bumper until the travel is within specifications (Fig. 5) Torque the locknut to 10-17 ft-lbs.
2. To check and adjust the pedal free travel, slowly apply the clutch pedal until the clutch fingers contact the clutch release bearing. The distance the clutch pedal moves is the free travel dimension. The free travel should be 3/4-1 1/2 inches. If not within these limits, loosen the lock nut at the bullet on the clutch release rod (Fig. 6). Adjust the bullet until free travel is correct. Tighten the locknut.

BRONCO

1. Measure the total travel of the pedal (Fig. 7). If the total travel is less than 6 3/4 inches or more than 7 inches, loosen the locknut and move the clutch pedal bumper and bracket up or down until the travel is within these limits. Torque the locknut to 10-17 ft-lbs.
2. To check and adjust the pedal free travel, slowly apply the clutch pedal until the clutch fingers contact the clutch release bearing. The distance the clutch pedal moves is the free travel dimension. The free travel should be 3/4-1 5/8 inches. If not within these limits, disconnect the retracting spring and loosen the nut at the bullet on the clutch release rod. Adjust the bullet until free travel is correct.

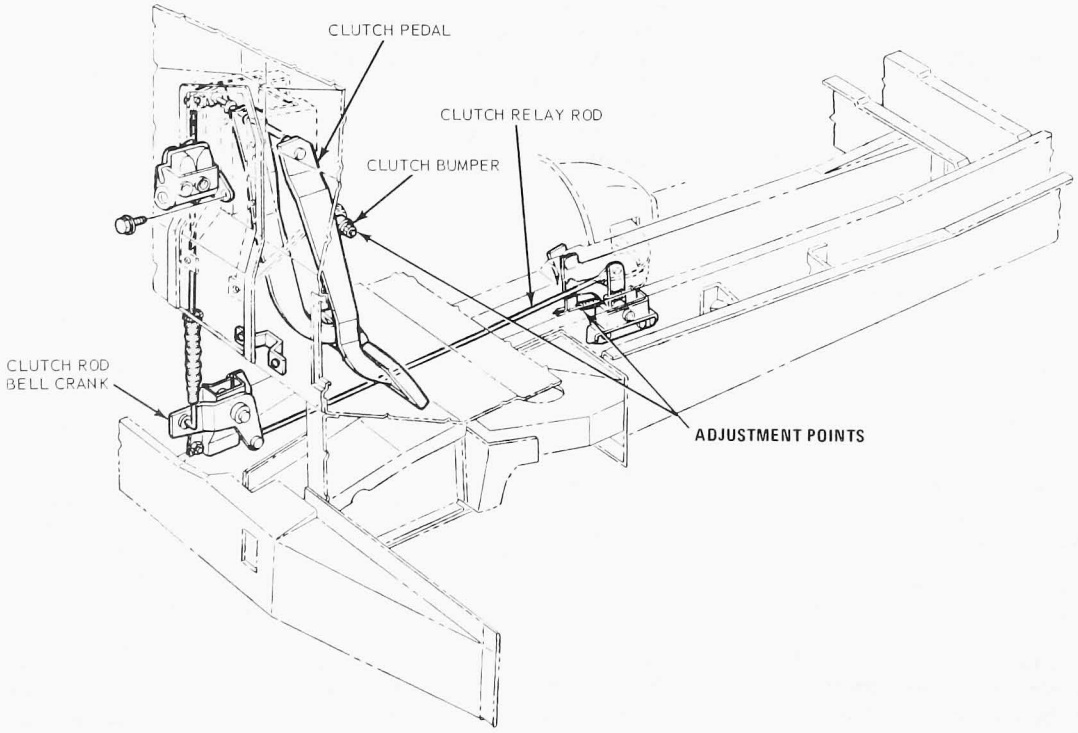

FIG. 5 Clutch Mounting and Linkage—Econoline

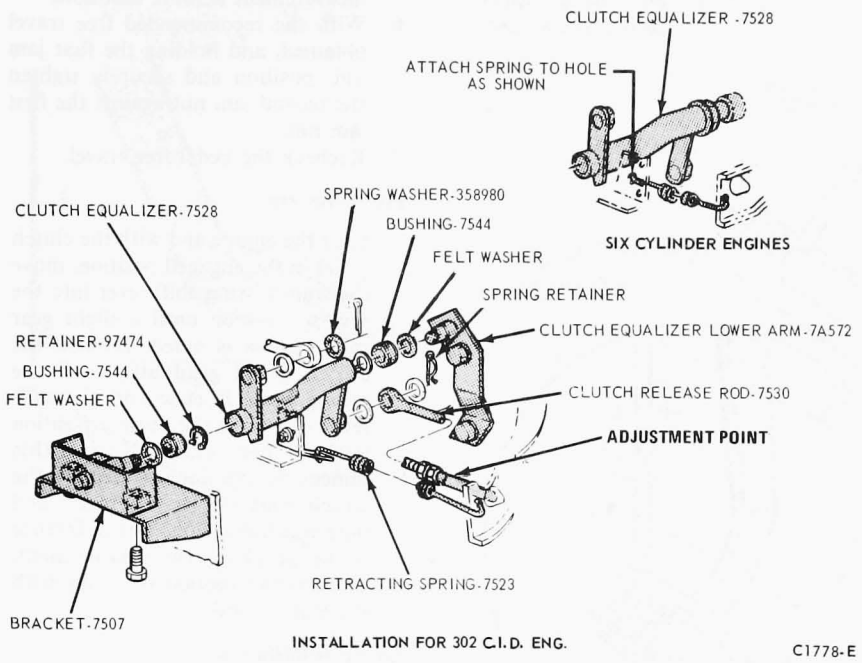

FIG. 6 Clutch Equalizer Shaft—Econoline

F-100-350 SERIES

1. Clutch pedal height is fixed in this Series and is not adjustable.
2. Measure the clutch pedal free travel using a steel tape as shown in Fig. 8. Measure the distance from the clutch pedal pad to the steering wheel rim. Depress the pedal slowly until the free travel between the release bearing assembly and the pressure plate assembly is taken up. Note this measurement. The difference between the two measurements is the free travel.
3. If the free travel measurement is less than 3/4 inches, the clutch linkage must be adjusted.
4. Loosen the two jam nuts on the release rod assembly (Figs. 9, 10 and 11) and back off both nuts several turns.
5. Loosen or tighten the first jam nut against the release rod extension (bullet) until a free-travel measurement indicates a 3/4 to 1 1/2 inch movement. A free travel measurement close to the 1 1/2 inch

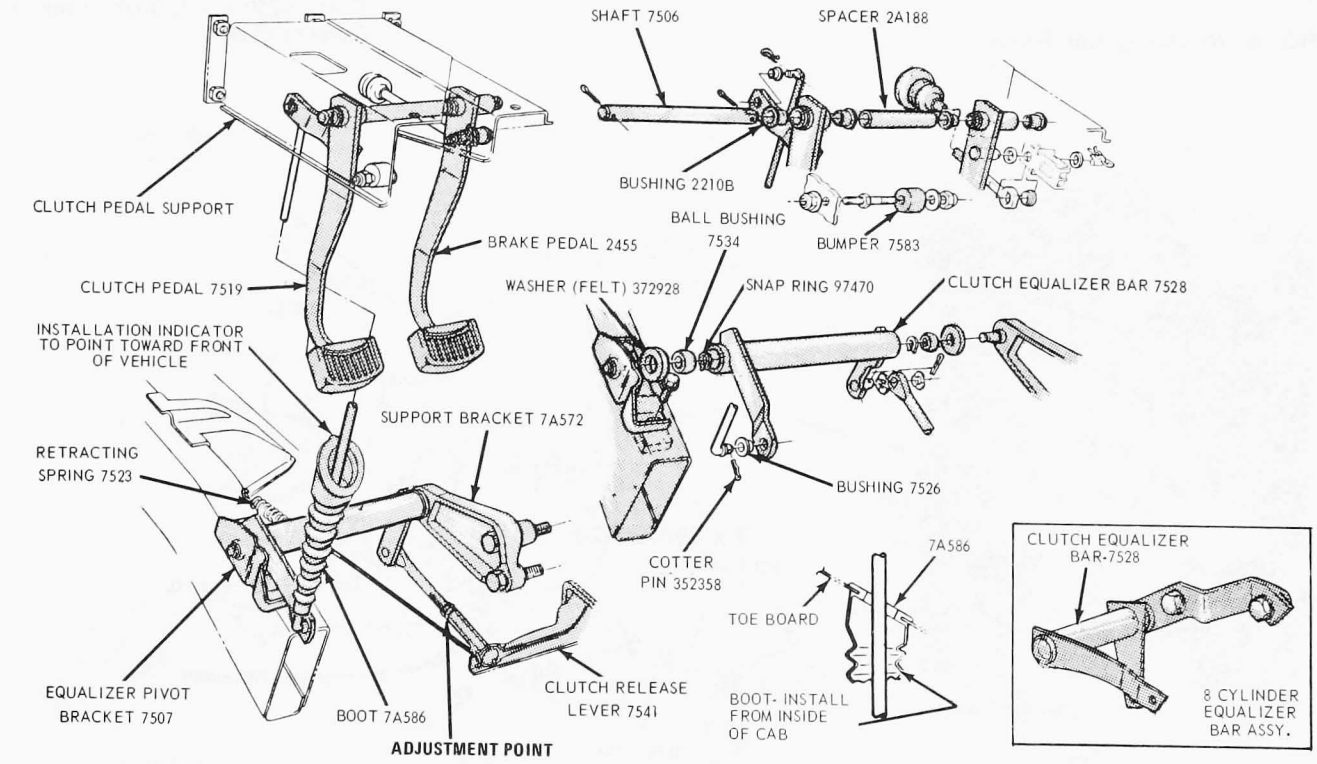

FIG. 7 Clutch Linkage—Bronco

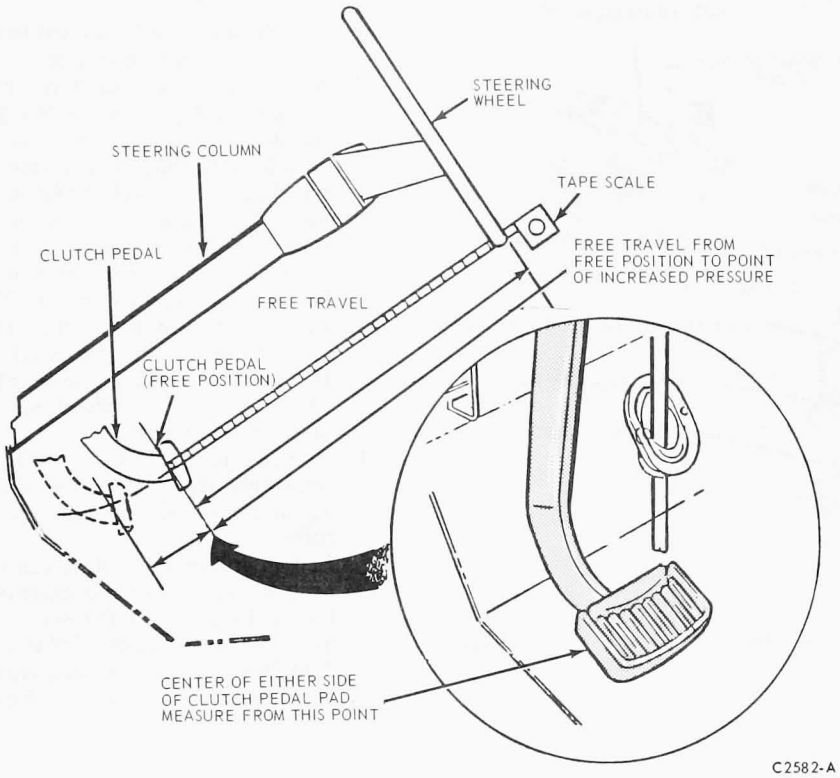

FIG. 8 Measuring Free Travel

measurement is more desirable.

6. With the recommended free travel obtained, and holding the first jam nut, position and securely tighten the second jam nut against the first jam nut.
7. Recheck the pedal free travel.

Pedal Reserve

1. Start the engine and with the clutch pedal in the engaged position, move the transmission shift lever into the reverse position until a slight gear raking noise is noted. Depress the clutch pedal gradually until the raking noise is gone and the shift lever slips into the reverse position without gear clash. Noting this dimension, continue to depress the clutch pedal to its full travel and note this dimension. The difference is the pedal reserve measurement. This reserve motion will vary with the engine used.

Spring Installation

1. Hook the short (reverse hook) end of the spring to the upper hole in the frame crossmember. Hook the long end hook into the release lever. On F-100-F-250 4 x 4, hook spring to frame bracket.

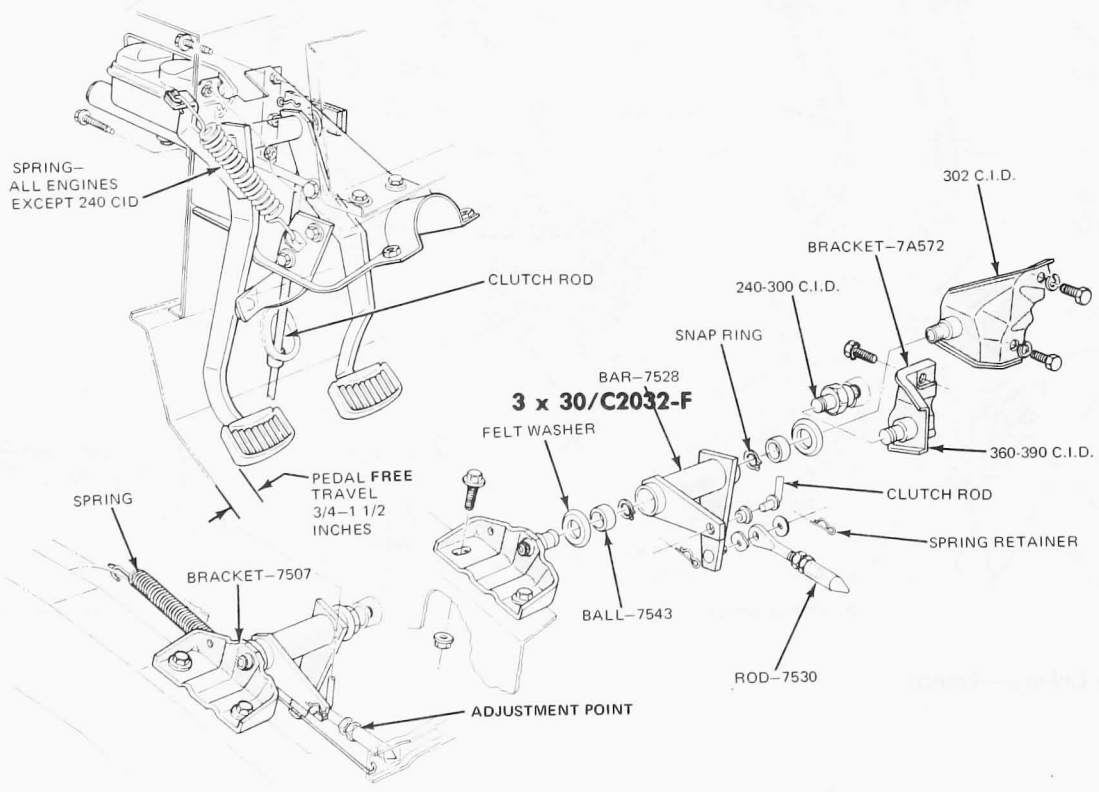

FIG. 9 F-100-350 Series Clutch

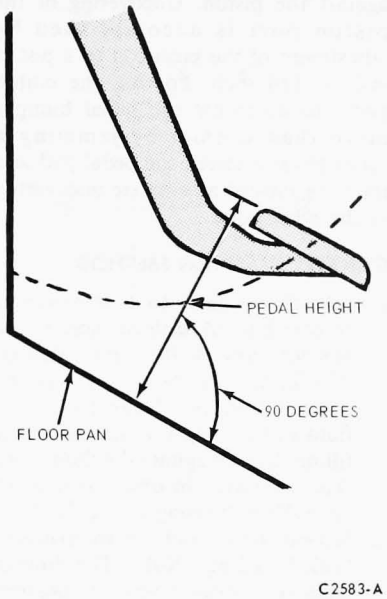

FIG. 10 Measuring Pedal Height

F-AND B-500 THROUGH 750 AND F-AND B-6000-7000

1. Adjust the clutch pedal stop to set total pedal travel within specification (Figs. 12 and 13). Torque the stop nut to specification.
2. On gas engine models, adjust the clutch pedal free travel to specification by backing off the jam nut and adjusting the spherical nut on the release push rod (Fig. 13). There should be 1/4 inch clearance between the spherical nut and the release lever. Make this adjustment with the retracting spring in place.
3. Tighten the jam nut.
4. On diesel engine models, adjust the clearance between the sleeve and lever as shown in Fig. 13. Clearance should be 1/8 inch.
5. Tighten the jam nut.

L-SERIES

A common pedal is used on all L-Series trucks (Fig. 14). Refer to Fig. 14 for instructions on adjusting pedal total travel and dimension locations for installation and free pedal measurements.

Refer to the appropriate illustrations (Figs. 15 through 21), for linkage and clutch free pedal adjustments. Note that it is not necessary to set the total clutch linkage each time the clutch is adjusted for pedal free travel. Also note that double disc Spicer type clutches are adjusted **internally** for pedal free travel. **This procedure must be used on these clutches to prevent premature clutch failure.**

W-SERIES

1. Adjust the clutch pedal stop to permit total pedal travel of 10 15/32 to 10 31/32 inches (Fig. 22). Torque the bracket attaching bolts to specifications.
2. Adjust the clutch pedal over-center assist spring by means of the spherical locking nut to provide a spring length of 7 3/16-7 5/16 inches for 500 pound clutch and 6 15/16-7 1/16 inches for 420 pound clutch. This distance should be measured inside of the spring eye ends (Fig. 23). When making the spring adjustment, hold the spring retainer from rotating and make certain the assist spring and anchor re aligned at right angles as shown in Fig. 22. When adjusting the assist

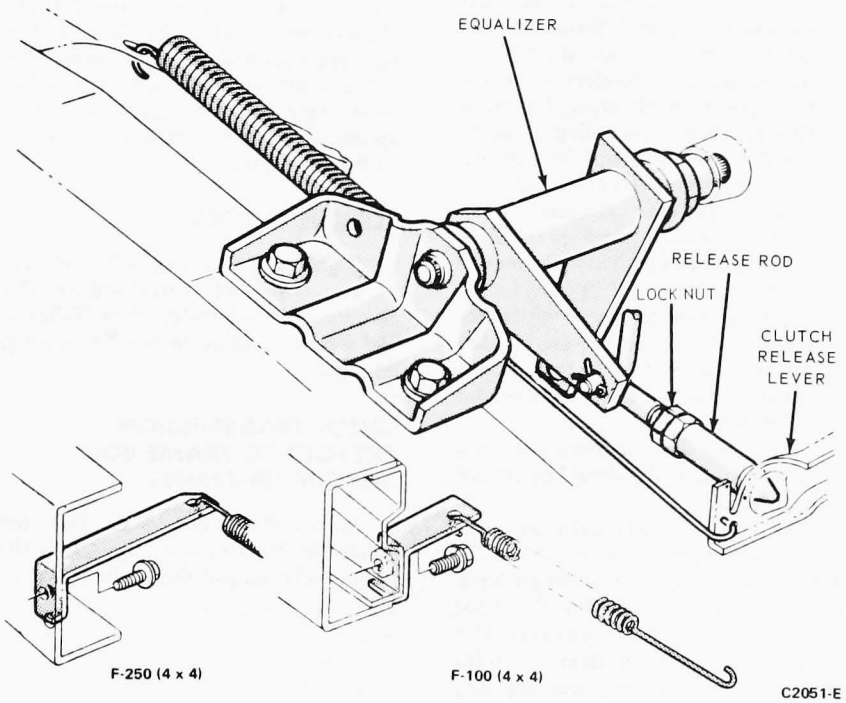

FIG. 11 Clutch Pedal Free Travel Adjustments—F-100-350 Series

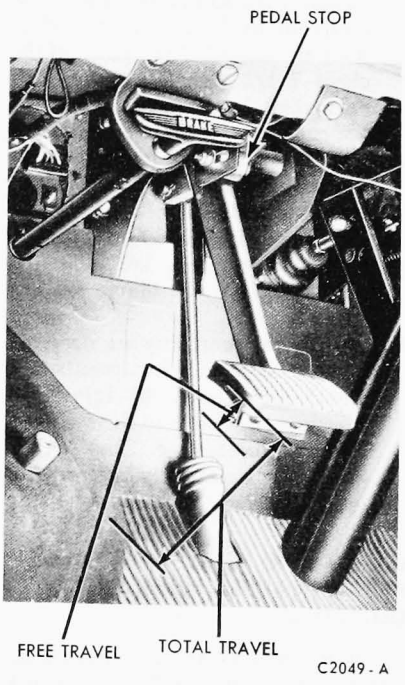

FIG. 12 Clutch Pedal Travel

spring anchor, use a deep socket wrench to avoid damaging the plastic-insert lock nut.

3. Adjust the vertical tension rod turnbuckle so that the lever (Fig. 22) is perpendicular to the top of the frame. This adjustment is to be made with the cab in the locked position and a 1/4 inch diameter aligning pin installed in the lever. After the adjustment, position the thin section of the turnbuckle toward the body sheet metal so as to provide maximum clearance between the sheet metal and radiator side support. Do not remove the aligning pin at this time.
4. With another 1/4 inch diameter aligning pin inserted through the frame bracket and outer equalizer lever, check the inner equalizer lever to be sure it is perpendicular to the top of the frame. If the lever is not perpendicular, adjust the rod length as required. Remove both aligning pins.
5. Position the linkage return spring clip to the dimension shown in Fig. 22.
6. Disconnect the equalizer rod at the clutch housing cross-shaft lever.
7. While holding the clutch housing cross-shaft lever in the rearward position, adjust the length of the equalizer rod so that the hole in the clevis and the hole in the cross-shaft lever are aligned. Then, back off the clevis 7 1/2 turns and rotate the cross-shaft lever forward. Connect the equalizer rod at the cross-shaft lever and tighten the lock nuts at all the clevis connections. The resulting clutch pedal free travel will be approximately 1 3/8-1 1/2 inches, corresponding to a 1/2 inch free bearing lash at the clutch bearing hub.
8. With linkage correctly set, make all further service adjustments for clutch facing wear by internally adjusting the clutch to the specified 1/2 inch clearance. This action should automatically restore the specified pedal free travel.

CHECK AND ADJUST CLUTCH PEDAL TRAVEL—HYDRAULIC CLUTCH

Before making any adjustments, be sure that the system is free of air and that the master cylinder fluid is at the specified level.

P-350-400

Adjust the clutch slave cylinder push rod per the instructions shown in Fig. 24.

P-500

Adjust the clutch master cylinder and slave cylinder push rods per the instructions shown in Fig. 25.

C-SERIES

Adjust the C-Series clutch pedal and clutch slave cylinder per the instructions shown in Fig. 26.

CLUTCH HYDRAULIC SYSTEM BLEEDING METHOD—ALL VEHICLES

An effective and simplified method has been developed for bleeding clutch hydraulic systems with a minimum waste of hydraulic clutch fluid. Instructions are given below:

PRESSURE TANK BLEEDING

1. Connect a transparent bleeder hose to the pressure tank hose connector. Attach the bleeder hose to the slave cylinder bleeder screw and fill the empty cylinders.
2. Adjust the pressure tank fluid flow so that the master cylinder does not fill too fast. The C-Series cylinder can be filled faster than the P-Series model master cylinders since the relief port is much larger. Too fast a flow rate will cause spillage, because a stream of fluid will be expelled from the small relief port of conventional type cylinders.
3. Close the bleeder screw on the slave cylinder when the fluid in the master cylinder reservoir is approximately 1/2 inch from the top. No further bleeding should be necessary, since all the air in the system would exhaust through the master cylinder relief port.
4. Check the slave cylinder push rod total travel, which should be at least 1 1/8 inch.

The clutch master cylinder relief port must be open in order to bleed the system. Clutch master cylinder push rod lash of 1/4 inch is required on the P-500 series vehicles to permit the conventional type master cylinder piston to return to the piston stop ring and open the relief port. The clutch master cylinder cannot be adjusted on the P-350 and 400 series vehicles. In C-Series master cylinders, the O-ring seal on the end of the push rod must not seat against the piston. Uncovering of the piston port is accomplished by adjustment of the push rod to a piston lash of 1/4 inch. Forcing the clutch pedal to compress the pedal bumper more than normal by jamming a screwdriver between the pedal pad and the floor insures a complete uncovering of the relief port.

GRAVITY BLEEDING METHOD

1. Attach a funnel to a transparent bleeder hose. Attach the hose to the bleeder screw of the slave cylinder. The funnel must be higher than the master cylinder. Pour hydraulic fluid in the funnel as the system is filling. Do not agitate the fluid more than necessary in order to prevent air bubbles forming in the fluid.
2. Repeat steps 3 and 4 as for pressure tank bleeding. **Note: The funnel method requires caution to prevent air entering the fluid as the system is being filled.**

CHECK TRANSMISSION AND AUXILIARY TRANSMISSION MOUNTINGS

Occasionally, the transmission and auxiliary transmission mountings should be visually checked. If the vehicle is operated on rough terrain, this check should be made frequently. If the mounting bolts are loose, torque them to specifications. If the insulators are worn or frayed, replace them.

TORQUE CHECKS

Tighten all attaching bolts and nuts at the intervals outlined in the Maintenance Schedules (Part 50-02) to the torque specified in the Truck Shop Manual.

CHECK TRANSMISSION SUPPORT-TO-FRAME BOLT TORQUE (W-SERIES)

Check the torque of the bolt that holds the transmission support to the frame. The torque should be 50-62 ft-lbs.

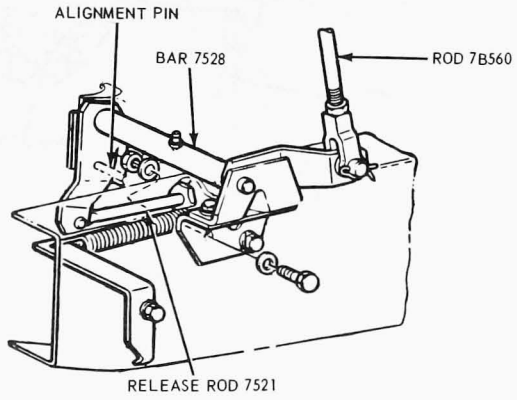
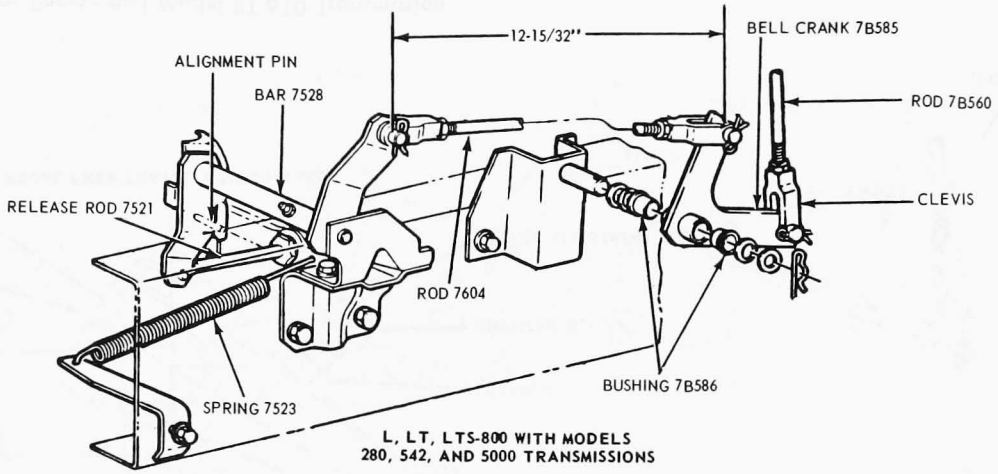
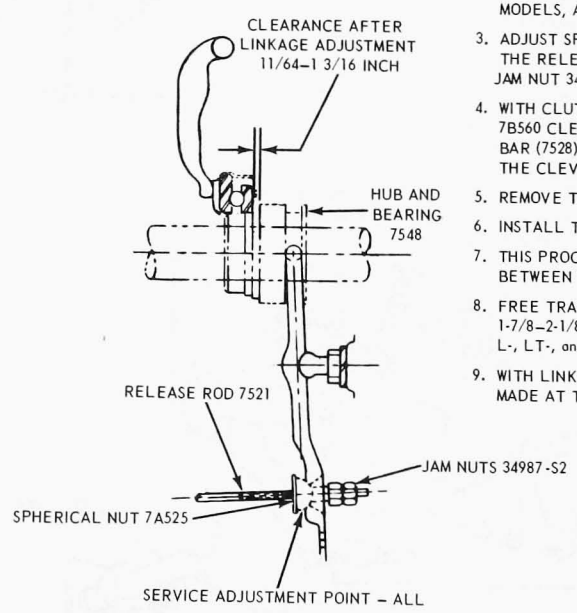
LN-, LNT-800 WITH MODELS 280, 542, OR 5000 TRANSMISSIONS



LN-600-750 WITH MODELS 280, 542, T-19, 435 AND 5000 TRANSMISSIONS



L, LT, LTS-800 WITH MODELS 280, 542, AND 5000 TRANSMISSIONS



1. ADJUST CLUTCH PEDAL TOTAL TRAVEL. DISCONNECT CLUTCH RETRACTING SPRING AND CLUTCH ROD 7B560.
2. INSTALL 0.25 GAUGE PIN AS SHOWN. ON L, LT, AND LTS-800 MODELS, ADJUST ROD 7604 TO DIMENSION SHOWN.
3. ADJUST SPHERICAL NUT 7A525 TO REMOVE ALL LASH BETWEEN THE RELEASE BEARING AND THE CLUTCH FINGERS. TIGHTEN JAM NUT 34987-S2.
4. WITH CLUTCH PEDAL HELD AGAINST ITS STOP, ADJUST CLUTCH ROD 7B560 CLEVIS UNTIL THE CLEVIS PIN FITS FREELY THROUGH THE BAR (7528) OR BELLCRANK (7B585). LENGTHEN THE ROD BY TURNING THE CLEVIS 5 FULL TURNS.
5. REMOVE THE GAUGE PIN AND INSTALL THE CLUTCH ROD 7B560.
6. INSTALL THE RETRACTING SPRING.
7. THIS PROCEDURE SHOULD GIVE A CLEARANCE OF 11/64– 3/16 INCH BETWEEN THE RELEASE BEARING AND THE CLUTCH FINGERS.
8. FREE TRAVEL AT CENTER OF CLUTCH PEDAL PAD SHOULD BE 1-7/8–2-1/8 INCH FOR LN-750 AND 2-1/4–2-1/2 INCH FOR LN-, LNT-, L-, LT-, and LTS-800 MODELS.
9. WITH LINKAGE CORRECTLY SET, ALL SERVICE ADJUSTMENTS ARE MADE AT THE CLUTCH RELEASE LEVER.

PRE-DELIVERY

NEUTRAL SWITCH—AUTOMATIC TRANSMISSIONS

Check, and adjust the switch if necessary, to start engine with shift lever in Neutral and Park position. If equipped with Transmatic transmission, adjust switch to start engine with the shift lever in Neutral position. Refer to the Maintenance Section for the band adjustment procedure.

CHECK AUTOMATIC TRANSMISSION FLUID LEVEL

Check the automatic transmission fluid level following the procedure given in the Lubrication Section of this Part.

FLUID TEMPERATURE LIGHT—TRANSMATIC

Check for proper operation of fluid temperature warning light. Correct as necessary.

RETARDER OPERATION—TRANSMATIC MT-SERIES ONLY

Operate retarder pedal and check for proper function. Correct as necessary.

SHIFT TIMING AND QUALITY

Check for smooth, acceptable and correctly timed up and down shifts, and correct if necessary.

LUBRICATION

LUBRICATE TRANSMATIC TRANSMISSION DETENT STOP ASSEMBLY—MT SERIES ONLY

Apply SAE 10W engine oil sparingly. Wipe off excess lubricant.

LUBRICATE AUTOMATIC TRANSMISSION KICKDOWN LINKAGE

Lubricate all pivot points in the kickdown linkage with lubricant meeting Ford Chassis and Ball Joint Lube specifications (Part 50-03).

CHANGE TRANSMATIC DRIVE TRANSMISSION FLUID AND REPLACE FILTER ELEMENT

MT SERIES TRANSMISSION

1. If the fluid is cold, operate the transmission until a normal operating temperature is reached.

2. Loosen, but do not remove, the screw which secures the filter cover to the transmission pan (Fig. 1).
3. Carefully separate the filter cover from the pan at the bottom edge only. When the drainage is complete, remove the cover, retainer, and filter. Discard the filter and fluid.
4. Install a new filter. Install a new retainer seal ring, filter retainer, a new cover seal ring, cover and strap. Tighten the strap attaching screw (Fig. 1).
5. Slowly pour 9 quarts of the specified automatic transmission fluid into the transmission. Apply the parking brake securely, then start the engine.
6. With the hand throttle, set engine speed at 800-1000 rpm with the selector lever at N.
7. Check the transmission fluid level when the engine reaches normal operating temperature. If necessary, add fluid to bring the level to the ADD FLUID mark.
8. Continue to run the engine at 1000 rpm with the selector lever at 3-6 until the transmission fluid reaches normal operating temperature.
9. Apply the service brakes, and shift the transmission through all ranges.
10. With the engine running and the selector lever at N, check the fluid level. Add fluid if necessary, to bring the level to the FULL mark. Approximately 13 quarts are required if the fluid pan and control valve body have been removed. Total dry capacity for the transmission and cooling system is approximately 19 quarts.

AT-540 TRANSMISSION

1. If the fluid is cold, operate the transmission until a normal operating temperature is reached.
2. Disconnect the filler tube from the transmission pan and allow the fluid to drain.
3. When the fluid has stopped draining, reconnect the filler tube and tighten the fitting securely.
4. Remove the dipstick and pour approximately ten quarts of transmission fluid into the transmission through the filler tube.
5. With the vehicle standing level, apply the parking brake and place the selector lever in N. Operate the engine at idle speed.
6. If the transmission fluid is cold, operate the transmission until normal operating temperatures (150 degrees to 200 degrees F) is reached.
7. When the engine and transmission have reached their normal operating temperatures, shift the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission. Return the selector lever to N.
8. Check the fluid level on the dipstick. The safe operating level is between the ADD and FULL marks on the dipstick. If fluid level is low, add sufficient fluid to bring level to the FULL mark. If level is too high, drain excess fluid to proper level.

CHECK FLUID LEVEL—AUTOMATIC TRANSMISSION (EXCEPT TRANSMATIC)

The automatic transmission is designed to operate with the oil level between the add and full mark on the dipstick at an operating temperature of 150 degrees F to 170 degrees F, and should be checked under these conditions. The operating temperature may be obtained by driving 15 to 20 miles of city type driving with the outside temperature above 50 degrees F. If the transmission is not at an operating temperature of 150 degrees F to 170 degrees F and it becomes necessary to check the fluid level, the transmission may be checked at 70 degrees F to 95 degrees F. Check the fluid level as follows:

TRANSMISSION AT OPERATING TEMPERATURE (150 DEGREES F TO 170 DEGREES F)

1. With transmission in Park P position, engine at curb idle RPM, foot brakes applied and vehicle on level surface, move the transmission selector level through each range, allowing time in each range to engage transmission, return to Park P position, and apply parking brake. **Do not turn off the engine during the fluid level check.**
2. Clean all dirt from the transmission fluid dipstick cap before removing the dipstick from the filler tube.
3. Pull the dipstick out of the tube, wipe it clean, and push it all the way back into the tube. Be sure it is fully seated.
4. Pull the dipstick out of the tube again and check the fluid level. The fluid level should be between the ADD and FULL mark. If additional fluid is required, add enough fluid through the filler tube to bring the level between the ADD and FULL marks on the dipstick. **Do not overfill the transmission,** as this will result in foaming and loss of fluid through the vent and possible transmission malfunction.

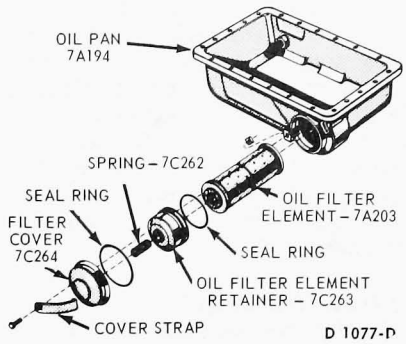

FIG. 1 Transmatic Transmission Fluid Filter Assembly

5. Install the dipstick, making sure it is fully seated in the tube.

TRANSMISSION AT ROOM TEMPERATURE (70 DEGREES F TO 95 DEGREES F)

1. With transmission in Park P position, engine at curb idle RPM, foot brakes applied and vehicle on level surface, move the transmission selector lever through each range, allowing time in each range to engage transmission, return to Park P position and apply parking brake. **Do not turn off the engine during the fluid level check.**
2. Clean all dirt from the transmission fluid dipstick cap before removing the dipstick from the filler tube.
3. Pull the dipstick out of the tube, wipe it clean, and push it all the way back into the tube. Be sure it is fully seated.
4. Pull the dipstick out of the filler tube again and check the fluid level. **For C4 and FMX transmissions,** the fluid level should be between the middle and top holes on the dipstick. If the fluid level is below the middle hole, add enough fluid through the filler tube to bring the level between the **middle hole** and the ADD mark. **For C6 transmissions,** the fluid level should be between the middle and top holes on the dipstick. If the fluid level is below the middle hole, add enough fluid through the filler tube to bring the level between the **middle and top** holes.
5. Install the dipstick, making sure it is fully seated in the tube.

If the transmission fluid level is correctly established at 70 degrees F to 95 degrees F, it will appear between the ADD and FULL marks on the dipstick when the transmission reaches an operating temperature of 150 degrees F to 170 degrees F. This fluid is set between the middle hole and the ADD mark for C4 and FMX transmissions

and between the middle and top holes for the C6 transmission to allow for expansion of the fluid as transmission temperatures rise to normal operating temperatures of 150 degrees F to 170 degrees F.**Do not overfill;**however, if fluid is too low, extreme cold temperatures will contract the fluid, which may result in transmission malfunction.

CHECK TRANSMATIC TRANSMISSION FLUID LEVEL

MT-SERIES TRANSMISSION

1. With the vehicle standing level, apply the parking brake, and place the range selector lever in N. Start the engine.
2. If the transmission fluid is cold, operate the transmission until normal operating temperatures are reached. **Do not operate the hydraulic retarder to warm the transmission fluid. Operating the hydraulic retarder when the vehicle is not moving will aerate the fluid, making an accurate fluid level check impossible.**
3. When the engine and transmission have reached their normal operating temperatures, move the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission.
4. With the hand throttle, adjust the engine speed to 800-1000 rpm with the selector lever at N.
5. Clean around the transmission dipstick cap before removing the dipstick.
6. Twist the dipstick counterclockwise to unlock the cap from the tube. Pull the dipstick out of the tube, wipe it clean, and insert it back into the tube. On a C-Series truck, the dipstick can be removed through the opening in the panel behind the seat back cushion with the cab in its normal position.
7. Remove the dipstick again and check the fluid level. If necessary, add Specified Automatic Transmission Fluid to raise the fluid level to the FULL mark on the dipstick. If the fluid level is more than 5/16 inch above the FULL MARK, drain fluid until the FULL level is obtained.
8. Replace the dipstick in the tube. Turn the cap clockwise to lock it. **Failure to lock the cap may cause** the transmission selector lever in neutral and park.

AT-540 TRANSMISSION

1. With the vehicle standing level, apply the parking brake, and place the range selector lever in N. Operate the engine at idle speed.
2. If the transmission fluid is cold, operate the transmission until normal operating temperature (150 degrees to 200 degrees F) is reached.
3. When the engine and transmission have reached their normal operating temperatures, move the selector lever through all the range positions to make sure that warm fluid is distributed throughout the transmission. Return the selector lever to N.
4. Clean around the end of the fill pipe before removing the dipstick.
5. Check fluid level on dipstick. The safe operating level is between the ADD and FULL marks on the dipstick. If fluid level is low, add sufficient fluid to bring level to the FULL mark. If level is too high, drain excess fluid to proper level.

MAINTENANCE

TRANSMISSION SHIFT LEVER OPERATION

Check and adjust automatic transmission, if necessary, to match transmission range and lever position.

CHECK TRANSMISSION MOUNTINGS

Check the transmission attaching bolts to be sure they are tightened to specifications. Tighten the attaching bolts to specifications, if necessary.

NEUTRAL START SWITCH ADJUSTMENT

F-100-250-350 AND P-350-400-500

1. Loosen the two neutral start switch attaching screws (Fig. 2).
2. Hold the selector lever against the neutral stop.
3. Move the sliding block on the neutral switch to the neutral position. Working from the rear side of the switch, insert an 0.091 inch diameter gauge pin (No. 43 drill) in the gauge pin hole (Fig. 2).

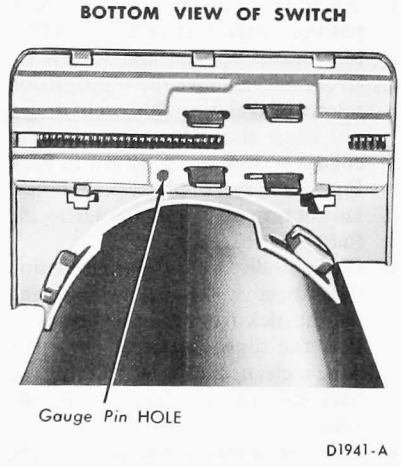

FIG. 2 Typical Neutral Start Switch—F-100-250-350

4. Slide the switch as required to permit the switch actuating lever to contact the switch sliding block.
5. Tighten the two switch attaching screws and remove the auge pin.
6. Check the operation of the switch. The engine should start only with the transmission selector lever in neutral and park.

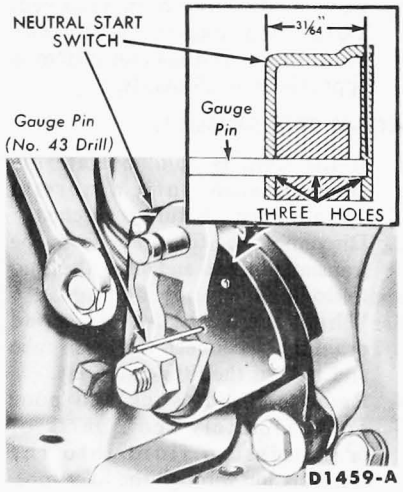

FIG. 3 Neutral Start Switch—Econoline and Bronco

ECONOLINE AND BRONCO

1. With the manual linkage properly adjusted, loosen the two switch attaching bolts (Fig. 3).

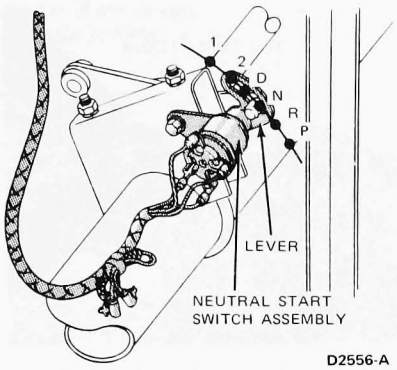

FIG. 4 Neutral Start Switch—P-350-400-500

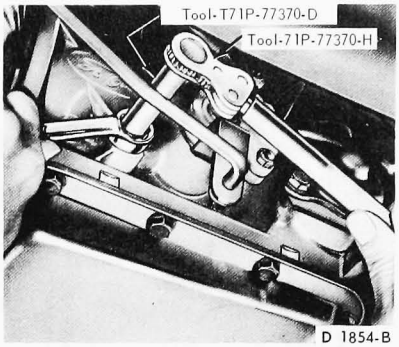

FIG. 5 Intermediate Band Adjustment—C4 Transmission

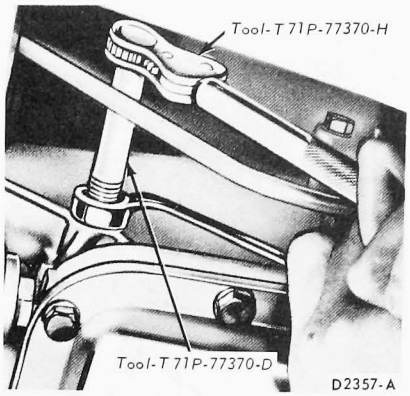

FIG. 6 Low-Reverse Band Adjustment—C4 Transmission

2. Place the transmission manual lever in neutral. Rotate the switch and insert the gauge pin (No. 43 drill shank end) into the gauge pin holes of the switch. The gauge pin has to be inserted a full 31/64 inch into the three holes of the switch (Fig. 3).
3. Torque the two neutral start switch attaching bolts to specification. Remove the gauge pin from the switch.
4. Check the operation of the switch. The engine should start only with the transmission selector lever in neutral or park.

P-350-400-500

1. Place the selector lever in neutral.
2. Loosen the two neutral start switch attaching screws.
3. Move the neutral start switch until the switch lever is in the neutral detent position (Fig. 4). Tighten the attaching screws.
4. Check the operation of the switch in each selector lever position. The engine should start only with the transmission selector level in neutral or park.

CHECK AND ADJUST C-4 AUTOMATIC TRANSMISSION BANDS

INTERMEDIATE BAND

1. Clean all dirt from the band adjusting screw and apply penetrating oil to the adjusting screw threads. Remove and discard the lock nut.
2. Install a new lock nut on the adjusting screw. With the tool shown in Fig. 5, tighten the adjusting screw until the tool handle clicks. The tool is a pre-set torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. **Back off the adjusting screw exactly 1 3/4 turns.**
4. Hold the adjusting screw from turning and torque the lock nut to specification.

LOW-REVERSE BAND

1. Clean all the dirt from the band adjusting screw area and apply penetrating oil to the adjusting screw threads. Remove and discard the lock nut.
2. Install a new lock nut on the adjusting screw. With the tools shown in Fig. 6, tighten the adjusting screw until the tool handle clicks. The tool is a pre-set torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. **Back off the adjusting screw exactly 3 full turns.**
4. Hold the adjusting screw from turning and torque the lock nut to specification.

C6 TRANSMISSION INTERMEDIATE BAND ADJUSTMENT

1. Clean all the dirt from the band adjusting screw area. Remove and discard the lock nut.
2. Install a new lock nut and tighten the adjusting screw to 10 ft-lbs torque (Fig. 7).
3. **Back off the adjusting screw exactly 1 1/2 turns.**
4. Hold the adjusting screw from turning and tighten the lock nut to specification.

CHECK AND ADJUST FMX TRANSMISSION BANDS

FRONT BAND ADJUSTMENT

1. Drain the fluid from the transmission by loosening the pan attaching bolts starting at the rear of the pan and working toward the front. When most of the fluid has drained from the pan, remove the remainder of the attaching bolts. Use a clean drain can equipped with a 100-mesh screen if the fluid is to be reused.
2. Remove the pan, then remove the fluid filter and clip from the transmission. Clean the inside of the pan. Remove all gasket material from the pan mounting face of the case.
3. Loosen the front servo adjusting screw lock nut.
4. Pull back on the actuating rod, and insert the 1/4 inch spacer between the adjusting screw and servo piston stem (Fig. 8). Tighten the adjusting screw to 10 in-lbs torque. Remove the spacer and tighten the adjusting screw an additional 3/4 turn. Hold the adjusting screw stationary and tighten the lock nut securely.
5. Install the transmission fluid screen and clip. Install the pan using a new gasket.
6. Refill the transmission to the proper level with the specified fluid.

REAR BAND ADJUSTMENT

1. Remove all dirt from the adjusting screw threads, then oil the threads.
2. Loosen the rear band adjusting screw lock nut. Using the torque wrench shown in Fig. 9, tighten the adjusting screw until the tool handle clicks. The tool is a pre-set torque wrench which clicks and breaks when the torque on the adjusting screw reaches 10 ft-lbs.
3. If the screw is found to be tighter than wrench capacity (10 ft-lbs torque), loosen the screw and tighten until the wrench clicks and breaks.
4. Back off the adjusting screw 1 1/2 turns. Hold the adjusting screw

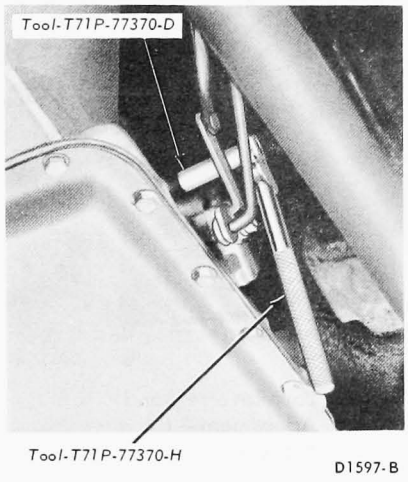

FIG. 7 Intermediate Band Adjustment—C6 Transmission

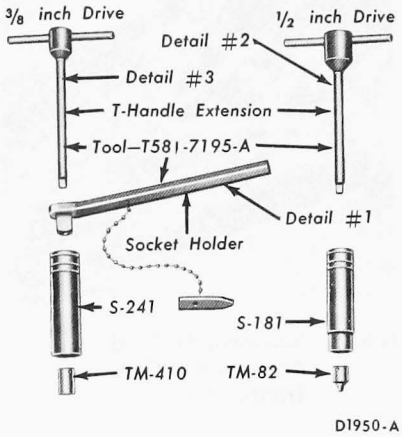

FIG. 8 Front and Rear Band Adjusting Tool—FMX Transmission

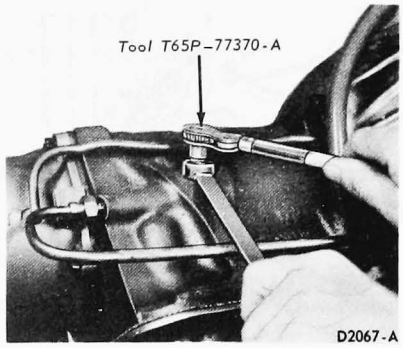

FIG. 9 Adjusting Rear Band—FMX Transmission

stationary and torque the adjusting screw lock nut to specifications. **Severe damage may result if the adjusting screw is not backed off exactly 1 1/2 turns.**

SPECIFICATIONS

Refer to the 1973 Truck Specifications Book or Truck Shop Manual for any specifications or Special Tools not contained in this Section.

TORQUE LIMITS (IN-LBS)

Mechanical	21-06

PRE-DELIVERY

CHECK ENGINE OIL LEVEL

Check the dipstick for the correct quantity of oil. Use only the specified oil. See Part 50-03.

The engine oil level should be above the ADD oil mark and not above the FULL mark.

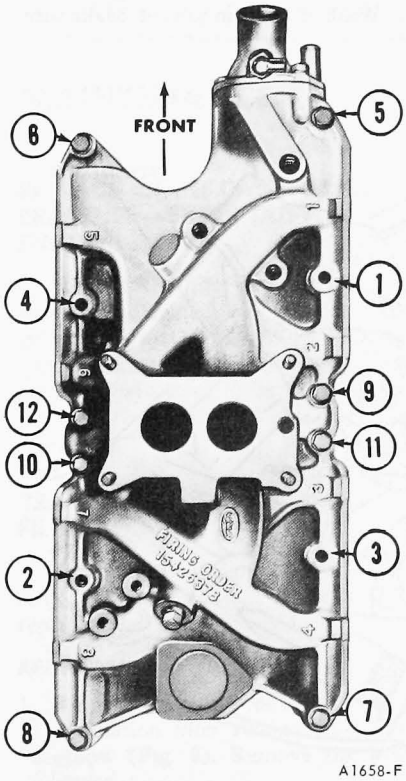

FIG. 1 Intake Manifold Torque Sequence—302 Engine

DRIVE BELTS

Check noise level and belt tension and correct as necessary. Refer to Specifications Section for gasoline engine belt tension specifications. Refer to the applicable manufacturer's service manual for diesel engine belt tension specifications.

TORQUE INTAKE MANIFOLD BOLTS—8-CYLINDER ONLY

Refer to the appropriate illustration for the correct tightening sequence (Figs. 1, 2 and 3). Using a torque wrench, and following the sequence given, tighten the manifold to specifications (Specifications Section).

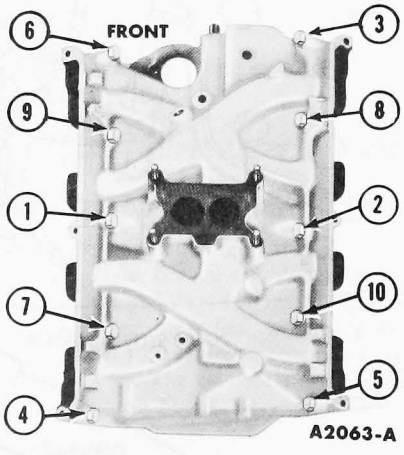

FIG. 2 Intake Manifold Torque Sequence—330, 360, 361, 390 and 391 Engines

Torque bolts evenly, criss-crossing the manifold at the fuel and coolant passage connections.

CHECK AND ADJUST ENGINE GOVERNOR SPEED

Refer to the Maintenance Section of this Part for the governor speed adjustment procedures.

ENGINE PERFORMANCE

Check for smoothness of operation and performance consistent with weight, engine size, and transmission-axle ratio combination.

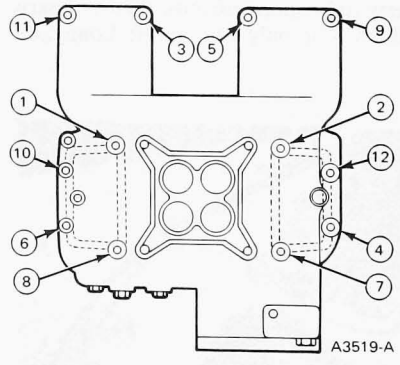

FIG. 3 Intake Manifold Torque Sequence—401, 477 and 534 Super Duty Engines

LUBRICATION

ENGINE OIL AND FILTER—GASOLINE ENGINES

By law, all 1973 U.S. vehicles are equipped with air pollution control systems. To maintain effective operation of these systems to properly protect the engine, use of a high grade motor oil with some new characteristics is essential. Ford 6000 Mile Motor Oil is formulated to meet these requirements. If another brand of oil is used, it must meet Ford Motor Company performance specification, 101-C.

These required oils contain a special additive which neutralizes the corrosive acids (generated in all engines by burning gasoline) which are not completely removed by the required anti-smog emission system controls. In addition, the specified oils have been formulated to keep the crankcase ventilation valve clean and fully operative, so that the emission control (anti-smog) system will operate as designed.

OIL VISCOSITY

From the tables in the Specifications Section, select the viscosity that most nearly matches the expected temperature range of vehicle operation.

USE THE RIGHT OIL FILTER

Proper oil filtration is just as essential as use of good motor oil. The two-stage filtering action of a Motorcraft oil filter has been shown by tests to be more effective than ordinary filters. Use only Motorcraft Long Life oil filter or one of equal quality which meets the Ford Motor Company specifications (Part 50-03).

CHANGE ENGINE OIL

1. Remove the oil pan drain plug, drain oil into a container, then replace the plug.
2. **Install a new filter or element each time the oil is changed.**
3. Fill the crankcase with the specified engine oil. Run the engine at fast idle and check for leaks.

ENGINE OIL FILTER REPLACEMENT

Disposable-Type Oil Filter Assembly—All Except Econoline

1. Place a drip pan under the oil filter. Unscrew the filter from the cylinder block with a filter wrench.
2. Coat the gasket on the new filter with oil. Place the filter in position on the cylinder block (Fig. 4). Hand tighten the filter until the gasket contacts the adapter face; then advance it 1/2 turn.
3. Operate the engine at fast idle, and check for oil leaks. If oil leaks are evident, perform the necessary repairs to correct the leakage. Check the oil level and fill the crankcase if necessary.

Disposable-Type Oil Filter Assembly—Econoline

To remove the oil filter on Econoline models with V-8 engines and power steering, the following instructions are recommended:

1. With the wheels to the full right turn (against stops) position, loosen the oil filter with a strap wrench.
2. Unscrew the oil filter from the engine, turn it to a horizontal position, and let the excess oil drain off.
3. Slide the filter rearward and remove (Fig. 5).

Note: Some effort may be required to slide the oil filter between the engine crossmember and the power steering hoses. This is considered normal.

Replaceable Element Type Oil Filter

The oil filter assembly is shown in Figs. 6 and 7.

1. Place a drip pan under the filter. Remove the filter center bolt, then remove the filter assembly and gasket. Discard the gasket.
2. Remove the filter element, neoprene gasket, spring and seat; then remove the center bolt from the container and the fiber gasket from the bolt. Discard the element and gaskets.
3. Wash all parts in solvent. Make sure

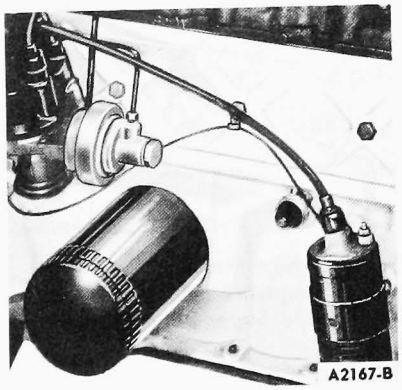

FIG. 4 Oil Filter Installed—Typical

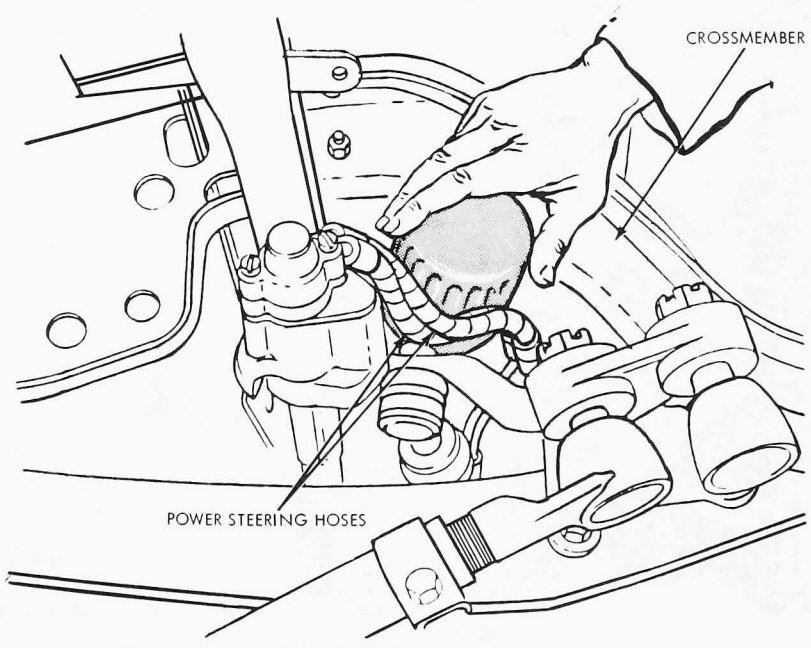

FIG. 5 Econoline Oil Filter Removal—V-8 Engine and Power Steering

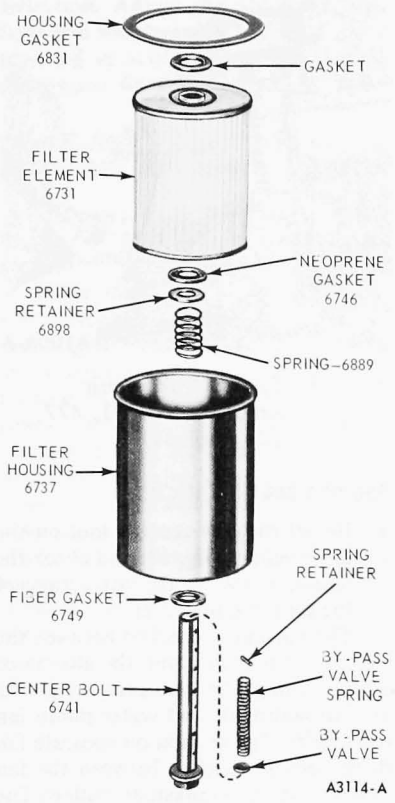

FIG. 6 Typical Replaceable Element—Type Oil Filter Assembly

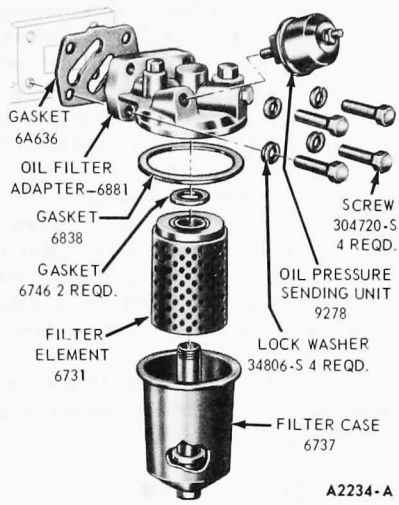

FIG. 7 Cartidge-Type Oil Filter and Adapter Mounting—Heavy Duty

the openings in the bolt are clean.

4. Install the new filter element in the housing, following the instructions furnished with the new element.
5. Clean the cylinder block filter recess. Install a new gasket.
6. Place the filter assembly in position and thread the center bolt into the adapter finger tight.
7. Rotate the filter assembly slightly, in each direction, to make sure the gasket is seated evenly.
8. Torque the bolt to specifications (Specifications Section). **Do not overtorque the bolt.**
9. Add oil to the crankcase, if necessary. Operate the engine at fast idle and check for oil leaks.

MAINTENANCE

REPLACE CRANKCASE FILL CAP BREATHER—SUPER DUTY ENGINES

Replace the filler cap and breather assembly at specified maintenance intervals (Part 50-02). With a closed type crankcase ventilation system, the air hoses will have to be disconnected before removing the filler cap assemblies.

CRANKCASE VENTILATION FILTER

Refer to the Maintenance Schedule for recommended frequency of replacement.

REMOVAL

1. Remove the clip from the crankcase ventilation filter retainer and hose elbow (Fig. 8). Remove the hose elbow.
2. Remove the top of the air cleaner.
3. Remove the filter pack from the air cleaner tray. Remove the filter.

INSTALLATION

1. Replace the filter in the filter retainer. Index the filter pack to the locating slot in the air cleaner.
2. Replace the clip on the filter retainer. Snap the hose elbow into place.
3. Install the air cleaner top.

CLEAN ENGINE OIL COOLER—SUPER DUTY ENGINES

REMOVAL

1. Drain the cooling system.
2. Remove the oil cooler cover and gasket and the oil cooler and gasket.
3. Remove the relief valve plug and gasket; then remove the spring and plunger. The oil cooler assembly is shown in Fig. 9.

CLEANING

Clean the oil cooler as soon as possible after removing it from the engine, or soak it in cleaning solvent until ready to clean. This will prevent hardening and drying of accumulated foreign material.

Immerse the oil cooler in a commercial cleaning solvent and clean the outside of the plates with a stiff bristle brush.

Pressure circulate a standard commercial solvent (at a pressure of

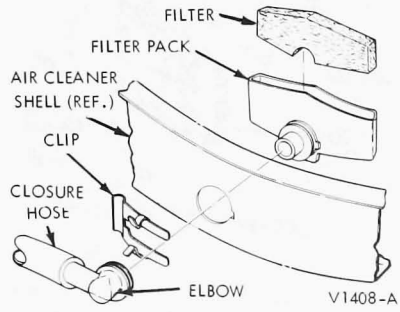

FIG. 8 Crancase Ventilation Filter

approximately 20 psi) through the oil passages of the cooler in the reverse direction of normal flow. Normal flow is from the bottom hole (inlet) to the top hole (outlet). If a circulating pump is not available, soak the cooler in solvent for a few minutes and force the solvent through the oil passages with a plunger or piston-type hand pump. If the oil passages are severely clogged, use an alkaline solution. After cleaning, pressure flush the cooler with clean hot water.

Thoroughly clean the passages in the cover and clean the relief valve assembly. Remove gasket sealer from the cover, oil cooler, and block.

INSTALLATION

1. Install the relief valve plunger (with the open chamber up), spring, gasket and plug in the cover.
2. Place a new cooler gasket, with sealer on both sides, on the block. Position the oil cooler in the block.
3. Place a new cover gasket on the cover with sealer on both sides and install the cover, then tighten the cover bolts to specifications.
4. Open the air bleed valve at the front of the intake manifold and fill and bleed the cooling system.

CLEAN CRANKCASE EMISSION SYSTEM AND REPLACE VALVE

Do not attempt to clean the crankcase ventilation system valve. It must be replaced at the scheduled maintenance interval. The crankcase ventilation system valve is located inside the oil fill cap on vehicles equipped with a closed crankcase system.

The oil filler tube breather cap, located on the valve rocker arm cover should be cleaned at the proper mileage interval. **On a closed crankcase ventilation system, the oil filler tube cap does not filter air; therefore, it does not require cleaning.** Remove the cap and wash it in a low volatility, pretroleum-base solvent. Probe the breather hole(s) to assure removal of any accumulated deposits. Shake the cap dry and install it. **Do not dry with compressed air as air pressure may damage the filter element.**

Clean the crankcase ventilation system connection on the carburetor spacer or intake manifold by probing the inlet nipple with a flexible wire or bottle brush.

Clean the rubber hoses with a low-volatility, pretroleum-base solvent and dry with compressed air.

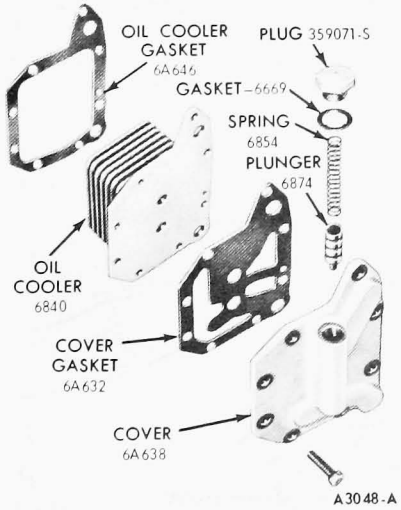

FIG. 9 Oil Cooler Assembly

DRIVE BELT TENSION ADJUSTMENT—GASOLINE ENGINES

Recommended belt tensions are included in the Specifications Section. Check the tension and adjust as necessary. To insure proper tension use Burroughs Belt Tension Checking Tool T63L-8620-A (Fig. 10).

100-350 SERIES TRUCKS

1. Install the belt tension tool on the drive belt(s) (Fig. 10) and check the tension following the instructions of the tool manufacturer.
2. If adjustment is necessary, loosen the alternator mounting bolts and move the alternator adjusting arm bolt. Move the alternator toward or away from the engine until the correct tension is obtained. Remove the gauge. Tighten the alternator adjusting arm bolt and the mounting bolts. Install the tension gauge and check the belt tension.

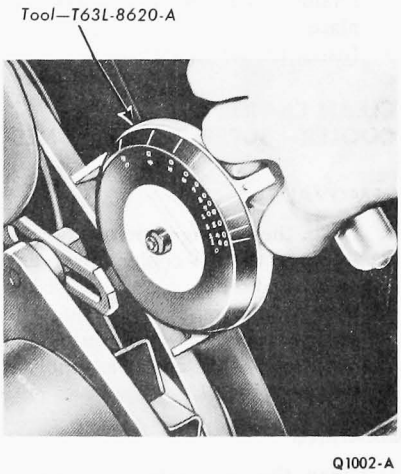

FIG. 10 Checking Drive Belt Tension

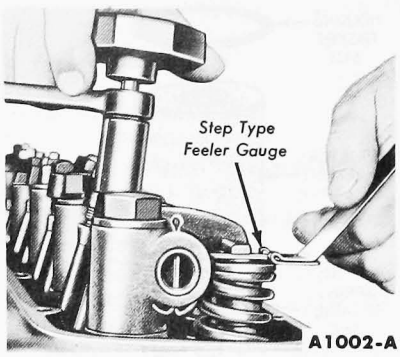

FIG. 11 Typical Valve Lash Adjustment—401, 477, 534 Engines

500-900 SERIES TRUCKS

1. Install the belt tension tool on the drive belt(s) (Fig. 10) and check the tension following the instructions of the tool manufacturer.

The tension is checked between the water pump pulley and the alternator pulley on single or double fan drive belts and all alternator and water pump fan drive belts. The tension on spearate fan drive belts is checked between the fan pulley and the crankshaft pulley. The tension of the air compressor drive belt is checked between the compressor pulley and the fan pulley or the crankshaft (C-Series).

2. If adjustment is necessary, follow the applicable procedure.

SINGLE OR DOUBLE FAN BELTS

Loosen the alternator mounting bolts and the alternator adjusting bracket bolt. Move the alternator generator toward or away from the engine until the correct belt tension is obtained. Tighten the alternator mounting bolts and the adjusting bracket bolt before checking the tension.

SEPARATE FAN BELT

Loosen the fan bracket mounting bolts. Slide the bracket up or down until the correct belt tension is obtained. Tighten the bracket bolts before checking the tension.

On a truck equipped with an air compressor, it may be necessary to loosen the compressor drive belt in order to obtain proper fan drive belt adjustment. Adjust the compressor drive belt after the fan drive belt adjustment is complete.

AIR COMPRESSOR BELT

Loosen the air compressor mounting bolts and slide the compressor in its bracket until the correct tension is obtained. Tighten the compressor mounting bolts before checking the

deflection. **Adjust the air compressor drive belt whenever the fan drive belt is adjusted or replaced. Adjust the air compressor drive belt last.**

CHECK AND ADJUST VALVE LASH (401, 477 AND 534 C.I.D.)

It is very important that the valve lash be held to the correct specifications because:

If the lash is set too close, the valve will open too early and close too late, resulting in rough engine idle. Burning and warping of the valves will occur also because the valves cannot make firm contact with the seats long enough to cool properly. If the lash is excessive, it will cause the valve to open too late and close too early causing valve bounce. In addition, damage to the camshaft lobe is likely because the tappet foot will not follow the pattern of the camshaft lobe causing a shock contact between these two parts.

1. Be sure the engine is at normal operating temperature before attempting to set the valve lash.
2. With the engine idling, set the valve lash (Fig. 11) using a step-type feeler gauge only (go and no go). The final (hot) intake and exhaust valve lash settings are listed in the Specifications Section.

CHECK ENGINE MOUNTINGS

Occasionally, the engine mountings should be visually checked. If the vehicle is operated on rough terrain, this check should be made frequently. If the mounting bolts are loose, torque them to specifications (Specifications Section). If the insulators are worn or frayed, replace them.

VACUUM GOVERNOR ADJUSTMENT

1. Connect a tachometer to the engine.
2. Operate the engine until normal operating temperature has been reached.

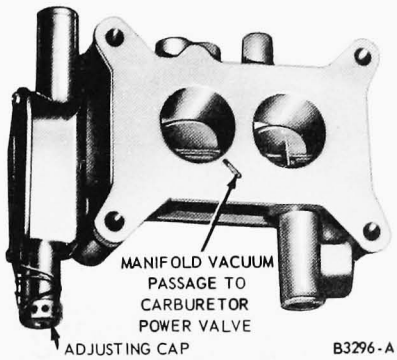

FIG. 12 Typical Velocity Governor

3. Operate the engine at wide open throttle and note the engine speed registered.
4. Stop the engine and remove the adjusting hole plug from the controlling unit housing.
5. With the ignition switch off, crank the engine until the governor adjusting nut is aligned with the adjustment hole.
6. Turn the adjusting nut clockwise to increase speed and counterclockwise to decrease speed. One full turn of the adjusting nut will change top speed about 150 rpm.
7. Repeat the above procedure until the proper top speed is reached.
8. Install the adjusting hole plug and tighten it securely.
9. Attach a new locking wire and lead seal to the adjusting hole plug and the adjacent fin.

VELOCITY GOVERNOR ADJUSTMENT

CONVENTIONAL AND COOLANT HEATED VELOCITY GOVERNORS

Connect a tachometer to the engine. With the engine at normal operating temperature, operate the engine at wide open throttle and compare the rpm with the operating range of the governor. The operating range is stamped on the governor plate.

If governed speed is within range, stop the engine and remove the tachometer.

If adjustment is required or desired, remove the governor seal (Fig. 12). To increase rpm, turn the cap counterclockwise. To decrease rpm, turn the cap clockwise. When adjustment is complete, stop the engine, seal the cap, and remove the tachometer.

COMPENSATING GOVERNOR

If the truck is going to be operated at a consistent altitude, adjust the governor by following the Constant Altitude Adjustment Procedure.

If the truck is going to be operated at varying altitudes above 2000 feet, adjust the governor by following the Constant Altitude Adjustment Procedure.

If the truck is going to be operated at varying altitudes adjust the governor by following the Varying Altitude Adjustment Procedure.

CONSTANT ALTITUDE ADJUSTMENT

1. Cut the governor seal wire and remove the adjusting cap (Fig. 12). **Do not rotate the adjusting cap during removal.**
2. Use a mirror and a light to observe the position of the slots in the adjusting bushing (Fig. 13).
3. Hold tool T64T-12450-A in the proper position to engage the adjusting bushing slots (Fig. 13), and carefully insert the hex-shaped center post of the tool in the hex-head of the adjusting screw. Push the tool inward until the tangs on the tool engage the slots in the adjusting bushing. **If the tool will not engage in the adjusting bushing slots, note the position of the tool and rotate the tool slightly in either direction until engagement is achieved. If it is necessary to rotate the tool more than 1/6 turn (1 flat of the hex head) to accomplish engagement, rotate the tool back to its insertion position and pull the tool out. Rotate the tool 1/6 turn in the direction required to achieve engagement and re-insert it.**
4. The altitude adjustment table specified the amount from the factory setting that Tool T64T-12450-A should be rotated to adjust the velocity governor for altitude operation. For an increase in the average altitude of operation, rotate the tool the specified amount in the counterclockwise direction.
5. Remove the tool and install the adjusting cap. **Do not turn the adjusting cap.**
6. Install a tachometer and check and adjust the no-load setting of the governor. The no-load setting should be 3900 rpm at the trucks operating altitude. If the altitude adjustment was done properly, the load setting at the trucks operating altitude should be 3600 rpm.

If the governor is being adjusted at an altitude above the truck anticipated operating altitude, the load and no-load speeds should be slightly above 3600 and 3900 rpm respectively. If the governor is being adjusted at an altitude below the truck anticipated operating altitude, the load and no-load should be slightly below 3600 and 3900 rpm respectively.

If the load rpm is below the specified rpm (3500 at sea level and 3600 at operating altitudes above 2000 feet), insert the tool by following step 3 and turn it counterclockwise. Remove the tool, insert the adjusting cap and adjust the no-load setting. Check the load setting and adjust again if necessary.

If the load rpm is above the specified rpm (3500 at sea level and 3600 at operating altitudes above 2000 feet), insert the tool by following step 3 and turn it clockwise. Remove the tool, insert the adjusting cap and adjust the

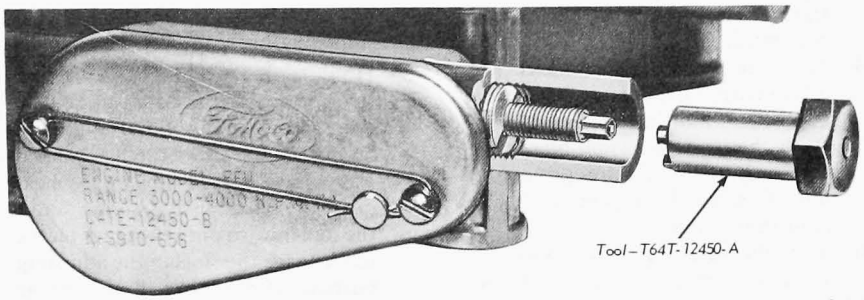

FIG. 13 Altitude Compensation Adjustment

no-load setting. Check the load setting and adjust again if necessary.

7. Remove the tool and install the adjusting cap.
8. Seal the adjusting cap to the governor body (Fig. 12) using the service governor seal wire and lead seal.

VARYING ALTITUDE ADJUSTMENT

This adjustment is made on trucks that are operating between altitudes at or near sea level and altitudes above 2000 feet.

1. Adjust the governor to 3800 rpm (no-load) for sea level operation (this is only necessary if the governor has been adjusted after the truck has left the factory).
2. Using the adjusting cap only, adjust the no-load speed for 4100 rpm at the anticipated altitude (Fig. 14) by turning the adjustment cap 1/4 turn in the clockwise direction for each 1000 foot difference between the adjusting and maximum anticipated operating altitudes.

If the maximum operating altitude of the truck is lower than the altitude at which the adjustment is being made, adjust the no-load speed to 4100 rpm with the adjustment cap.

Average Operating Altitude—Feet	Amount of Tool Rotation
2000	1/3 turn (120°)
3000	1/2 turn (180°)
4000	2/3 turn (240°)
5000	5/6 turn (300°)
6000	1 turn (360°)

+60 or 1/6 turn rotation is equivalent to one flat of the tool hex head.

CY1174-A

FIG. 14 Altitude Adjustment Table

MECHANICAL GOVERNOR ADJUSTMENT

Refer to Fig. 15 for governor speeds (no-load rpm) for gasoline engines.

1. Disconnect the throttle control rod at the carburetor.
2. Loosen the top nut on the primary spring adjusting eye bolt.
3. Tighten the bottom nut finger tight, then turn it in two additional turns to pre-load the spring. Tighten the top nut.
4. Move the throttle to the wide open position and connect the governor throttle control rod to the carburetor control arm.
5. Adjust the governor throttle control rod so that the governor throttle control auxiliary lever is full forward. This is the wide open throttle position. Next, shorten the rod one full turn. This will position the throttle plates slightly off wide open position and will avoid compression of the control rod linkage.
6. Check the accelerator linkage to be sure that wide open throttle position is achieved when the accelerator pedal is depressed to the floor. Be sure that the accelerator rod or cable is attached to the proper hole in the throttle lever.
7. Check the operation of the choke plate from the full open to the full closed position for proper adjustment and freedom of operation. **On a C-Series truck, the choke plate will not close completely when the choke knob is pulled all the way out.**

If there is any bind in the choke cable on a C-Series truck, examine the cable for sharp or reverse bends. Be sure the end of the cable is bent downward to prevent interference with the bottom of the air cleaner, as interference will restrict the opening of the choke plate.

8. To adjust the speed, operate the engine (with the parking brake applied) until normal operating temperature has been reached. Depress the throttle to the full wide open position and adjust the speed by increasing the tension of the governor main spring to increase the rpm, and by decreasing the tension to decrease the rpm.

Sensitivity of the governor can be sharpened by installing the governor spring in the hole closest to the governor lever arm pivot. Adjust the governed speed after changing the spring position.

OIL VISCOSITY VS. TEMPERATURE RECOMMENDATIONS—GASOLINE ENGINES

BRONCO, ECONOLINE, CLUB WAGONS, F-100 THRU -350 M- AND P-SERIES

When you change or add oil, you should select oil with the proper specifications and with the viscosity, selected from the table shown in the Specifications Section which most closely matches the temperature range you expect to encounter for the next 6 months or 6,000 miles.

F-500 THRU -750 AND B-, C-, L-, AND W-SERIES

When you change or add oil, you should select oil with the proper specifications and with the viscosity, selected from the table shown in the Specifications Section, which most closely matches the temperature range you expect to encounter for the next 4 months or 4,000 miles.

SPECIFICATIONS

MULTI-VISCOSITY OILS

When Outside Temperature is Consistently	Use SAE Viscosity Number
Below +32°F	[†] 5W-30
−10°F to +90°F	10W-30
−10°F to +90°F (or above)	10W-40
Above +10°F	20W-40

SINGLE VISCOSITY OILS

When Outside Temperature is Consistently	Use SAE Viscosity Number
−10°F to +32°F	10W
+10°F to +60°F	20W-20
+23°F to +90°F	30
Above 60°F	40

[†] Where sustained driving and/or high speed operation above 60 MPH is anticipated, use the next heavier viscosity oil.

CY1465-A

When Outside Temperature is Consistently	Use SAE Viscosity Number
Below −10°F	[†] 10W
−10°F to +60°F	20W-20
+32°F to +90°F	30
Above +60°F	40

[†] Where sustained driving and/or high speed operation above 50 MPH is anticipated, use 20W-20.

For best performance, use Service Classification "SE" straight viscosity oils.

FORD V-8 DIESEL ENGINES

LUBRICATION

LUBRICATE ACCELERATOR LINKAGE

Lubricate the friction points of the accelerator linkage with the specified lubricant (Part 50-03) at the recommended mileage interval.

LUBRICATE ELECTRIC STARTING MOTOR

Add a few drops of clean SAE 30 weight lubricating oil to cranking motor bearings.

ENGINE OIL LEVEL

FORD V-8 DIESEL

Keep the oil level above the ADD 3 qts. mark.

FORD V-8 DIESEL ENGINES

CHANGE ENGINE OIL AND FILTERS

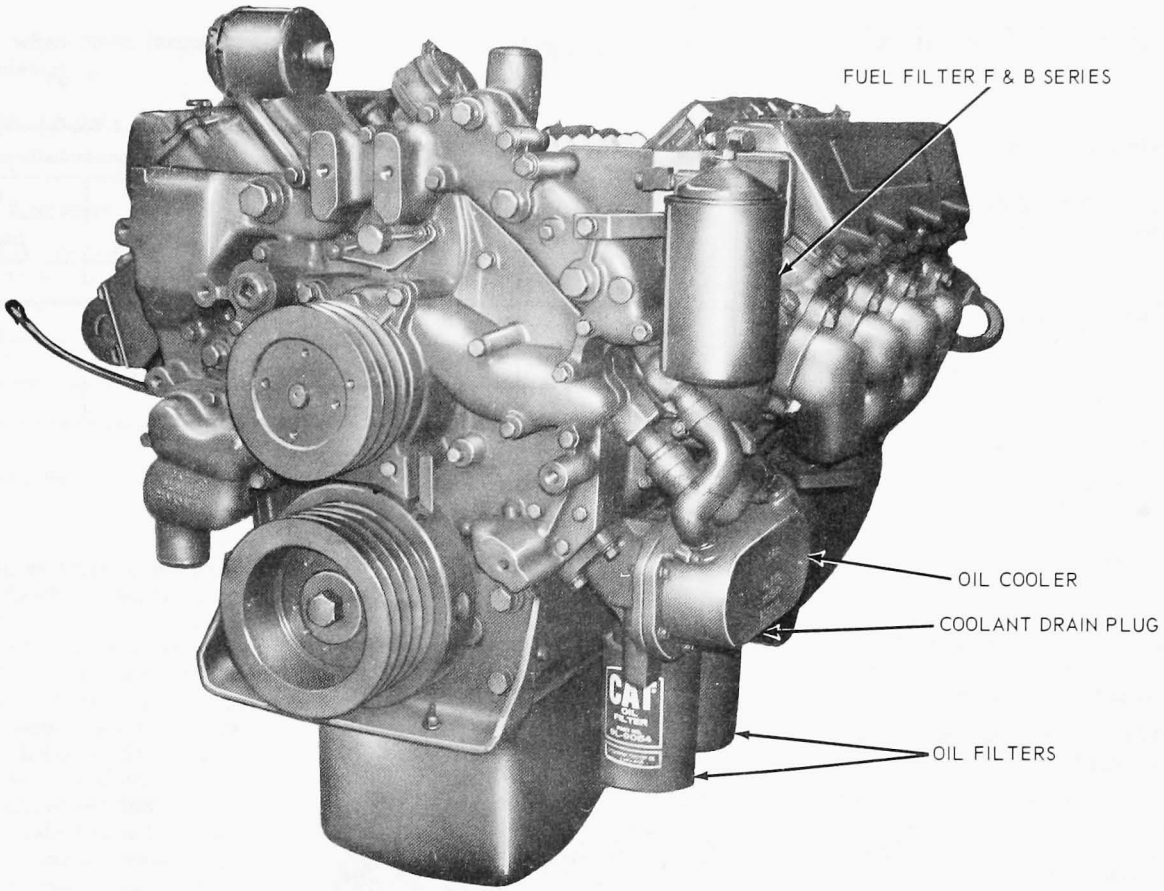
Normal crankcase oil change period is every 6,000 miles when fuel sulphur content is 0.4 or less. When sulphur content is 0.4 to 1.0, reduce interval one-half. If sulphur content is above 1.0, reduce interval to one-fourth of the normal interval.

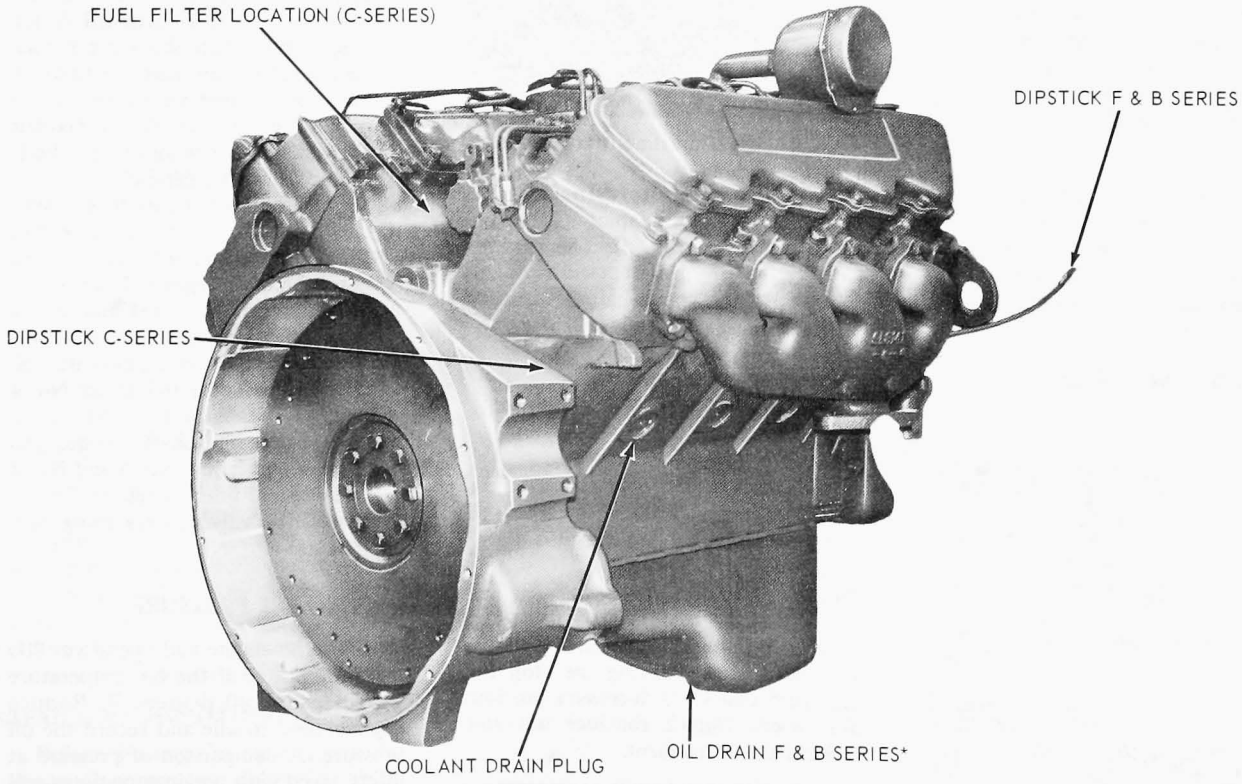
Make the initial oil and filter change after the first 500 miles of operation for a reconditioned engine.

Filters are spin-on, throw-away units. They should be changed every 6,000 miles, regardless of oil change.

Drain the crankcase while the engine is warm.

1. Position a drain pan under the engine drain and the oil filters.
2. Remove the engine crankcase drain plug.
3. Unscrew and remove the two oil filters (Fig. 1). A filter wrench may be used to remove the filters but not to install them.
4. Coat each filter gasket surface with a film of clean engine oil and install the filters. Tighten each filter by hand until the gasket contacts the base, and then tighten 1/2 turn further.
5. Replace the crankcase drain plug.
6. Fill the crankcase with oil shown in owner's handbook.
7. Operate the engine until the oil is warm and oil pressure normal; then check for leaks.
8. Check the engine oil level on the dipstick and add oil if necessary to bring level up to the FULL mark.





*OIL PAN REVERSED ON C-SERIES

FIG. 1 Ford V-8 Diesel Engine Service Points

Y 1093-A

FORD V-8 DIESEL ENGINES

MAINTENANCE

CHECK TORQUE OF ENGINE MOUNTING BOLTS

Use a ft-lb torque wrench and check the torque effort against the specifications for this engine. Refer to Part 22-05 of the 1973 Truck Shop Manual for procedures and specifications.

CHECK AIR INLET PIPING

Check air intake piping from air cleaner to intake manifold. Check for loose clamps or connections, cracks, punctures, or tears in hose or tubing, collapsing hose, or other damage.

Tighten clamps or replace parts as necessary to insure an airtight air intake system. Make sure that all air goes through the air cleaner.

CHECK ENGINE HIGH AND LOW IDLE SPEED

Check the engine high (governed no-load) rpm and low idle rpm per Fig. 2. Use of a direct-reading tachometer is recommended.

If the high idle or low idle rpm is not to specifications, free up or adjust the throttle linkage before making any adjustment of the governor settings. The idle settings, both high and low, are adjusted at the factory and any deviation from specifications should be due to the throttle linkage assembly or operation.

If throttle linkage adjustment will not correct the idle speeds to specifications, follow the procedure given below to adjust both high and low idle. **Only qualified personnel should perform this operation.**

HIGH AND LOW IDLE RPM

Check the engine rpm with an accurate tachometer. Install the tachometer on the adapter located on the front cover (Fig. 3). The reading taken at this point, with a 1:1 tachometer, will be one-half engine rpm.

FIG. 2 Tachometer Adapter Location

Model	Engine Speed – RPM (Hydraulic Governor)		
	High Idle	Full Load	Low Idle (+0, –10 RPM)
150	3380	3200	525
175	3410	3200	525
200	3255	3000	525
225	3040	2800	525

CY1177-B

FIG. 3 Ford V-8 Diesel Idle RPM

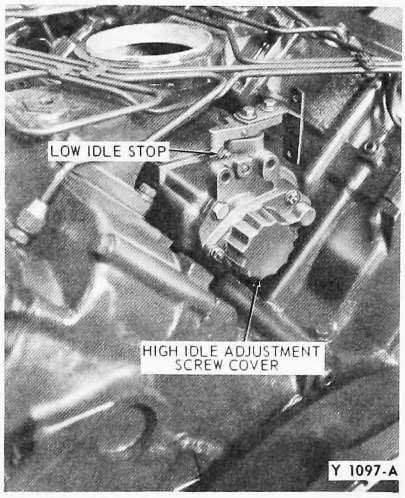


FIG. 4 Idle Adjustment Locations

Remove the high idle adjustment screw cover from the rear of the governor. Turn the high idle adjusting screw (Figs. 4 and 5) clockwise to increase or counterclockwise to decrease high idle speed.

If the adjusting screw requires alignment to install the cover, turn the screw in a clockwise direction the minimum distance required for installation.

Adjust low idle speed by loosening lock nut (Fig. 4) and turning the adjustable stop. Turning the stop IN decreases and OUT increases the low idle speed. Tighten the lock nut and recheck the adjustment.

VALVE CLEARANCE ADJUSTMENT

Valves on this engine are adjusted cold. Make sure that the engine has been stopped for at least twenty minutes before checking or adjusting the valve clearance.

1. Remove both valve covers.
2. Refer to Fig. 6 for cylinder and valve arrangement. Set No. 1 piston on top center of the compression stroke by rotating the crankshaft until the timing mark on the damper is aligned with the timing pointer and number 1 and number 2 exhaust and inlet valves are closed. The rocker arms should be free and each push rod at its lowest point.
3. Loosen the valve adjusting screw lock nuts. Use a standard feeler gauge and adjust the valve rocker arm to valve stem clearance to 0.025 inch for exhaust valves and 0.015 inch for inlet valves (Fig. 7). Tighten the adjusting screw lock nuts. Check the adjustment clearance.
4. Adjust the remaining valves using the procedure above. Use the following sequence: Rotate the crankshaft 180 degrees clockwise (as viewed from the front) and adjust No. 7 and No. 3 exhaust and inlet valves. Rotate the crankshaft 180 degrees clockwise and adjust No. 4 and No. 5 exhaust and inlet valves. Rotate the crankshaft another 180 degrees and adjust No. 6 and No. 8 exhaust and inlet valves.
5. Install the valve covers using new gaskets.

RECORD OIL PRESSURE

Start the engine and operate at 800 to 1000 rpm until the oil temperature gauge reads 140 degrees F. Reduce engine speed to idle and record the oil pressure. A comparison of pressure at idling speed with previous readings will give an indication of progressive wear of lubricating oil pump, bearings, shafts, etc. These readings are more accurate

and reliable when taken immediately after an oil change.

CHECK AND ADJUST DRIVE BELT TENSION

DRIVE BELT TENSIONS

Used belt tension applies to any belt in operation more than ten minutes. To insure proper tension use Burroughs Belt Tension Checking Tool T63L-8620-A. Belts installed in pairs should be replaced in pairs. Belt tension specifications are given at the end of this Part.

ALTERNATOR AND WATER PUMP BELTS

Loosen the alternator mounting bolts and the adjusting bracket bolt. Move the alternator toward or away from the engine until the proper tension is obtained between the water pump pulley and the alternator pulley. Tighten the alternator adjusting bracket bolt and the mounting bolts.

AIR COMPRESSOR BELT

Loosen the air compressor mounting bolts. Slide the compressor in its mounting bracket to obtain the recommended tension between the compressor pulley and the fan pulley (crankshaft damper on a C-Series truck). Tighten the compressor mounting bolts. The air compressor belt should be adjusted whenever the fan belt is adjusted or replaced. Adjust the air compressor belt last.

CHECK RADIATOR COOLANT LEVEL

The coolant level should be maintained at approximately one inch below the filler neck of the radiator.

On L-Series with crossflow radiators, fill until the coolant is 1 inch from the top of the tank-engine cold. **(Caution—Do not operate engine if coolant level is below sight glass).**

CHECK CONDITION OF COOLANT

Coolant water should be soft and free from scale-forming minerals. Add rust inhibitor if necessary. During freezing weather add sufficient ethylene glycol base anti-freeze to the coolant to prevent freeze-up. Do not add rust inhibitor to an anti-freeze solution containing its own rust inhibitor.

CLEAN COOLING SYSTEM

Before cleaning this cooling system, refer to the appropriate Caterpillar Shop Manual for instructions and precautions.

To drain the system: Open radiator drain cock. Remove plugs from the

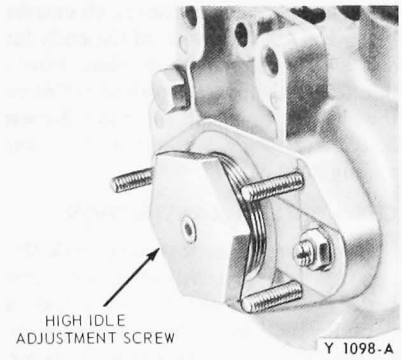

FIG. 5 High Idle Adjustment Screw

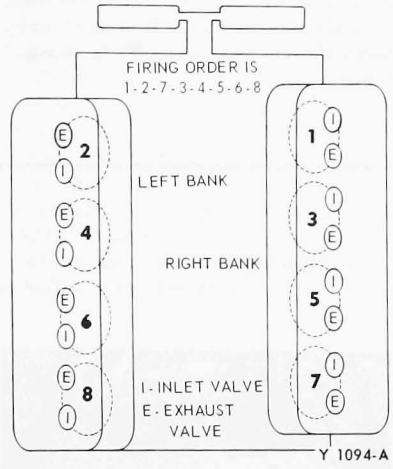

FIG. 6 Cylinder and Valve Arrangement

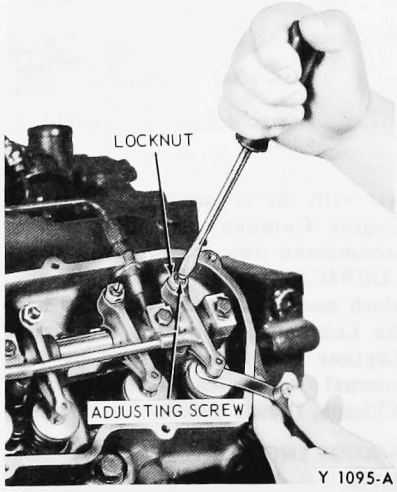

FIG. 7 Adjusting Valve Lash

engine block. Remove plug from the thermostat housing. Remove plug from the oil cooler.

DRAINING AND FILLING THE COOLING SYSTEM

To drain the radiator, open the drain petcock at the bottom of the radiator and drain the coolant into a container to prevent loss of anti-freeze. The radiator will drain faster if the filler cap is removed.

To drain the cylinder block, open the drain cocks at the thermostat housing and oil cooler, and remove the drain plugs from the rear of the cylinder block (one on each side).

To fill the cooling system, install the cylinder block plugs and close the drain cocks at the radiator, thermostat housing and oil cooler. Pour the coolant into the radiator. Operate the engine until operating temperature is reached and check the coolant level.

CHANGE CRANKCASE BREATHER

Dry-type crankcase breathers containing a chemically treated paper element are used on naturally-aspirated engines. Install new elememt— **Do not attempt to clean. Do not use on engines with pressurized systems.**

CLEAN OR REPLACE AIR CLEANER ELEMENT

Cleaning With Compressed Air

1. Direct a jet of clean, dry air from the inside of the filter element perpendicular to the pleats. **Pressure at air nozzle must not exceed 100 psi.**
2. Move the air jet up and down along the pleats, slowly rotating the element until no more dust is being removed. **Be certain that the element is not ruptured by the nozzle or the air jet.**

Cleaning With Water

The elements can be cleaned by washing with water and a good non-sudsing detergent. Direct a jet of clean, dry air from the inside of the filter element. When the loose dust and soot have been removed, the element is ready to be washed.

1. Dissolve the detergent in a small amount of cool water.
2. Add warm (approximately 100 degrees F) water to get the proper proportions of detergent and water (about one cup of detergent to five gallons of water).
3. Soak the element in the solution for at least 15 minutes.
4. Agitate the element for about 2 minutes to loosen the dirt.

Never use gasoline or solvents to clean elements.

5. Rinse the element with clean water until the water coming through the element is clean. Water pressure from a hose or tap should not be over 40 psi. Air-dry the element thoroughly before using.

Mechanized drying methods can be used. However, heated air (maximum

temperature 180 degrees F) must have some circulation. **Do not use light bulbs for drying elements.**

6. After cleaning the filter element, using either air or water, inspect the element for damage. Look for dust on the clean air side, the slightest rupture, or damaged gaskets. A good method to detect ruptures in the element is to place a light inside the element and look toward the light from the outside. Any hole in the element, even the smallest, will pass dust to the engine and cause unnecessary wear.

AIR CLEANER BODY CLEANING AND INSPECTION

Before re-installing the filter element, remove any foreign material (leaves, lint or other foreign matter) that may have collected inside the air cleaner body. Inspect the inside of the body for dents or other damage that would interfere with air flow or with the fins on the element or inside the body. Repair body dents, being careful not to damage sealing surfaces.

CHECK INLET AIR RESTRICTION

The air cleaner furnished with this engine is equipped with an air restriction indicator. Check the air cleaner periodically, judging the service period by the amount of exposure to dusty air. If air inlet restriction exists, the red signal will rise in the viewing window and stay there. If restriction is indicated, remove the air cleaner element and wash or replace it, depending on how many times the air cleaner has been washed previously.

Reset the restriction indicator when servicing the air cleaner.

PRIMING THE FUEL SYSTEM

If air is trapped in the fuel system, the diesel engine either will not start, or will misfire. Loosen the line nut on the fuel line between the fuel filter and the fuel injection pump housing. Operate the starter until the flow of fuel from the filter is continuous and free of bubbles. Tighten fuel line nut. If the engine continues to misfire or smoke, further bleeding is necessary. While the engine is running, loosen each fuel line nut (at the injector) and allow the fuel to flow until it is free of air bubbles. Then tighten the fuel line nut.

CUMMINS DIESEL ENGINES

LUBRICATION

LUBRICATE ACCELERATOR LINKAGE

Lubricate the friction points of the accelerator linkage with the specified lubricant (refer to the Lubricants Chart in Part 50-03) recommended mileage interval.

LUBRICATE ELECTRIC STARTING MOTOR

Add a few drops of clean SAE 30 weight lubricating oil to cranking motor bearings.

ENGINE OIL LEVEL

CUMMINS DIESEL

Keep the oil level between the L and H marks on the dipstick.

CUMMINS DIESEL ENGINES

Cummins Engine Company, Inc., recommends that owners of Cummins Diesels give special consideration to use of heavy duty oils developed for use in diesel engines. Under normal conditions, the oil used should meet the requirements of U.S. Military Specifications MIL-L-2104-B for normally aspirated engines, and MIL-L-2104-B/MIL-L-45199-B for turbocharged or supercharged engines. The responsibility for meeting these specifications, the quality of the product and its performance must necessarily rest with the oil supplier. Cummins Engine Company, Inc., does not recommend any specific brand of LUBRICATION OIL. Many brands which meet specifications are listed in the Lubricating Oils for Industrial Engines booklet published by the Internal Combustion Engine Institute (Chicago, Illinois 60606).

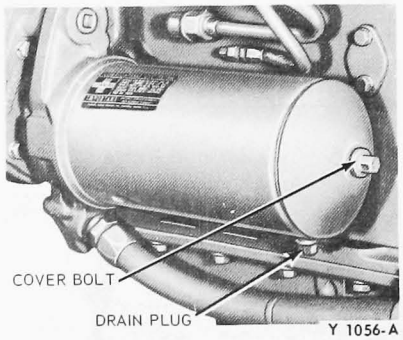

FIG. 8 Horizontal Lubricating Oil Filter

FIG. 9 Examining Oil Filter Bag

CHANGE ENGINE OIL AND REPLACE FILTER

Engine Oil

The kind of oil used, the efficiency of the filtering system and the condition of the engine must be considered in determining when oil needs changing.

The schedule for oil changes is based on average crankcase and filter capacity when both full-flow and by-pass filters are used.

If a by-pass filter is not used, the oil change period must be reduced by one-third.

The safest method for determing oil change is by lubricating oil analysis.

On engines equipped with double sump oil pans, both sumps must be drained when changing oil.

Full-Flow Oil Filter Replacement

1. Drain full-flow lubricating oil filters on all models by removing drain plug (Fig. 8).
2. Loosen filter cover bolt carefully. **The element contains a spring which will separate the head and case when capscrews are loosened. Do not remove case.**
3. Turn filter bag inside out and inspect for bearing metal, grit, etc., (Fig. 9). If metal is found in the bag, an inspection of all connecting rod and

main bearings should be made **at once. Inspect spool gaskets, bag clamp, and spacer mat. If they are not in good condition, replace with new parts.**

Do not attempt to wash and re-use filter bag.

4. Clean all parts thoroughly except bag, gaskets and O-rings.
5. Install a new filter bag as shown in Fig. 10.
6. Insert element, spring end down, in filter case; positioning case to cover with new O-ring(s) and tighten capscrews to secure.

Make certain cover capscrews are tightened evenly to assure a good seal between cover and case.

7. Add approximately one gallon of clean lubricating oil to fill filter case.
8. Check engine oil level after operation; bring level to H mark to replace oil absorbed by new element.

PAPER-TYPE OIL FILTER

If paper element is used by by-pass filter (Fig. 11), change at specified interval. If no by-pass filter is used reduce change by one-third.

1. Remove drain plug from filter case and allow oil to drain.
2. Loosen center bolt and remove filter case from filter head. Some filters use the same case as the bag-type element and should be disassembled in a like manner.
3. Withdraw filter element, inspect, then discard.

Inspect for metal particles. If metal is found, a check of connecting rods and main bearings should be made at once.

4. Remove seal ring from filter head and discard.
5. Check filter case thoroughly.
6. Check to make sure element end seals are in place and install new element over pilot valve assembly.
7. Position new seal ring in place; assemble filter case to head and tighten center bolt (if used) to 30-35 ft-lbs.
8. Check oil level. Run engine and check for leaks.
9. Recheck engine oil level; add oil as necessary to bring oil level to H mark on dipstick.

Always allow oil to drain back to oil pan before checking level.

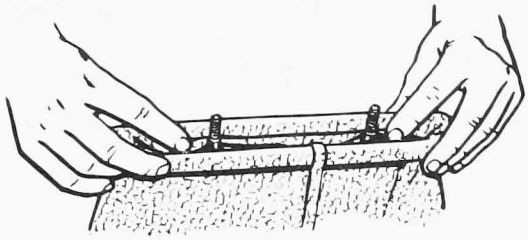
CHANGE BY-PASS OIL FILTER ELEMENT

Change by-pass filter elements on engines so equipped as follows:

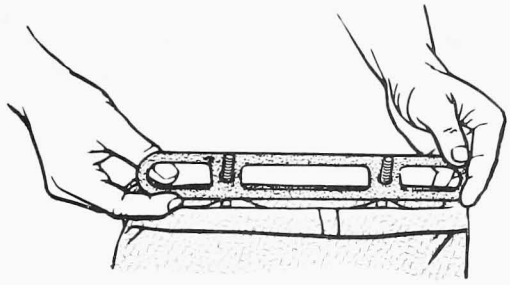
Never use a by-pass filter in place of a full-flow filter.

1. Remove drain plug from bottom of housing and drain oil.
2. Remove clamping ring capscrew and lift off cover.
3. Unscrew pack hold-down assembly; lift out element and hold-down assembly (Fig. 12). Discard element.
4. Clean housing and hold-down assembly in solvent.
5. Inspect hold-down assembly spring and seal. Replace if damaged.
6. Inspect drain plug and connections. Replace plug.
7. On the Cummins by-pass filter, check orifice plug inside oil outlet connection; blow out with air jet to make sure orifice is open and clean.

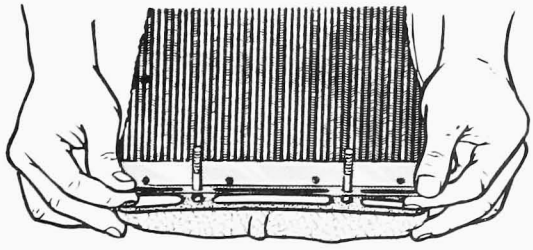
1. Install ring in filter bag with studs protruding. Fold top of bag inward over ring about 1/2 inch; tuck bag snugly around ring stud bases to assure good seat.



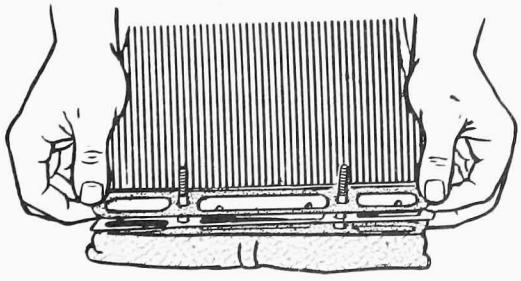
2. Install gasket over studs and against bag.



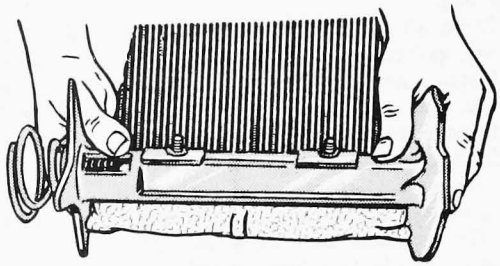
3. Install retainer attached to wire mesh spacer over studs.



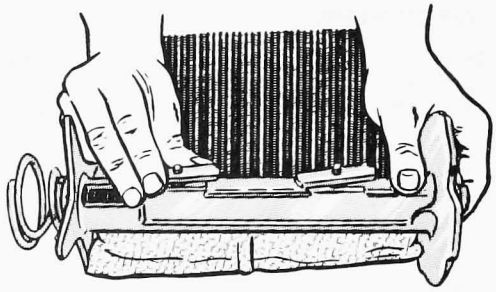
4. Install second gasket over studs and down against spacer retainer.



5. Insert ring studs in spool through oil channel.



6. Install wing nuts over studs and tighten until nuts are parallel with spool.



7. Place filter assembly on clean flat surface with wire mesh spacer on top and filter bag on bottom. Roll bag and spacer around spool so that spacer is between bag and studs.

FIG. 10 Assembling Full Flow Filter Bag and Spacer— Cummins Diesel

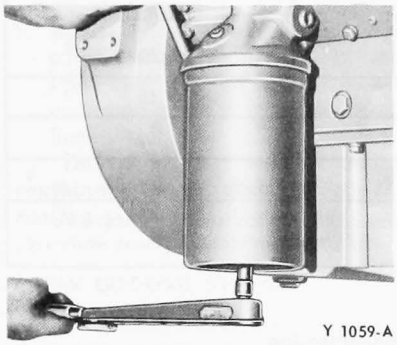

FIG. 11 Changing Paper Filter Element—Cummins Diesel

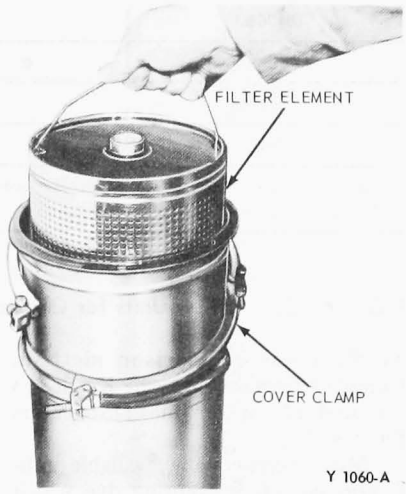

FIG. 12 By-Pass Filter and Element—Cummins Diesel

CUMMINS DIESEL ENGINES

MAINTENANCE

CHECK FAN HUB AND DRIVE PULLEY

Check the fan hub and drive pulley to be sure that they are securely mounted.

Tighten the fan capscrews. Check the drive pulley for looseness or wobble, and, if necessary, remove fan and hub and tighten the shaft nut. Tighten the bracket capscrews.

CHECK AIR INTAKE PIPING

Check air intake piping from air cleaner to intake manifold (Fig. 13). Check for loose clamps or connections, cracks, punctures, or tears in hose or tubing, collapsing hose, or other damage. Tighten clamps or replace parts as necessary to insure an airtight air intake system. Make sure that all air goes through the air cleaner.

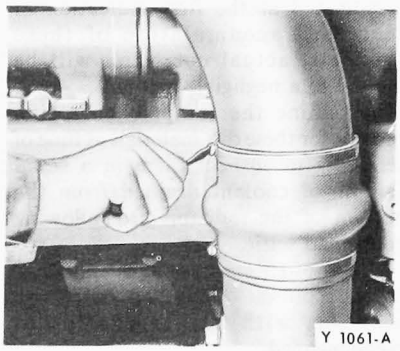

FIG. 13 Checking Air Inlet Piping

DRIVE BELT TENSION ADJUSTMENT—NH-SERIES DIESEL ENGINES

Fan Belts

Loosen the adjusting screw lock nut or the fan hub. Adjust the fan hub adjusting screw to obtain the specified fan belt tension (Specifications Section) and tighten the lock nut.

Water Pump Belts

1. Loosen the alternator adjusting bracket and the alternator to mounting bracket bolts. Loosen the water pump retainer mounting bolts.
2. Pivot the water pump assembly to obtain the specified drive belt tension (Specifications Section) and tighten the water pump retainer bolts to specifications.
3. Adjust the alternator to obtain the specified drive belt tension and tighten the adjusting bracket bolt and alternator to mounting bracket bolts.

DRIVE BELT TENSION ADJUSTMENT—NH-SERIES ENGINES— LN-SERIES TRUCKS

1. Loosen the water pump retainer bolts. Loosen the alternator to mounting bracket bolts and the adjusting bracket bolt. Loosen the adjusting lock nut on the cooling fan hub and back-off the adjusting screw.
2. Adjust the tension of the cooling fan belts to specification (Specifications Section) by means of the adjusting screw and tighten the adjusting lock nut. Pivot the water pump assembly counterclockwise until the specified tension on the pump belts is obtained and tighten the water pump retainer bolts.

CUMMINS DIESEL ENGINES—RECORD OIL PRESSURE

Start the engine and operate at 800 to 1000 rpm until the oil temperature gauge reads 140 degrees F. Reduce engine speed to idle and record the oil pressure. A comparison of pressure at idling speed with previous readings will give an indication of progressive wear of lubricating oil pump, bearings, shafts, etc. These readings are more accurate and reliable when taken immediately after an oil change.

TIGHTEN ENGINE MOUNTING BOLTS

Mounting bolts may occasionally work loose and cause the supports and brackets to wear rapidly. Tighten all mounting bolts or nuts and replace any

broken or lost bolts or capscrews. Refer to Cummins Shop Manual.

STEAM CLEAN ENGINE

There are many reasons why the exterior of the engine should be kept clean. Dirt from the outside will find its way into the fuel and lubricating oil filter cases and into the rocker housings when the covers are removed unless dirt is removed first.

Steam is the most satisfactory method of cleaning a dirty engine or piece of equipment. If steam is not available, use mineral spirits or some other solvent to wash down the engine.

All electrical components and wiring should be protected from the full force of the steam jet.

DRAINING AND FILLING COOLING SYSTEM—NH SERIES ENGINE

To prevent loss of anti-freeze when draining the radiator, attach a hose to the radiator drain cock and drain the coolant from the radiator into a clean container.

To drain the radiator, open the drain cock located at the bottom of the radiator. The cylinder block is drained by opening one drain plug located at the right rear of the block. Also, drain the oil cooler and heat exchanger (if so equipped).

To fill the cooling system, close the drain cocks, venting is automatic.

On downflow radiators, operate the engine and add more coolant, if necessary, to fill the radiator to the proper level. On trucks without a supply tank, fill the radiator one inch above the baffle (or core). On trucks equipped with a supply tank, fill the supply tank 2/3 full.

On L-Series, fill until the coolant is 1 inch from the top of the tank with engine cold. (Caution—Do not operate engine if coolant level is below the lower sight glass). After the initial fill, the coolant **level will drop approximately 1 quart when the engine has been operated about 20 minutes at 2000 rpm. This is due to the displacement of entrapped air.**

CHECK CONDITION OF COOLANT

Periodic tests of engine coolant should be made to insure the frequency of corrosion resistor servicing or concentration of chromate is adequate to control corrosion for the specific condition of operation.

When using plain water in a cooling system with a corrosion resistor (with chromate-type element) or when treating with chromate compounds the concentration of effective inhibitor dissolved in the coolant can be measured by the color comparison method. Cummins Coolant Checking Kit St-993 is available from Cummins Distributors for this check.

Ounces Per Gallon (Oz./Gal.)	Parts Per Million (PPM)	Grains/Gallons (Gr./Gal.)
0.16	850	50
0.32	1700	100
0.50	2550	150

If chromate compounds are used, add enough compound to bring concentration to proper level. Normal usage is one-half (1/2) ounce chromate for each one gallon coolant.

CY1211-B

FIG. 14 Comparison Units for Chromate Concentration

Most commercially available anti-freezes contain a coloring dye which renders the color comparison method ineffective. When colored anti-freezes are present in the coolant effective control of corrosion can be determined by inspecting the coolant for accumulation of reddish-brown or black finely granulated dirt. A small amount of corrosion produces significant quantities of these corrosion products; therefore, if corrosion resistor servicing is adjusted at the first indication of increased accumulation of these products, actual corrosion will be limited to a negligible amount.

Examine the sump of corrosion resistor for these dirt materials at time of servicing or inspect them in a small sample of coolant drained from the bottom of the radiator after allowing coolant to settle.

Use of chromate compound, added to the coolant without a corrosion resistor, with anti-freeze is not recommended.

PH Value Test

1. Separate tubes marked PH are furnished in the test kit. Select a tube and fill to mark with coolant to be checked.
2. Add eight drops of the PH Reagent to tube and mix thoroughly.
3. Insert the tube in the comparator hole marked PH.
4. Compare color of test sample with color standards on either side. Preferred range is 8.3 to 9.5.
5. Wash out test tubes after each test and keep reagent container caps in place.

Chromate Concentration Test

1. Draw sample of coolant and pour into tube marked CHROMATE.
2. Insert sample into comparator, hole marked CHROMATE.
3. Compare color of test sample with color standards on either side. Preferred range (Fig. 14) is 100 to 150 grains per gallon or 1700 to 2500 parts per million (ppm).
4. Wash test tubes thoroughly after each test.

Adjusting Coolant to Specifications

If the tests indicate that the coolant is outside specifications, make an adjustment immediately to prevent corrosion.

If the Cummins Corrosion Resistor is used, change the element or elements and run engine four to six hours; then, check coolant again. In extreme cases it may be necessary to change element a second time. However, the latter condition may be due to a larger coolant system than the corrosion resistor was designed to treat. Note reference on resistor label.

CORROSION RESISTOR ELEMENT REPLACEMENT

Check the coolant chromate concentration to determine if the corrosion resistor element should be changed.

Change the chromate element when the concentration drops below 1700 parts per million. To change the element, perform the following procedure.

1. Close the shut-off valves on the inlet and drain lines of the corrosion resistor assembly. Unscrew the drain plug at the bottom of the housing (Fig. 15).
2. Remove the cover retaining bolts. Remove the cover (with hose attached) and gasket. Discard the gasket. Remove the upper plate, element, lower plate and the spring from the housing. Discard the element.
3. Polish the surfaces of both plates. If less than one-half of the upper and lower surfaces of each plate can be exposed by polishing, replace the plate.
4. Install the spring and lower plate. Remove the transparent bag from the new resistor element, and install the element in the housing

5. Install the upper plate, gasket and cover. Install the drain plug, and open the shut-off valves in the corrosion resistor inlet and drain lines.

Do not add any radiator sealers containing water soluble oil to the cooling system as it will make the corrosion resistor plates inoperative.

CLEAN COOLING SYSTEM

The cooling system must be clean to do its work properly. Scale in the system slows down heat absorption from water jackets and heat rejection from the radiator. **Use clean water which will not clog any of the hundreds of small passages in the radiator or water passages in the block.**

Clean out radiator cores, heater cores, oil cooler, and block passages which have become clogged with scale and sediment by chemical cleaning, neutralizing and flushing.

Chemical Cleaning

The best way to insure an efficient cooling system is to prevent formation of rust and scale by using a Cummins Corrosion Resistor, but if they have collected, the system must be chemically cleaned. Use a good cooling system cleaner such as sodium bisulphate or oxalic acid followed by neutralizer and flushing.

Pressure Flushing

Flush the radiator and block when anti-freeze is added or removed, or before installing a Corrosion Resistor on a used engine.

When pressure flushing the radiator, open the upper and lower hose connections and screw the radiator cap on tight. Remove thermostats from housing and flush block with water. Use hose connections on both upper and lower connections to make the operation easier. Attach the flushing gun nozzle to the lower hose connection and let water run until the radiator is full. When full, apply air pressure **gradually** to avoid damage to the core. Shut off air and allow radiator to refill, then apply air pressure. Repeat until water coming from radiator is clean. **Do not backflush cooling systems that have a water shut-off valve in the heater system.**

Sediment and dirt settles into pockets in the block as well as the radiator core. Remove thermostats from housing and flush block with water. Partially restrict the lower opening until the block fills up. Apply air pressure and force water from the lower opening. Repeat the process until stream of water coming from block is clean.

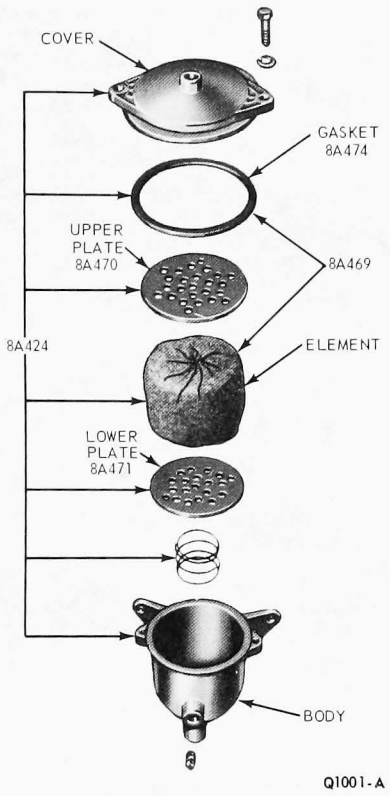

FIG. 15 Corrosion Resistor

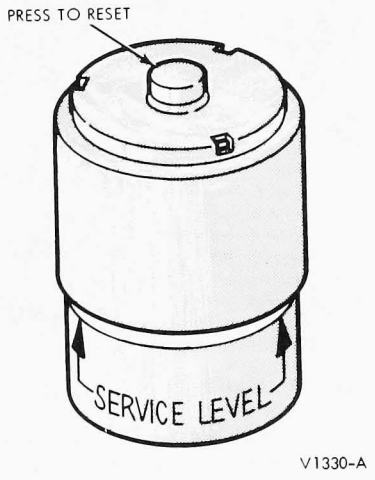

FIG. 16 Mechanical Restriction Indicator Gauge

CHECK INLET AIR RESTRICTION

The best method for determining dry-type air cleaner maintenance periods is through air restriction checks.

Check Air Inlet Restriction at Engine

1. On naturally aspirated engines attach a vacuum gauge or water manometer in the middle of the intake manifold or on the air intake piping. When located in the air intake piping, the adapter must be perpendicular to the air flow and not more than 6 inches from the air intake manifold connection.
2. On turbocharged or supercharged engines, attach the checking fixture on pipe diameter upstream from the supercharger or turbocharger in a straight section of tubing.
3. Idle the engine until normal operating temperature is reached.
4. Operate engine at rated speed full-load and take reading from vacuum gauge or manometer. Air restriction must not exceed 25 inches of water or 1.8 inches of mercury.
5. If air restriction exceeds 25 inches of water or 1.8 inches of mercury:

Clean or replace dry-type cleaner element.

Replace damaged air piping, rain shield or housing.

Remove excessive bends or other source of restriction in air piping.

Check Air Inlet Restriction at Cleaner

A mechanical restriction indicator is installed on the air cleaner. The gauge shows completely red in the indicator window when restriction reaches 25 inches of water (Fig. 16).

CHANGE CRANKCASE BREATHER

Dry-type crankcase breathers containing a chemically treated paper element are used on naturally aspirated engines. Install new element— **Do not attempt to clean. Do not use on engines with pressurized systems.**

CHECK AIR BOX DRAIN TUBES

During normal engine operation, water vapor from the air charge, as well as a slight amount of fuel and lubricating oil fumes, condense and settle on the bottom of the air box. This condensation is removed by the air box pressure through air box drain tubes mounted on the side of the cylinder block (Fig. 17).

The air box drain tubes must be open at all times. With the engine running, check for air discharge by placing your finger at the outlet end of the drain tube. If no air flow is felt, the drain tube is plugged and must be removed and cleaned. Also, remove the air box covers and wipe out the liquid accumulation on the bottom of the cylinder block air box. Then, blow out the drain passages with compressed air. Reinstall the air box covers and drain tubes. Tighten the air box cover bolts to 8-12 ft-lb torque.

FUEL PUMP ADJUSTMENTS

Only those fuel pump adjustments described herein should be performed in the truck. Make the adjustments in the order given.

In-chassis adjustments of the fuel pump are based on fuel manifold pressure and fuel supply vacuum. To determine these pressures follow the procedures in Group 25 of the 1973 Truck Shop Manual.

The following adjustment procedures refer to forward throttle screw and rear throttle screw. The forward throttle screw is closer to the drive end of the fuel pump (Fig. 18).

Before Making Adjustments

1. Operate the engine until the oil temperature reaches 140 degrees to 160 degress F. Make all fuel pump or injector settings on a hot engine.
2. Install a vacuum gauge Cummins (ST-434) in the fuel supply line (Fig. 19). Check the suction restriction of the fuel supply line. If the vacuum reading exceeds 8 inches of mercury, determine the cause and correct.
3. Adjust valve and injector lash to specifications.
4. Check high-idle or maximum governed speed.

Rear Throttle screw Adjustment

1. Connect a manifold pressure gauge Cummins (ST-435) at the manifold pressure gauge connection. Check the fuel manifold pressure at rated speed and full load.
2. Turn the rear throttle screw out until the highest fuel manifold pressure reading is obtained.
3. Turn the rear throttle screw in to reduce the fuel manifold pressure 5 psi.

Do not increase the rear throttle adjustment more than 5 psi or the engine speed at which peak torque occurs will change. Throttle restriction over 5 psi allows unauthorized adjustment to raise fuel manifold pressure, thereby overfueling the engine.

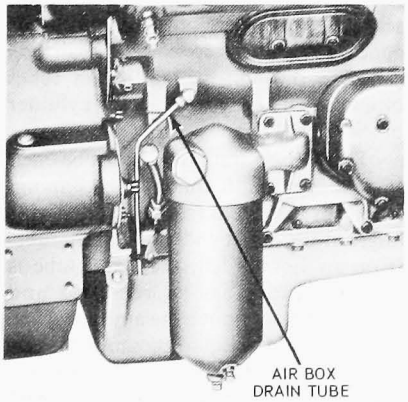

FIG. 17 Air Box Drain Tube

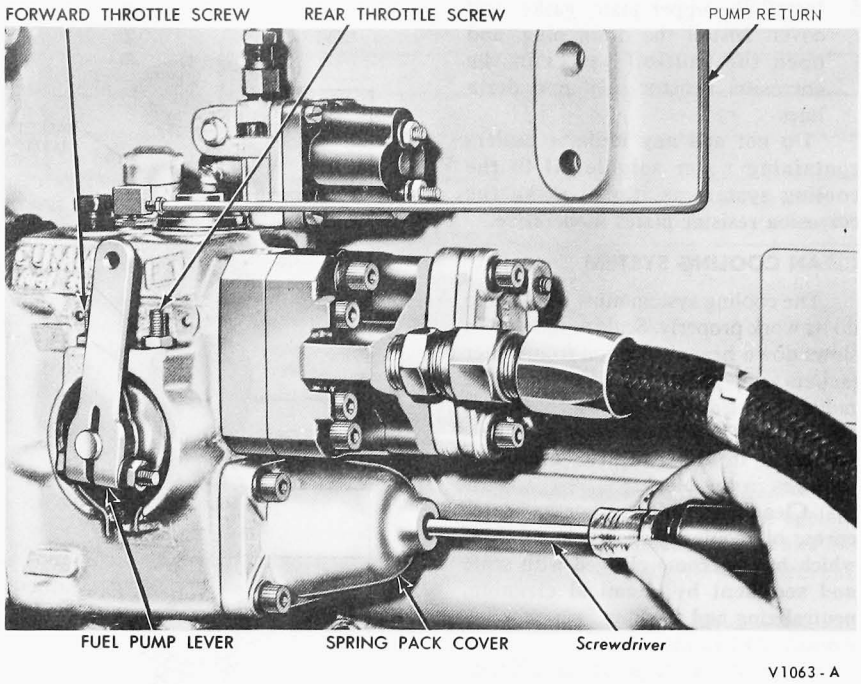

FIG. 18 Fuel Pump Adjustments

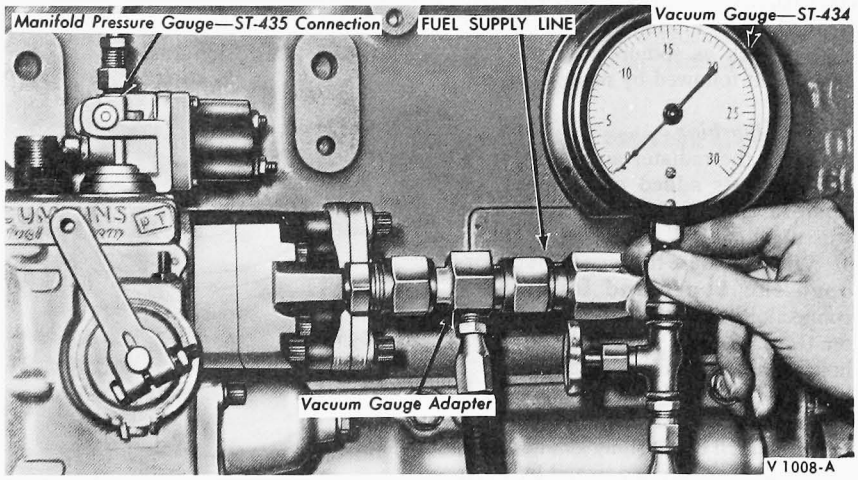

FIG. 19 Fuel Pump Gauge Connections

Forward Throttle Screw or Throttle Leakage Adjustment

1. With the engine operating at idle speed, turn in the forward throttle screw until the engine gains speed. Back the screw out two full turns.
2. Stop the engine and remove the spring pack cover plug and adjust the idle governor screw (Fig. 18) to idle the engine at specified rpm (see specifications).
3. Operate the engine until it is purged of the air let in during Step 1.
4. Check the idle speed.
5. Check deceleration; if it is too slow, the throttle leakage is excessive. If the engine falters or dies when idle speed is reached, the throttle leakage is too low. Adjust the screw to obtain permissible deceleration time.
6. Any change in the desired idle speed is made with the governor idle screw. Follow the sequence under Idle Speed Adjustments.

Idle Speed Adjustments

1. With the engine stopped, remove the pipe plug from the spring pack cover.
2. The idle adjustment screw is held in position with

screw in to increase, or out to decrease the speed (Fig. 18).

3. Replace the pipe plug. With the engine running, air which collected in the spring pack housing will cause a rough idle temporarily. This will stabilize when the housing fills with fuel.

CLEAN FUEL PUMP SCREEN AND MAGNET

To clean filter screen:

1. Loosen and remove cap at top of fuel pump. Remove spring. Lift out filter screen assembly (Fig. 20).
2. Remove top screen retainer from filter screen assembly.

Some filter screens do not contain a magnet. If not, a magnet can be obtained from any Cummins distributor. Magnetic action will remove any ferrous metal particles that may enter fuel system.

3. Clean screen and magnet in cleaning solvent and dry with compressed air.
4. Replace screen retainer and install filter screen assembly in fuel pump with hole down. Replace spring on top of filter screen assembly.
5. Replace cap, tighten to 20-25 ft-lbs.

CLEAN INJECTORS

Refer to the applicable Cummins Diesel service manual for cleaning and inspection of the injectors.

ADJUST INJECTOR AND VALVE LASH

Refer to the applicable Cummins Diesel Service Manual for injector and valve lash adjustments.

CROSSHEAD ADJUSTMENTS

Refer to the applicable Cummins Diesel Service Manual for the crosshead adjustment procedure.

INJECTOR PLUNGER ADJUSTMENT

Refer to the applicable Cummins Diesel Serivce Manual for the injector plunger adjustment procedure.

FUEL FILTER ELEMENT REPLACEMENT

The fuel filter (Fig. 21) has a disposable-type element. Replace it at the specified interval, even though it may appear serviceable. Unscrew the combination filter case and element and discard it. Install the new filter case and element assembly and tighten it by hand until the O-ring seal touches the filter head. Then tighten it an additional 1/4 to 1/2 turn by hand. If the replacement filter doesn't have an integral O-ring seal, use a new O-ring for installation.

FIG. 20 Removing Fuel Pump Filter Screen

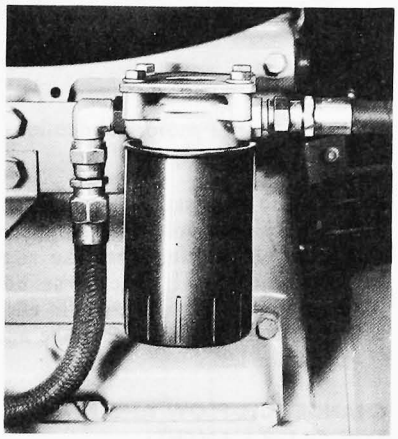

FIG. 21 Typical Engine Mounted Fuel Filter—NH-Series Engines

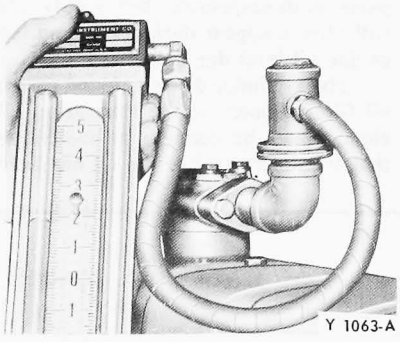

FIG. 22 Checking Blow-By Under Load

CHECK ENGINE BLOW-BY

Engine blow-by, or escape of combustion gases past pistons and liners, is usually caused by worn or stuck piston rings, worn cylinders liners, or worn pistons.

Blow-by can be detected by running the engine and observing the gas escape from the lubricating oil filler hole with cap or breather open or removed. There is always some vapor or gas escape at this point due to heated oil and piston movement, but distinct puffs indicate blow-by. Experience and comparison with other units operating at the same speed are needed to make a conclusion as to the extent of blow-by. Normally, excessive blow-by is accompanied by oil consumption.

Cummins Distributors are equipped to check engines for blow-by under loaded conditions, with special tools, to determine if blow-by is excessive (Fig. 22).

CHECK THERMOSTAT

Most Cummins Engines are equipped with either high (170/185 degrees F) or low (160/175 degrees F) thermostats, depending on engine application.

The lower value indicates where thermostat starts to open and the higher value where it is fully open. Check stamping on thermostat; install same range new thermostat as that removed.

The opening and closing of thermostats can be checked against a thermometer while immersed in water as the water is brought up to temperature by heating.

TIGHTEN MANIFOLD NUTS OR CAPSCREWS

Check exhaust, intake and water manifolds mounting hardware for tightness; correct deficiencies as required.

Refer to the applicable Cummins Service Manual.

CLEAN STARTER MOTOR AND ALTERNATOR

Dust and dirt, if allowed to accumulate in the alternator and cranking motor, will cause excessive wear of bearings, brushes and commutator.

Remove the cover band and/or rubber shield and blow out the dust and dirt with compressed air.

DETROIT DIESEL ENGINES

LUBRICATION

LUBRICATE ACCELERATOR LINKAGE

Lubricate the friction points of the accelerator linkage with the specified lubricant (Part 50-03) at the recommended mileage interval.

LUBRICATE STARTER MOTOR

Some starting motors do not require lubrication except during overhaul. However, motors (Fig. 23) which are provided with lubrication fittings (grease cups, hinge cap oilers, or oil tubes sealed with pipe plugs) should be lubricated at the specified interval.

Add 8 to 10 drops of oil, of the same grade as used in the engine, to hinge cap oilers; if sealed tubes are provided, remove the pipe plugs, add oil and reseal the tubes. Grease cups should be turned down one turn. Refill the grease cups, if necessary.

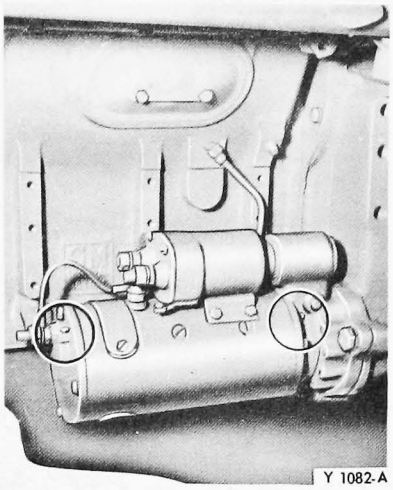

FIG. 23 Starter Motor Lubrication Points—Typical

ENGINE OIL LEVEL

DETROIT DIESEL

Do not operate the engine with the oil level below the LOW mark.

Do not add oil to any engine to raise the oil level above the mark indicating FULL.

CHANGE ENGINE OIL

1. Remove the oil pan drain plug, drain oil into a container, then replace the plug.

Install new filter elements each time the oil is changed.

2. Fill the crankcase with the specified engine oil shown in the owner's handbook.

Overfilling the crankcase may contribute to abnormal oil consumption, high oil temperatures, and may also result in oil leaking past the rear crankcase oil seal which was not intended to operate submerged in oil.

3. Operate the engine at fast idle and check for leaks.

CHANGE FULL-FLOW AND BY-PASS TYPE FILTER ELEMENTS

With the use of detergent lubricating oils. The color of the lubricant has lost value as an indicator of oil cleanliness or proper filter action. Due to the exceptional ability of the detergent compounds to hold minute carbon particles in suspension, **heavy duty oils will always appear dark-colored on the engine oil level dipstick.**

Heavy sludge deposits found on the oil filter element at the time of an oil change must be taken as an indication that the detergency of the oil has been exhausted. When this occurs, the oil drain interval should be decreased. The removal of abrasive dust, metal particles, and carbon must be ensured by replacement of the oil filter element at the time the engine oil is changed.

Selection of a reliable oil supplier, strict observation of his oil change period recommendations, and proper filter maintenance will ensure trouble-free lubrication and longer engine life.

The oil filter elements should be changed every time the engine oil is changed.

The element in either the full-flow filter or by-pass filter assembly (Figs. 24 and 25) may be replaced as follows:

1. Remove the drain plug from the shell or base and drain the oil from the filter.
2. Back out the center stud and withdraw the shell, element, and stud as an assembly. Then, remove and discard the filter element.
3. Clean out the old oil from the filter shell and adapter or base.
4. Install a new shell gasket in the filter adapter or base.
5. Install a new filter element over the center stud within the shell. Then, place the shell, element, and stud assembly in position on the filter adapter or base and tighten the center stud carefully to avoid damage to the gasket.
6. Install the drain plug.
7. Start and run the engine for a short period and check for oil leaks. After any oil leaks have been corrected and the engine has been stopped long enough for the oil from various parts of the engine to drain back to the crankcase, bring the oil to the proper level on the dipstick.

DETROIT DIESEL ENGINES

MAINTENANCE

The following maintenance operations are to be performed **only by Detroit Diesel Service Dealers using the procedures in the applicable Detroit Diesel Service Manual:**

Check Fan Hub and Drive Pulley.
Check Thermostats.
Check Engine Blow-By.
Clean Injector Inlet Screen.
Clean Injectors.
Clean Blower Screen and Check Seals.
Clean Crankcase Breather.
Adjust Injectors and Valve Lash.
Tighten Mounting Bolts.
Check Engine Emergency Shut-Down Cable.

CHECK COOLING SYSTEM HOSES

Check the cooling system hoses for deterioration or damage and replace, if necessary (Fig. 26). Check all of the hose clamps to make sure they are tight and properly seated on the hoses.

REPLACE FUEL FILTER AND STRAINER ELEMENTS

1. With the engine stopped, place a container under the strainer or filter and open the drain cock (Figs. 27 and 28). Loosen the cover bolt just

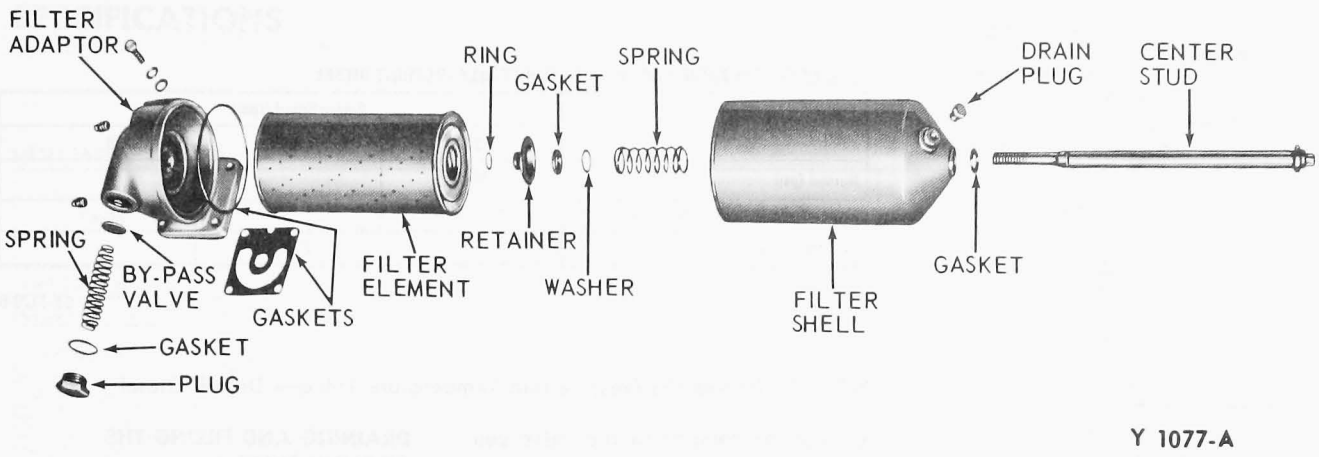

FIG. 24 Full-Flow Filter—Cummins Diesel

enough to allow the fuel to drain out freely. Then, close the drain cock.

The wiring harness, starting motor, or other electrical equipment must be shielded during the filter change, since fuel oil can permanently damage the electrical insulation.

2. While supporting the shell, unscrew the cover bolt and remove the shell and the element.
3. Remove and discard the element and the shell gasket.
4. Wash the shell thoroughly with fuel oil and dry it with compressed air.
5. Examine the element seat and the retaining ring to make sure they have not slipped out of place. Check the spring by pressing on the element seat. When released, the seat must return against the retaining ring.

The element seat, spring, washer and seal cannot be removed from the strainer shell. If necessary, the shell assembly must be replaced. However, the components of the filter shell are serviced.

6. Place a new element over the stud and down against the seat. Make sure the drain cock is closed; then, fill the shell about two-thirds full with clean fuel oil.

Thoroughly soak the density-type STRAINER element in clean fuel oil before installing it. This will expel any air entrapped in the element and is conducive to a faster initial start.

7. Install a new gasket in the recess of the shell.
8. Place the shell and element in position under the cover. Then, thread the cover bolt into the stud.

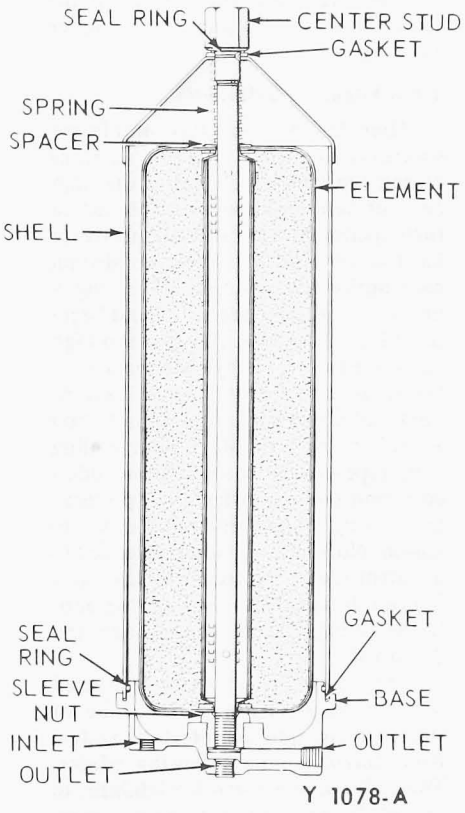

FIG. 25 By-Pass Type Oil Filter—Cummins Diesel

On a W-Series truck with Detroit Diesel 8V-71 Engine the drain cock must be pointing to the rear of the engine to prevent interference with the cab retaining arm.

9. With the shell and gasket properly positioned, tighten the cover bolt just enough to prevent leakage.

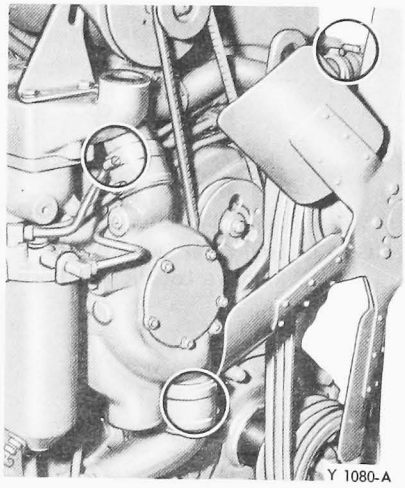

FIG. 26 Cooling System Hoses Check Points

10. Remove the filler plug in the cover and complete filling of the shell with fuel. Primer J 5956 may be used to prime the entire fuel system.
11. Start the engine and check the fuel system for leaks.

CLEAN COOLING SYSTEM

Drain and flush the cooling system to remove the anti-freeze solution in the spring and the rust inhibitor in the fall, thus preparing the cooling system for the next olution. If necessary, use a cooling system cleaner and reverse flush. Refill the cooling system with clean soft water and add rust inhibitor or anti-freeze. Start the engine and check for leaks. **CAUTION—Do not backflush cooling systems that have a water shut-off valve in the heater**

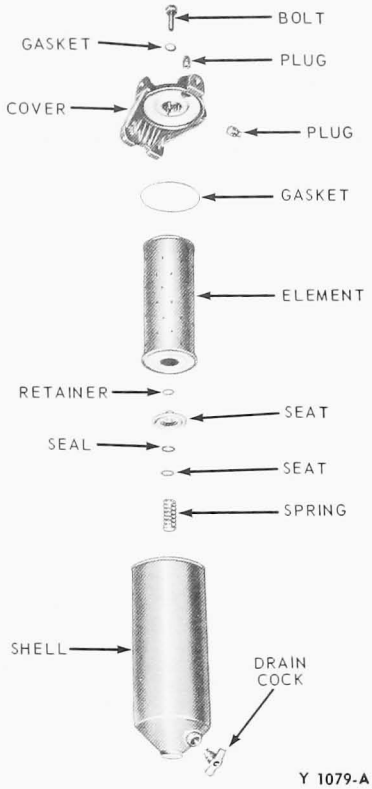

FIG. 27 Fuel Filter Details and Relative Location of Parts.

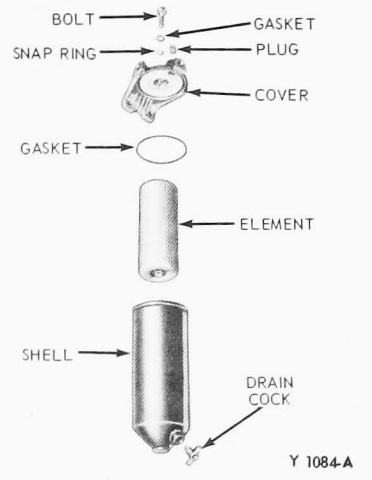

FIG. 28 Fuel Strainer Details and Relative Location of Parts

ENGINE OIL PRESSURE AND TEMPERATURE TABLE–DETROIT DIESEL

	Engine Speed (rpm)		
	1200	1800	2100
Normal (psi)	40-55	50-70	
Minimum for Safe Operation (psi)	25	28	30
Oil Temperature –°F	20-235		

CY 1170-B

FIG. 29 Engine Oil Pressure and Temperature Table— Detroit Diesel

system, or damage to the valve can result.

WATER FILTER AND CONDITIONER

For maintenance of the engine coolant and water filter, refer to the Detroit Diesel Engine Maintenance Manual.

ANTI-FREEZE SOLUTIONS

High boiling point type anti-freeze solutions are used in diesel engines during the winter because of the high coolant temperature encountered in their operation. Alcohol base anti-freeze has too low a boiling point. An alcohol base anti-freeze solution protecting a unit to minus 20 degrees F would begin to boil at 180 degrees F, whereas a high boiling point type ethylene glycol anti-freeze solution protecting a unit to minus 20 degrees F would begin to boil at 223 degrees F. Most high boiling point type anti-freeze solutions include a corrosion inhibitor which will protect the cooling system through the winter season. No additives should be added to a system that is protected by this anti-freeze solution. In the spring, the anti-freeze solution should be drained and discarded.

The corrosion inhibitor in a used anti-freeze solution will not be of sufficient strength to protect the system from corrosion the following winter. The addition of a corrosion inhibitor to an anti-freeze solution to permit reuse could cause a reaction within the solution. A precipitation could result and clog the cooling passages, necessitating extensive engine and radiator cleaning.

DRAINING AND FILLING THE COOLING SYSTEM

To drain the radiator, open the drain petcock at the bottom of the radiator and drain the coolant into a container to prevent loss of anti-freeze. The radiator will drain faster if the filler cap is removed.

To drain the cylinder block, open the two drain petcocks on each side of the engine block and on the bottom of the oil cooler.

To fill the cooling system, close the drain petcocks and pour the coolant into the radiator. Operate the engine until operating temperature is obtained and check the coolant level.

DETROIT DIESEL ENGINES—RECORD OIL PRESSURE

Check and record the engine oil pressure at maximum no-load rpm. The table lists the specified engine oil pressures and temperatures. These readings are more accurate and reliable when taken immediately after an oil change (Fig. 29).

SPECIFICATIONS

CHECK AND ADJUST IGNITION TIMING—INITIAL TIMING, MECHANICAL AND VACUUM ADVANCE AND VACUUM RETARD

TIMING MARK LOCATIONS

The timing marks and their locations are illustrated in Figs. 1, 2 and 3.

The timing mark on the 240 engine in the Econoline and the 240 and 300 engines in P-Series trucks is a machined groove on the flywheel (Standard Transmission) or a stamped line on the flexplate (Automatic Transmission). It is viewed through an opening in the engine rear cover plate (Fig. 3) on the lower left side of the engine. A rubber plug covers the opening to prevent the entrance of dust and dirt. Steel stamped degree marks ranging from 0 degree or top dead center (TDC) to 14 degrees, before top dead center (BTDC) are located at the edge of the opening.

When checking the timing, the timing mark on the flywheel (or flexplate) should be in line with the specified degree mark on the engine rear cover plate opening when the timing light flashes.

INITIAL IGNITION TIMING

Because of the high engine idle speeds required on exhaust emission control engines, precautions must be taken when setting the initial ignition timing to be sure that the distributor is not partially advanced. To be sure that no distributor advance is taking place, idle speed should be reduced to 600 rpm **after the vacuum hoses have been disconnected from the diaphragm unit and plugged.** Reset the idle to the specified rpm after adjusting the initial timing. Initial ignition timing and idle specifications for 1973 Trucks are given in the 1973 Truck Specifications Book.

1. Clean and mark the timing marks.
2. Disconnect the vacuum line (singlediaphragm distributors) or vacuum lines (dualdiaphragm distributor), and plug the disconnected vacuum line(s) (Fig. 4).
3. Connect a timing light to the No. 1 cylinder spark plug wire. Connect an engine speed tachometer.
4. Start the engine and reduce the engine idle speed to 600 rpm to be sure that the centrifugal advance is not operating. Adjust the initial ignition timing to specifications by rotating the distributor in the proper direction.
5. Check the centrifugal advance for proper operation. Start the engine and accelerate it to approximately 2000 rpm. If the ignition timing advances, the centrifugal advance mechanism is functioning properly.

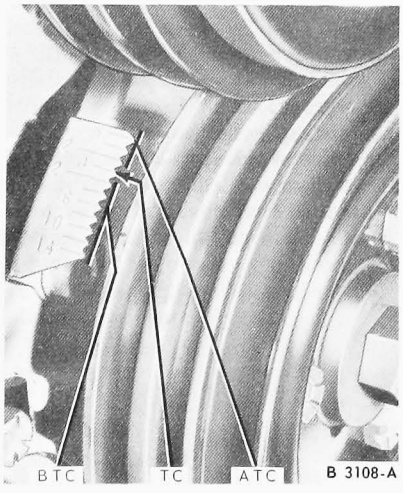

FIG. 1 Typical Engine Timing Marks—Pointer Mounted

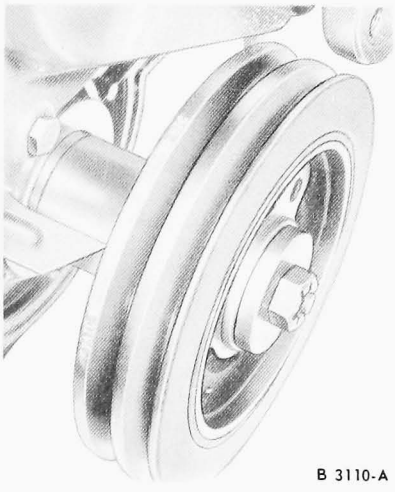

FIG. 2 Typical Engine Timing Marks—Pulley Mounted

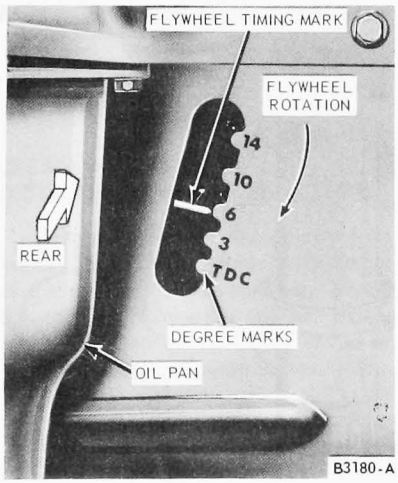

FIG. 3 Engine Timing Marks—240 Engine—Econoline and 240, and 300 Engines—P-Series Trucks

Note the engine speed when the advance begins and the amount of advance. Stop the engine.

6. Unplug the carburetor source vacuum line and connect it to the distributor vacuum advance unit (outer diaphragm on dual diaphragm distributors). Start the engine and accelerate it to approximately 2000 rpm. Note the engine speed when the advance begins and the amount of advance. Advance of the ignition timing should begin sooner and advance farther than when checking the centrifugal advance alone. Stop the engine.
7. Check the vacuum retard operation on dual diaphragm distributors. Connect the intake manifold vacuum line to the inner (retard) diaphragm side of the vacuum advance. Reset the carburetor to normal idle speed. The initial timing should retard to approximately TDC, if the initial ignition timing is correct. On some engines it will go as low a 4 degrees ATDC (degrees after top dead center).

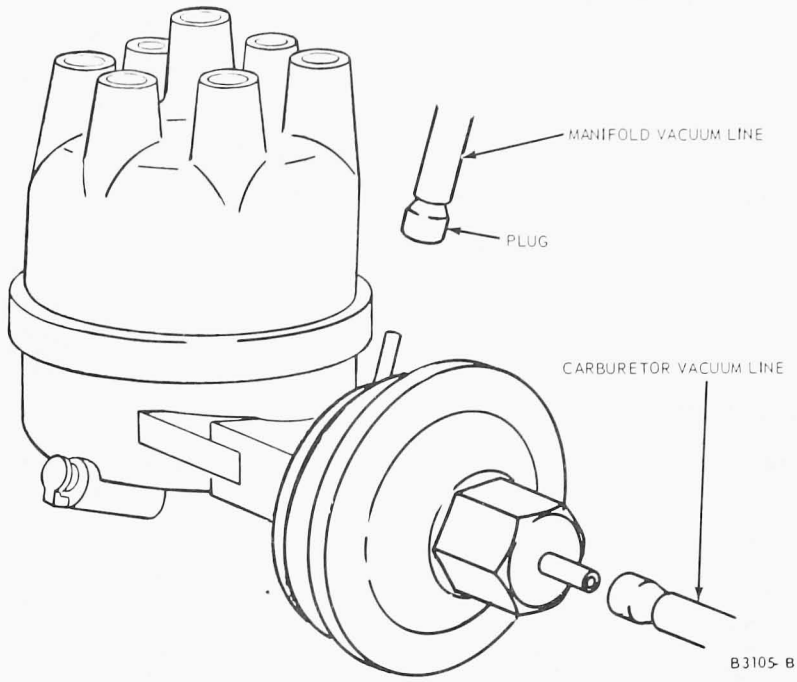

FIG. 4 Adjusting Dual Diaphragm Distributor

8. If the vacuum advance or vacuum retard (dual diaphragm distributors) is not functioning properly (refer to steps 6 and 7 above), remove the distributor and check it on a distributor tester. Replace the dual diaphragm unit if the retard portion is out of calibration, the advance portion cannot be calibrated to specifications, or either of the diaphragms are leaking.

LUBRICATION

LUBRICATE DISTRIBUTOR BUSHING (OIL CUP)

Squirt a few drops of SAE 10W engine oil into the distributor oil cup, if so equipped.

MAINTENANCE

INSPECT SECONDARY IGNITION WIRING

Inspect the secondary (high-tension) wiring for cracked insulation or indications of heat damage to the outer cover. Be sure that the spark plug wires are fully seated on the spark plugs and that the connections to the coil and distributor are bottomed in the receptacles provided.

REPLACE SPARK PLUGS

Removal

1. Remove the wire from each spark plug by grasping, twisting and then pulling the moulded cap of the wire by hand only. **Do not pull on the wire because the wire connection inside the cap may become separated or the weatherseal may be damaged.**
2. Clean the area around each spark plug port with compressed air, then remove the spark plugs.

Adjustment

Set the spark plug gap to specifications by bending the ground electrode (Fig. 5). **Never bend the center electrode.**

Installation

1. Install the spark plugs and torque each plug to 15-20 ft-lbs.
2. Connect the spark plug wires. Push all weather seals into position.

CHECK DISTRIBUTOR POINTS AND ADJUST DWELL

Use a dwell meter to check the contact dwell. It is not advisable to use a feeler gauge to adjust or to check the gap of used breaker points because the roughness of the points makes an accurate gap reading or setting impossible. Sand or file the breaker points and check and adjust the alignment. Check the spring tension. Check the contact dwell following the instructions of the dwell meter manufacturer.

BREAKER POINT ALIGNMENT

The pivoted-type breaker points used in Motorcraft distributors should be accurately aligned and strike squarely to assure normal breaker point life.

1. Turn the distributor cam so that the breaker points are closed and check the alignment of the points.

FIG. 5 Checking Spark Plug Gap

2. Using the tool shown in Fig. 6 and **using very light pressure,** align the breaker points to make full face contact by bending the stationary breaker point bracket (Fig. 6). **Do not bend the breaker arm.**
3. After the breaker points have been properly aligned, adjust the breaker point gap or dwell.

BREAKER POINT SPRING TENSION

To check the spring tension, place the hooked end of the spring tension gauge over the movable breaker point, then pull the gauge at a right angle (90 degrees) to the movable arm until the breaker points just start to open (Fig. 7). If the tension is not within specifications, adjust the spring tension.

To adjust the spring tension (Fig. 8):

1. Disconnect the primary and condenser leads at the breaker point primary terminal.
2. Loosen the nut holding the spring in position. **Move the spring toward the breaker arm pivot to decrease tension and in the opposite direction to increase tension.**
3. Tighten the locknut, then check spring tension. Repeat the adjustment until the specified spring tension is obtained.
4. Install the primary and condenser leads with the lockwasher and tighten the nut securely.

CHECK VACUUM ADVANCE/ RETARD CUT-IN SPEED

ALL TRUCKS BELOW 6000 G.V.W.

The complete test procedures covering the advance/retard cut-in speeds are covered in Group 23 of the 1973 Truck Shop Manual.

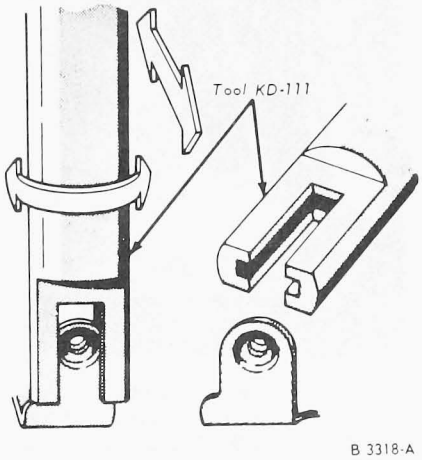

FIG. 6 Using Alignment Tool

CHECK OPERATION OF THERMAL SWITCH (TRS SPARK CONTROL SYSTEM)

ALL TRUCKS BELOW 6000 G.V.W.

Test procedures covering the thermal switch are in Volume VI of this manual.

CHECK SPARK CONTROL SYSTEM ADVANCE AND RETARD VACUUM (TRS SPARK CONTROL SYSTEM)

ALL TRUCKS BELOW 6000 G.V.W.

Using a tee fitting, install a vacuum gauge to the distributor diaphragm fitting. With the engine running, a minimum of 6 inches of **steady** vacuum should be obtained. A reading of 12 inches of vacuum is preferred. A low vacuum reading or a fluctuating vacuum indicates a restriction in the system. On vehicles equipped with a dual diaphragm distributor, take a reading at both the advance and retard diaphragms. To adjust the distributor diaphragm, refer to Group 23 of the 1973 Truck Shop Manual.

CHECK AND ADJUST DISTRIBUTOR SPARK ADVANCE

Remove distributor, install on test stand and adjust spark advance to the specifications in the 1973 Truck Specifications Book.

REPLACE SPARK DELAY VALVE

Refer to Volume VI of this manual, for spark delay replacement procedures.

CLEAN AND INSPECT DISTRIBUTOR CAP AND ROTOR

Remove the distributor cap and inspect for cracks. Also check the inside of the cap for carbon build-up. Check the contact points for erosion. Also, remove the rotor and check for cracks or a bent or corroded contact arm.

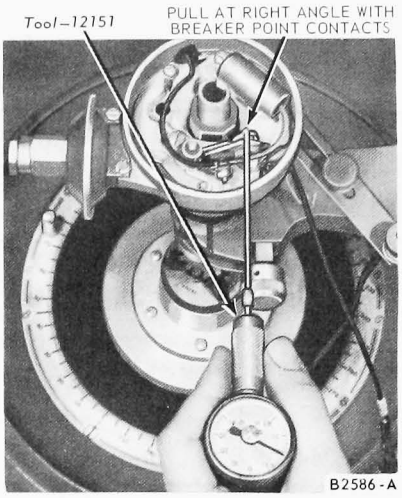

FIG. 7 Checking Breaker Point Spring Tension

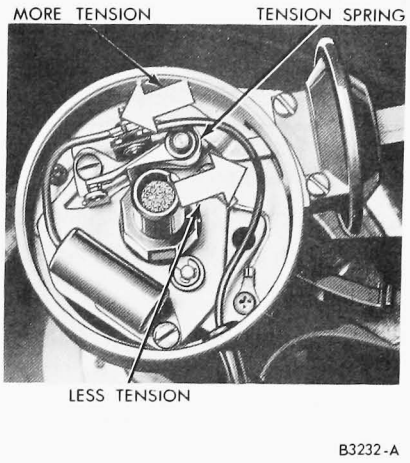

FIG. 8 Adjusting Spring Tension—Pivot-Type Points

SPECIFICATIONS

Refer to the Truck Specifications Book for all ignition system specifications.

PART 50-24 Fuel Systems—Gasoline

COMPONENT INDEX	Page	COMPONENT INDEX	Page

Choke Plate Pulldown and Fast Idle Cam Clearance	24-08		

PRE-DELIVERY

CHECK OIL BATH AIR CLEANER OIL LEVEL

Remove the reservoir from the air cleaner body. Fill the reservoir to the oil level mark if necessary with the specified motor oil. **Do not overfill the reservoir.**

ACCELERATOR PEDAL OPERATION

Check for full return, and sufficient pedal height to open throttle fully. (Remove air cleaner, hold choke plate open depress accelerator pedal fully and observe position of throttle plate. Plate should be in vertical position.) Check for binding or looseness, and adjust if necessary.

CHECK THROTTLE LINKAGE AND WIDE OPEN THROTTLE POSITION

Inspect the throttle linkage for proper installation. Remove the air cleaner, and with the accelerator fully depressed, observe the position of the carburetor throttle plate(s). They should be vertical (wide open position).

Check accelerator for sticking or binding and for full return and sufficient height to fully open throttle.

AUTOMATIC CHOKE OPERATION

Check the choke shaft for wear and excessive looseness or binding. Inspect the choke plate for nicked edges and for ease of operation and free it if necessary. Remove the choke thermostatic spring housing and make sure all carbon and foreign material has been removed from the automatic choke housing. Check the operation of the choke piston in the choke housing to make certain it has free movement.

CHECK AND ADJUST ENGINE IDLE SPEED

Refer to the Maintenance Section of this Part for the engine idle adjustment procedures.

INSPECT FUEL LINES AND FILTER FOR LEAKS

With the engine stopped, examine the fuel line connections for wetness or washed or stained areas that might indicate a fuel leak. Start the engine and observe all the connections for fuel seepage. Tighten or replace fuel lines as necessary.

CHECK FUEL TANK MOUNTING

Inspect the fuel tank mounting brackets and straps to be sure the fuel tanks are securely attached to the vehicle. Inspect the fuel line(s) at the tank(s) to be sure they do not leak. On Bronco, Econoline and F-100 4 x 2 and 4 x 4, be sure the sealed gas cap is not leaking. Make corrections as required.

LUBRICATION

CHECK OIL BATH AIR CLEANER OIL LEVEL

Remove the reservoir from the air cleaner body. Fill the reservoir to the oil level mark with the specified motor oil. **Do not overfill the reservoir. Inspect the gasket or seal between the reservoir and the air cleaner body. Replace the gasket or seal if damaged.**

CLEAN OIL BATH AIR CLEANER AND REFILL RESERVOIR

1. Remove the wing nut attaching the air cleaner to the carburetor and remove the air cleaner.
2. Remove the cover and drain the oil from the reservoir. Wash all the air cleaner parts in a suitable cleaning solvent. Dry them with compressed air.
3. Inspect the gasket between the oil reservoir chamber and cleaner body and replace it if necessary.
4. Saturate the filter element with engine oil.
5. Fill the oil reservoir to the full mark with the recommended engine oil.
6. Install the air cleaner on the carburetor.

MAINTENANCE

CLEAN CHOKE EXTERNAL LINKAGE

Examine the choke external linkage for free operation. If the linkage appears to be sticking, or is dirty, clean the linkage using a brush and common mineral-spirits type cleaning fluid.

AIR CLEANER THERMOSTATIC VALVE

Check operation. During warm-up period: when heated air entering air intake duct is less than 75 degrees F., valve plate should be in the up (heat-on) position; when temperature of heated air entering air intake duct reaches 105 degrees F., valve plate should be in the down (heat-off) position.

REPLACE CARBURETOR AIR CLEANER FILTER

1. Remove the wing nut attaching the air cleaner assembly to the carburetor. Disconnect the crankcase ventilation system hose at the air cleaner and remove the assembly.
2. Install a new air cleaner mounting gasket on the carburetor, if necessary.
3. Install the air cleaner body on the carburetor so that the word **Front faces the front.**
4. Place the air cleaner filter element in the air cleaner body.
5. Install the cover and tighten the wing nut.
6. Connect the crankcase vent hose to the air cleaner.

FUEL FILTER REPLACEMENT

DISPOSABLE FILTER

1. Unscrew the filter housing from the fuel pump, and remove the filter element and gasket. Discard the element and gasket. Clean the filter housing in cleaning solvent.
2. Place a new filter element over the spout in the fuel pump valve housing cover. **Be sure to use the proper type element for the installation.** Coat a new gasket with light engine oil and position the gasket on the filter housing (Figs. 1 and 2). Thread the filter housing onto the fuel pump. Hand tighten the filter housing until the gasket contacts the pump, and then advance it 1/8 turn.
3. Start the engine and check for leaks.

IN-LINE FUEL FILTER

The in-line fuel filter used on all engines is of one piece construction and cannot be cleaned. Replace the filter if it becomes clogged or restricted.

1. Remove the air cleaner.
2. Loosen the retaining clamp securing the fuel inlet hose to the fuel filter.
3. Unscrew the fuel filter from the carburetor. Disconnect the fuel filter from the hose and discard the retaining clamp.
4. Install a new clamp on the inlet hose and connect the hose to the filter. Thread filter into the carburetor inlet port. Tighten the filter.
5. Position the fuel line hose clamp and crimp or tighten the clamp securely.
6. Start the engine and check for fuel leaks.

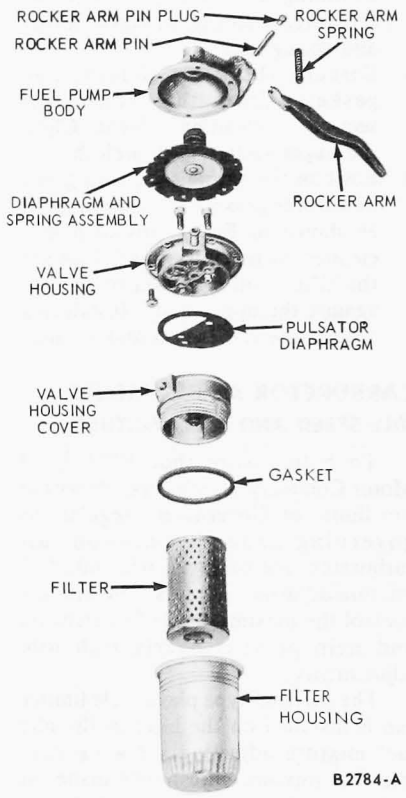

FIG. 1 Carter Fuel Pump Assembly—300 H.D., 330, 361 and 391 CID Engines

7. Install the air cleaner.

IN-LINE FUEL FILTER—500-800 SERIES—WITH ELECTRIC FUEL PUMP

1. Unscrew the lower section from the upper section and remove the filter

element and gasket (Fig. 3). Discard the element and gasket.
2. Clean the lower section in cleaning solvent. Clean the upper section with a cloth.
3. Coat a new gasket with light engine oil and position the gasket on the lower section.
4. Place a new filter element in the lower section.
5. Thread the lower section onto the upper section until the gasket contacts the upper section. Turn the lower section an additional 1/8 turn.

IN-LINE FUEL FILTER—850-900 SERIES—WITH ELECTRIC FUEL PUMP

1. Remove the drain plug from the filter bowl, and drain the fuel from the bowl into a suitable container (Fig. 4).
2. Remove the center bolt and washer, then remove the filter bowl and mounting gasket (Fig. 5). Remove the filter element, gaskets, spring and spring seat.
3. Discard the filter element and gaskets. Clean the filter lower section in cleaning solvent. Clean the upper section with a cloth.
4. Position the spring seat, spring and new lower gaskets in the filter bowl as shown in Fig. 5. Install a new element in the filter bowl. Position the filter and new upper gaskets against the upper body. Install and tighten the center bolt and washer.

CARBURETOR ADJUSTMENTS

IDLE SPEED AND FUEL MIXTURE

To help assure that 1973 Ford Motor Company vehicles operate within the limits of Government regulations governing exhaust emission, all carburetors are equipped with idle fuel mixture adjusting limiters. The limiters control the maximum idle fuel richness and help prevent overly rich idle adjustments.

The external-type plastic idle limiter cap is installed on the head of the idle fuel mixture adjusting screw(s). Any idle fuel mixture adjustment made on carburetors having this type of limiter must be within the range of the idle adjusting limiter. **Under no circumstances are the idle adjusting limiters or the limiter stops on the carburetor to be mutilated or deformed to render the limiter inoperative.** On a Motorcraft Model 2100-D 2-V carburetor; the power valve cover must be installed with the limiter stops on the cover in position to provide a positive stop for the tabs on the idle adjusting limiters (Fig. 6).

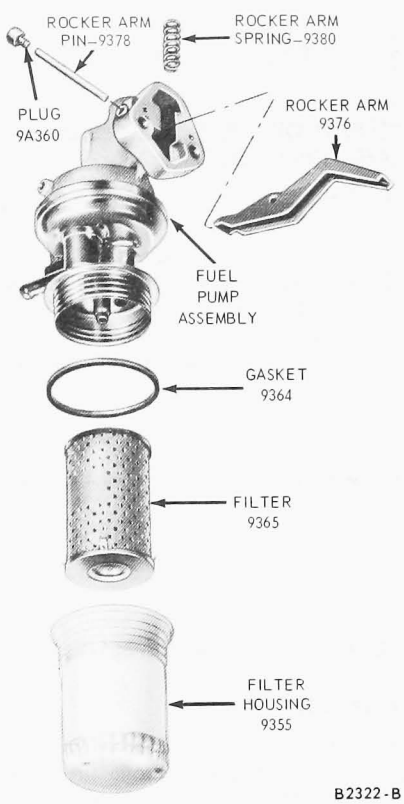

FIG. 2 Carter Sealed Design Fuel Pump Assembly— 240, 300, 360 and 390 CID Engines

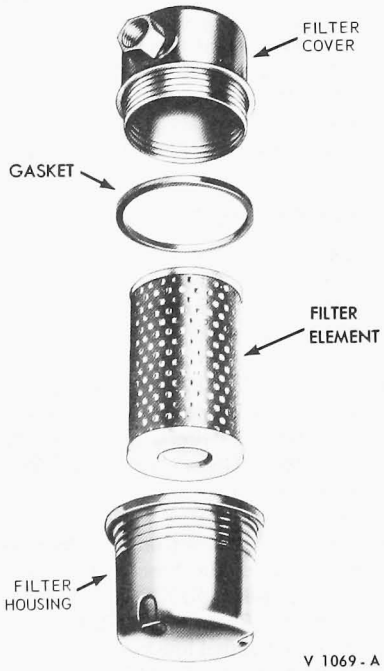

FIG. 3 Typical In-Line Fuel Filter—500-800 Series With Electric Fuel Pump

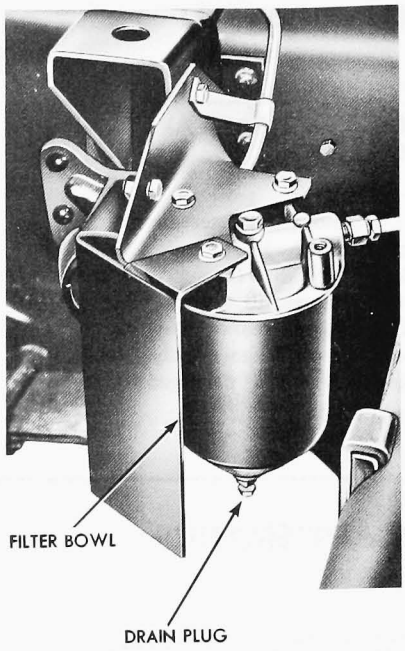

FIG. 4 Fuel Filter Installation—850-900 Series—With Electric Fuel Pump

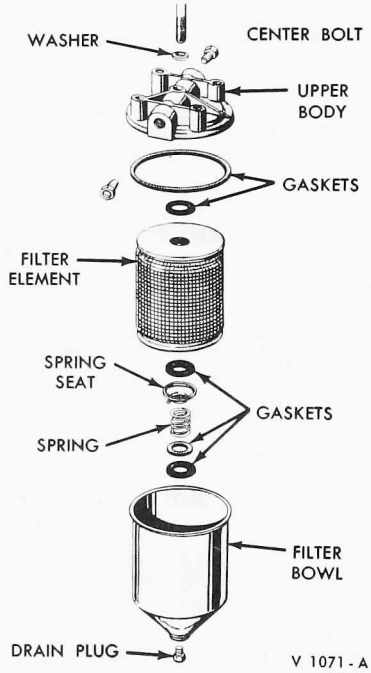

FIG. 5 Fuel Filter Assembly

A satisfactory idle should be obtainable within the range of the idle adjusting limiters, if all other engine systems are operating within specifications.

Following are the normal procedures necessary to properly adjust

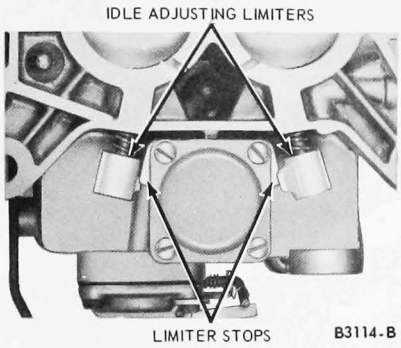

FIG. 6 Motorcraft Model 2100-D 2-V Idle Adjusting Limiters and Limiter Stops—Bottom View

the engine idle speed and fuel mixture. The specific operations should be followed in the sequence given whenever the idle speed or idle fuel adjustments are made.

In isolated cases, a satisfactory idle condition may not be achieved by performing the normal procedures. If this occurs, refer to Supplemental Idle Speed and Fuel Mixture Procedures.

Normal Idle Fuel Settings—Engine Off

1. Set the idle fuel mixture screw(s) and limiter cap(s) to the full counterclockwise position of the limiter cap(s) as illustrated in Figures 7, 8 and 9.
2. Back off the idle speed adjusting screw until the throttle plate(s) seat in the throttle bore(s).
3. Be sure the dashpot or solenoid (if so equipped) plunger is not interfering with the throttle lever (Fig. 10).

It may be necessary to loosen the dashpot to allow the throttle plate to seat in the throttle bore.

4. Turn the idle speed adjusting screw inward until it just makes the contact with the screw stop on the throttle shaft and lever assembly, and then turn the screw inward 1 1/2 turns to establish a preliminary idle speed adjustment (Figs. 10, 11 and 12).

Normal Idle Fuel Settings—Engine On

Set the parking brake while making idle mixture and speed adjustments.

1. The engine and underhood temperatures must be stabilized before idle adjustments are made. Run the engine a minimum of 20 minutes at 1500 rpm. This can be done by positioning the fast idle screw on the intermediate stop of the fast idle cam.
2. Check the initial ignition timing and the distributor advance and retard. Use an accurate reading tachometer

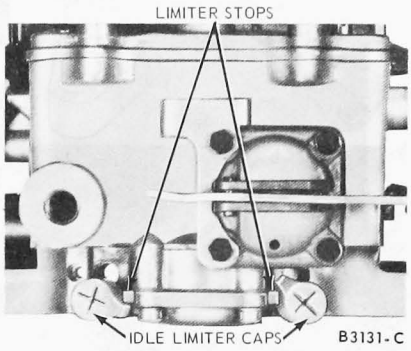

FIG. 7 Idle Fuel Mixture Limiter Caps—Motorcraft Model 2100-D 2-V

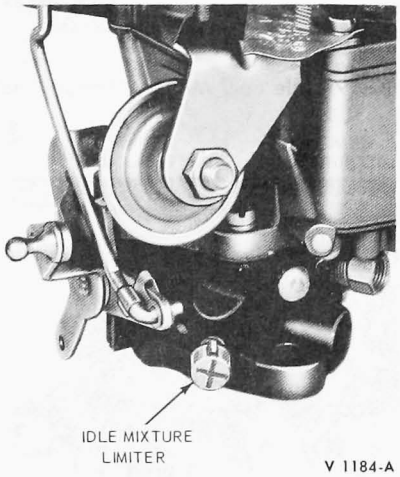

FIG. 8 Idle Fuel Mixture Limiter Cap—Carter Model YF-1-V

when checking the initial ignition timing and idle fuel mixture and speed.

3. On a vehicle with a manual-shift transmission, the idle setting must be made only when the transmission is in **neutral.**

On a vehicle with an automatic transmission, the idle adjustment is made with the parking brake on and the transmission selector lever in the Drive range, except as noted when using an exhaust gas analyzer.

4. Be sure the choke plate is in the full-open position.
5. Turn the headlights on high beam, to place the alternator under a load condition in order to properly adjust the specified engine idle.
6. The final idle speed adjustment is made with the air conditioner (if so equipped) turned OFF.
7. Adjust the engine curb idle rpm to specifications. The tachometer reading (rpm) must be taken with the air cleaner installed. On vehicles with less than 50 miles, set the idle speed approximately 25 rpm below specifications to allow for an idle rpm increase as the engine loosens up in the first 100 miles of driving.

On carburetors equipped with a solenoid throttle positioner (Fig. 12), turn the solenoid adjusting nut in or out to obtain the specified rpm. Disconnect the solenoid lead wire at the bullet connector near the wiring harness, then adjust the carburetor throttle stop screw to obtain 500 rpm with the automatic transmission in NEUTRAL. Connect the solenoid lead wire and open the throttle slightly by hand. The solenoid plunger will follow the throttle lever and remain in the fully extended position as long as the ignition is on and the solenoid energized.

If it is not possible to adjust the idle speed with the air cleaner installed, remove it and make the adjustment. Then replace the air cleaner and check again for the specified rpm.

8. Turn the idle mixture adjusting screw inward to obtain the smoothest idle possible within the range of the idle limiter.

Check for idle smoothness only with the air cleaner installed.

Supplemental Idle Speed and Fuel Mixture Procedures

If a satisfactory idle condition is not obtained after performing the preceding normal idle fuel settings, additional checks of engine systems must be performed.

1. The following items should be checked and, if required, corrected.
   a. Vacuum leak(s)—Refer to the Wiring and Vacuum Diagrams Manual (Form 7795P-73) for vacuum schematic diagrams and the location of the vacuum lines.
   b. Ignition system wiring continuity.
   c. Spark plugs.
   d. Distributor breaker point dwell angle.
   e. Distributor point condition.
   f. Initial ignition timing.

In certain instances, it may be possible that the idle condition is not as good as normally expected. It is suggested that the customer with a new vehicle be advised that the vehicle be driven 50 to 100 miles. Then, when the engine friction has been reduced, the idle condition should be improved. If, after this break-in period, the idle condition is believed to be unsatisfactory, readjust the engine idle

speed to specification and observe for a satisfactory idle.

2. If the idle condition is not improved after the items in Step 1 have been checked, perform the following engine mechanical checks:
   a. Fuel level.
   b. Crankcase ventilation system.
   c. Valve clearance, using the collapsed tappet method on hydraulic valve lifters.
   d. Engine compression.
3. After verification of all engine systems has been made, there may be isolated cases where a satisfactory idle condition has not been obtained, due possibly to a lean idle fuel mixture. If this condition is encountered, check the air-fuel ratio with the aid of an exhaust gas analyzer, and adjust the air-fuel ratio or idle co reading to specifications.

USE OF THE EXHAUST GAS ANALYZER

The use of the exhaust gas analyzer is recommended only after the Normal Fuel Setting Procedures and Additional Idle Speed and Fuel Mixture Procedures have been performed and the engine idle condition is still not satisfactory.

1. Connect a Rotunda Model ARE 27-56U or 76 Exhaust Gas Analyzer, JJRE-23 Exhaust Emission Analyzer, or equivalent A/C-powered unit, in accordance with instructions provided by the manufacturer. **All exhaust gas analyzers must be checked for proper calibration.** Rotunda analyzers must have a **Certified Calibration identification on the face of the instrument.**
2. Observe the reading obtained on the exhaust gas analyzer. **The analyzer reading must be taken with the air cleaner installed.** Refer to the specifications for the minimum air-fuel ratio or idle CO reading.
3. Turn the idle mixture adjusting screw(s), as required, within the range of the idle limiter until the specified air-fuel ratio is obtained (on 2-V and 4-V carburetors, turn the idle limiters an equal amount). **The analyzer reading must be obtained with the air cleaner installed.** Correct for any changes in engine idle speed immediately as the idle mixture screw(s) or limiters are turned. **Allow at least 10 seconds following each idle mixture screw or limiter adjustment for the analyzer reading to properly respond and stabilize.**

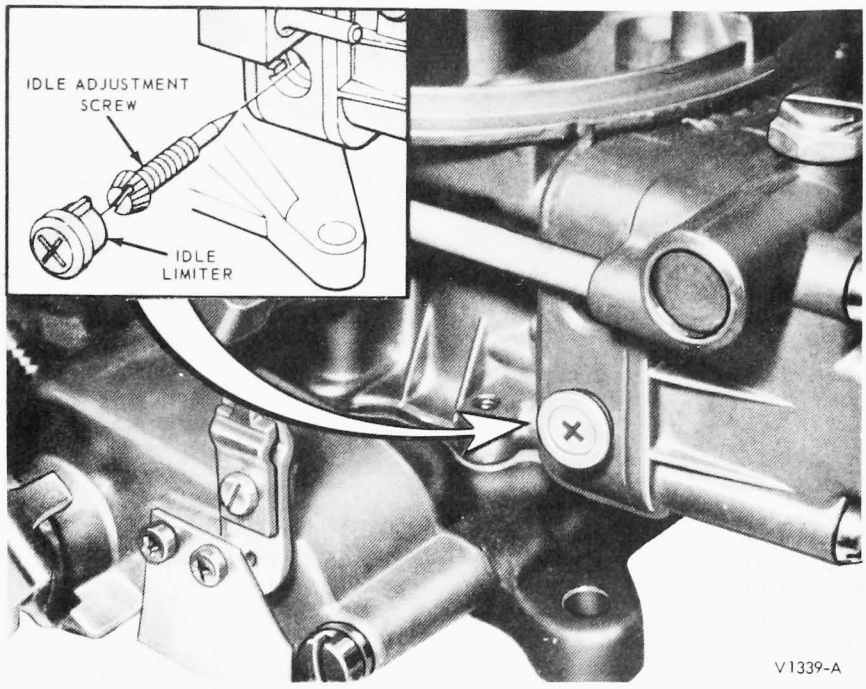

FIG. 9 Idle Fuel Mixture Limiter—Holley

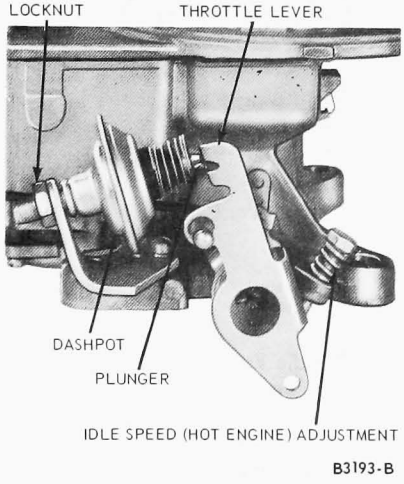

FIG. 10 Idle Speed Adjustment and Dashpot—Motorcraft Model 2100-D 2-V

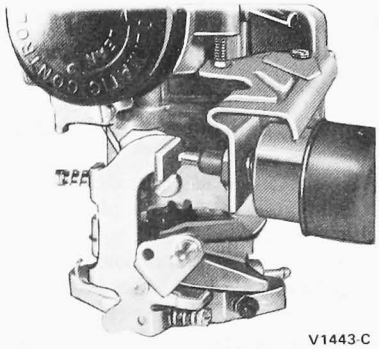

FIG. 11 Idle Speed Adjusting Screw—Carter Model YF 1-V

Verify the analyzer reading—Thermal conductivity exhaust gas analyzers will give an erroneously rich reading if the air-fuel mixture or idle CO reading is extremely lean. To check for this condition, partially hand choke the carburetor, or rapidly open and close the throttle three or four times to enrich the air-fuel mixture or idle CO reading. The analyzer meter will reflect the momentary rich condition. Then it will deflect in the lean direction as the rich condition subsides, and will gradually return to a richer reading as the excessively lean air-fuel ratio or idle CO reading is produced. **Vehicles with an automatic transmission must be in Neutral while this is being done.**

4. If the air-fuel ratio or idle CO reading is to specifications, **and the various engine systems are functioning correctly,** no further adjustments should be made.

If the air-fuel ratio or idle CO reading is not to specifications as shown by the analyzer reading, it may be corrected by altering the controlled limits of the carburetor idle fuel system. Refer to the procedures in Removal and Installation of Idle Limiter Caps.

REMOVAL AND INSTALLATION OF IDLE LIMITER CAPS

1. Remove the plastic limiter caps by cutting with side-cutter pliers and knife. After the cut is made, carefully pry the limiter apart. **On some carburetors, it may be necessary to remove the carburetor to remove the limiters.**

On Holley 4-V carburetors with the limiters installed in the metering block, pry the limiters off with a screwdriver.

2. After the limiters are removed, set the carburetor to the correct air-fuel ratio, using the exhaust gas analyzer.
3. When the air-fuel ratio is within specifications, install colored plastic service limiter caps.

When installing a limiter cap, use care not to turn the idle mixture screw with the cap. Position the cap so that it is in the maximum counterclockwise position with the tab of the limiter against the stop on the carburetor.

The idle mixture adjusting screw will then be at the maximum allowable outward, or rich, setting.

To install the service limiter cap, use a straight, forward pushing force with thumb pressure or a 3/8-inch socket wrench extension.

4. Recheck the air-fuel ratio or idle CO reading with the air cleaner installed, using the exhaust gas analyzer to make sure the limiter caps are properly installed. After the idle limiter has been reset and the air-fuel ratio or idle CO reading and idle condition are satisfactory, stamp or scribe the letter **R** on the carburetor identification tag just above the name **MOTORCRAFT to indicate that the carburetor has been reworked.**

CARTER MODEL YF 1-V

Fast Idle Cam Index Setting

1. Position the fast idle screw on the kickdown step of the fast idle cam against the shoulder of the high step.
2. Adjust by bending the choke plate connecting rod to obtain the specified clearance between the lower edge of the choke plate and the carburetor bore.

Fast Idle Speed—Manual Choke Carburetor

1. Open the throttle plate and hold the choke plate fully closed to allow the fast idle cam to rotate to the fast idle position.
2. Set the fast idle speed, using the fast idle adjusting screw.

Fast Idle Speed—Automatic Choke Carburetor

The fast idle adjusting screw contacts one edge of the fast idle cam.

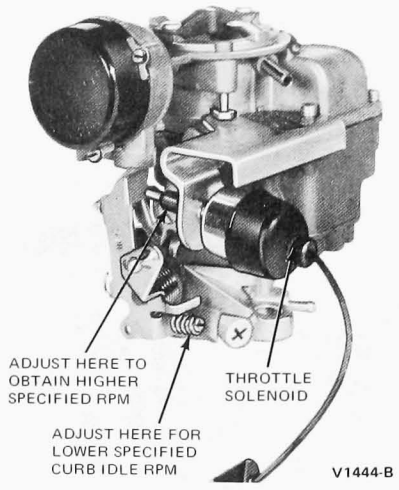

FIG. 12 Carter Model YF 1-V with Throttle Solenoid Positioner

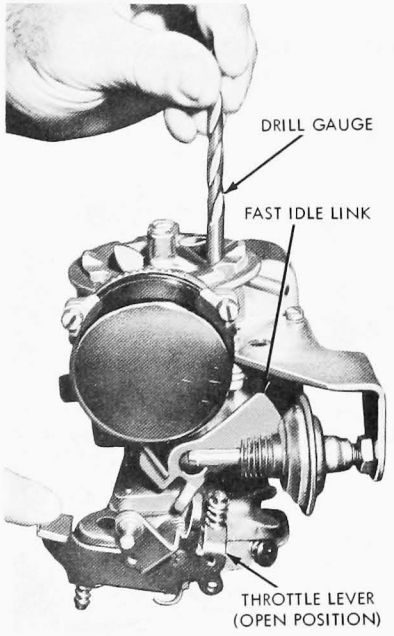

FIG. 13 Choke Plate Clearance Adjustment (De-Choke)

The cam permits a faster engine idle speed for smoother running when the engine is cold during choke operation. As the choke plate is moved through its range of travel from the closed to the open position, the fast idle cam pick-up lever rotates the fast idle cam. Each position on the fast idle cam permits a slower idle rpm as engine temperature rises and choking is reduced.

Make certain the curb idle speed and mixture are adjusted to specification before attempting to set the fast idle speed.

1. With the engine operating temperature normalized (hot), air cleaner removed and the tachometer attached, manually rotate the fast idle cam until the fast idle adjusting screw rests on the specified step of the cam.
2. Turn the fast idle adjusting screw inward or outward as required to obtain the specified fast idle rpm.

Anti-Stall Dashpot

The engine idle mixture speed must be properly adjusted before adjusting the anti-stall dashpot.

1. Remove the air cleaner.
2. Loosen the anti-stall dashpot locknut.
3. With the choke plate open, hold the throttle plate closed (idle position), and check the clearance between the throttle lever and dashpot plunger tip with a feeler gauge of the specified clearance dimension. Turn the dashpot inward or outward to obtain the specified clearance and tighten the lock nut. **The clearance must be measured with the plunger fully depressed.**

Automatic Choke Thermostatic Spring Housing Adjustment

The automatic choke has an adjustment to control its reaction to engine temperature. By loosening the clamp screws that retain the thermostatic spring housing to the choke housing, the spring housing can be turned to alter the adjustment. Refer to the specifications for the proper setting.

1. Remove the air cleaner assembly from the carburetor.
2. Loosen the thermostatic spring housing clamp attaching screws. Set the spring housing to the specified index mark and tighten the clamp attaching screws.
3. If other carburetor adjustments are not required, install the air cleaner assembly on the carburetor.

De-Choke Clearance

1. Remove the air cleaner, then remove the choke thermostatic spring housing from the carburetor.
2. Hold the throttle plate fully open and close the choke plate as far as possible without forcing it. Use a drill of the proper diameter to check the clearance between the choke plate and air horn (Fig. 13).
3. If the clearance is not within specification, adjust by bending the arm on the choke trip lever. Bending the arm downward will increase the clearance, and bending it upward will decrease the clearance. Always recheck the clearance after making any adjustment.

4. Install the baffle plate, gasket and thermostatic coil housing. Be sure the thermostatic spring engages the tang on the choke lever and shaft assembly.
5. Set the thermostatic choke housing to the specified index mark and tighten the attaching screws.

Pulldown Clearance

1. Remove the air cleaner. Remove the choke thermostatic spring housing from the carburetor.
2. Bend a 0.026 inch diameter wire gauge at a 90 degree angle approximately 1/8 inch from one end. Insert the bent end of the gauge between the choke piston slot and the right hand slot in the choke housing. Rotate the choke piston lever counterclockwise until the gauge is snug in the piston slot.
3. Exert a light pressure on the choke piston lever to hold the gauge in place, then use a drill gauge with a diameter equal to the specified clearance between the lower edge of the choke plate and the carburetor bore to check clearance (Fig. 14).
4. To adjust the choke plate pulldown clearance, bend the choke piston lever as required to obtain the specified setting. Remove the choke piston lever for bending to prevent distorting the piston link, causing erratic choke operation.
5. Install the choke thermostatic spring housing and gasket. Set the housing to specifications.

MOTORCRAFT MODEL 2100-D

Fast Idle Speed Adjustments

The fast idle adjusting screw (Fig. 15) contacts one edge of the fast idle cam. The cam permits a faster engine idle speed for smoother running when the engine is cold during choke operation. As the choke plate is moved through its range of travel from the closed to the open position, the fast idle cam pick-up lever rotates the fast idle cam. Each position of the fast idle cam permits a slower idle rpm as engine temperature rises and choking is reduced. On vehicles equipped with a spark delay device, by-pass the delay device by connecting a vacuum line directly from the carburetor spark port to the advance side of the distributor. Also, on vehicles equipped with EGR system, disconnect and plug the vacuum line to the EGR valve before setting the fast idle speed.

Make certain the idle (hot engine) speed and mixture is adjusted to specification before attempting to set the fast idle speed.

1. With the engine operating temperature normalized (hot), air cleaner removed and the tachometer attached, manually rotate the fast idle cam until the fast idle adjusting screw rests on the **center** step on the cam.
2. Start the engine, and turn the fast idle adjusting screw inward or outward as required to obtain the specified idle rpm.

Anti-Stall Dashpot Adjustment

The anti-stall dashpot adjustment is made with the air cleaner removed.

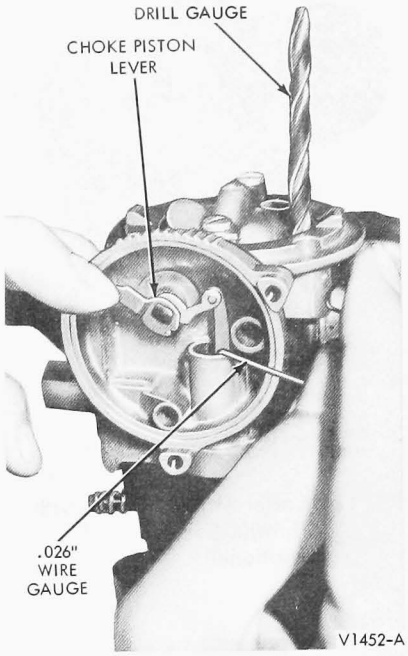

FIG. 14 Pulldown Clearance Adjustment—Carter Model YF 1-V

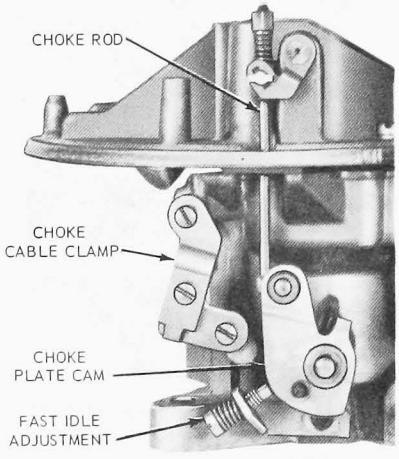

FIG. 15 Fast (Cold Engine) Idle Speed Adjustment—Motorcraft Model 2100-D 2-V

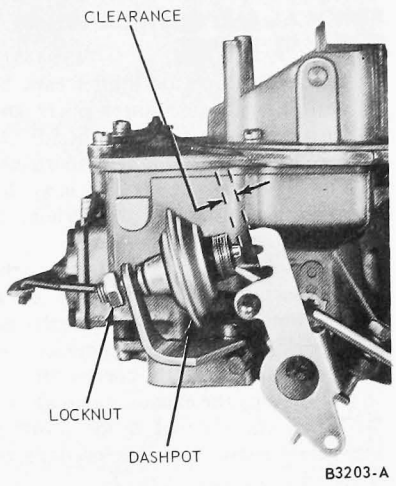

FIG. 16 Anti-Stall Dashpot Adjustment—Motorcraft Model 2100-D 2-V

1. With the engine idle speed and mixture properly adjusted, and the engine at normal operating temperature, loosen the anti-stall dashpot locknut (Fig. 16).
2. Hold the throttle in the closed position and depress the plunger with a screwdriver blade. Measure the clearance between the throttle lever and the plunger tip. Turn the anti-stall dashpot in a direction to provide the specified clearance between the tip of the plunger and the throttle lever. Tighten the locknut to secure the adjustment.
3. Check the accelerating pump stroke for adjustment. Install the air cleaner.

Accelerating Pump Adjustment

The accelerating pump stroke has been set to help keep the exhaust emission level of the engine within the specified limits. The additional holes provided for pump stroke adjustment are for adjusting the stroke for specific engine applications. **The stroke should not be changed from the specified setting.**

If the pump stroke has been changed from the specified setting, refer to the following instructions to correct the stroke to specifications.

The throttle shaft lever (overtravel lever) has 4 holes and the accelerating pump link has 2 holes (Fig. 17) to control the accelerating pump stroke.

The accelerating pump operating rod should be in the specified hole in the overtravel lever and the inboard hole (hole closest to the pump plunger) in the accelerating pump link (Fig. 17).

1. To release the rod from the retainer clip, press the tab end of the clip toward the rod; then, at the same

time, press the rod away from the clip until it is disengaged.
2. Position the clip over the specified hole in the overtravel lever. Press the ends of the clip together and insert the operating rod through the clip and the overtravel lever. Release the clip to engage the rod.

Choke Plate Pulldown Clearance Adjustment— Manual Choke

1. Remove the air cleaner. Pull the choke cam and lever to the full choke position. Insert the specified size gauge or drill between the downward side of the choke plate and the air horn wall (Fig. 18). The gauge or drill will open the choke plate against the pull-down spring tension.
2. Adjust the choke operating (pull-down) rod adjusting nut to compress the spring to just contact the plastic swivel (Fig. 18).

CHOKE PLATE PULLDOWN AND FAST IDLE CAM CLEARANCE

CHOKE PLATE PULLDOWN

1. Remove the air cleaner.
2. With the engine at normal operating temperature, loosen the choke thermostatic spring housing retainer screws and set the housing 90 degrees in the **rich** direction.
3. Disconnect and remove the choke heat tube from the choke housing.
4. Turn the fast idle adjusting screw outward **one full turn.**
5. Start the engine, then check for specified clearance between the lower edge of the choke plate and the air horn wall (Fig. 19).
6. Because the choke plate pulldown is set in production by means of an air-fuel meter, no specific clearance is indicated for pulldown adjustment. If the vehicle shows indication of leaness during cold starting, decrease the clearance between the choke plate and the air horn wall by 0.020 inch. If the engine shown signs of an overrich condition during cold starting, increase the pulldown clearance by 0.020 inch. If additional adjustment is required always make the adjustments is Steps of 0.020 inch. If the original pulldown adjustment is lost, set the clearance between the choke plate and the air horn to 0.160 inch. Then adjust as required in steps of 0.020 inch.
7. Connect the choke heat tube and set the choke thermostatic spring housing to specifications. Adjust the

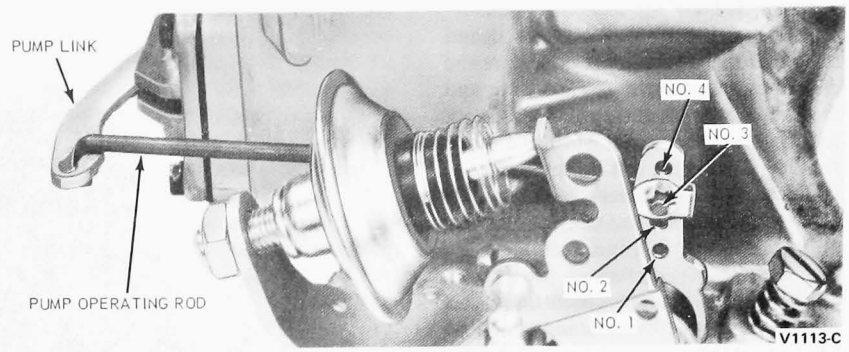

FIG. 17 Accelerating Pump Stroke Motorcraft Model 2100-D 2-V

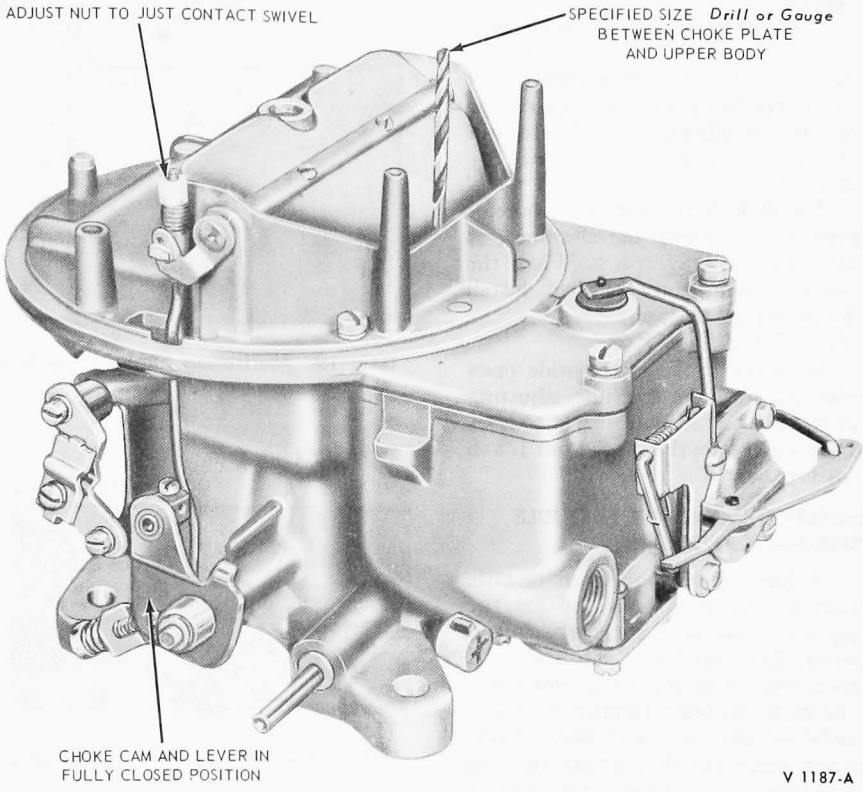

FIG. 18 Adjusting Choke Plate Pulldown Clearance— Motorcraft Model 2100-D 2-V with Manual Choke

FAST IDLE CAM CLEARANCE

1. Rotate the choke thermostatic spring housing 90 degrees in the rich direction.
2. Position the fast idle speed screw on the high step of the cam.
3. Depress the choke pulldown diaphragm against the diaphragm stop screw to place the choke in the pulldown position.
4. While holding the choke pulldown diaphragm depressed, open the throttle slightly and allow the fast idle cam to fall.
5. Close the throttle and check the position of the fast idle cam or lever. The screw should contact the cam at the V mark on the cam.
6. Adjust the fast idle cam adjusting screw to obtain the proper setting.
4. Set the choke thermostatic spring housing to specifications. Adjust the anti-stall dashpot, idle speed and fuel mixture.

HOLLEY 2-V AND 4-V CARBURETOR FAST IDLE SPEED—INITIAL SETTING ADJUSTMENT

If the carburetor was removed from the vehicle for replacement or overhaul procedures, it is recommended that an initial fast idle adjustment be performed as follows.

330 and 361 2-V

With the throttle plates closed and the choke plate wide open, measure the clearance between the fast idle cam and the fast idle screw. If the clearance is not to specifications, turn the fast idle screw the required amount to increase or decrease the clearance. A 1/4 turn in or out will alter the clearance by approximately 0.008 inch.

391 4-V

With the primary throttle plates closed, measure the clearance between the fast idle cam and the head of the fast idle cam and the head of the fast idle screw (Fig. 20). If the clearance is not to specifications, remove the governor housing.

Turn the fast idle screw the required amount to increase or decrease the clearance. **A 3/16 inch wrench with a 90 degree head will be required to perform the adjustment.** A 1/4 turn in or out will alter the clearance by approximately 0.008 inch.

Install the housing on the carburetor governor and check the clearance, as outlined in Paragraph 2. When the clearance is properly adjusted, install the governor housing.

401, 477 and 534 4-V

With the choke in the wide open position, turn the fast idle adjusting screw (Fig. 21) in until it just touches the fast idle cam; then back it off 1/8 to 1/4 turn.

HOLLEY 2-V AND 4-V FAST IDLE SPEED—FINAL SETTING

A hand (cable) operated throttle control has been provided for the engines in various vehicle models and series. The throttle is actuated by a knob, located on the instrument panel. The hand operated throttle control is useful for maintaining constant engine speed when running power take-off equipment or when performing certain service operations.

The fast (cold engine) idle speed is adjusted with the hand throttle control knob pushed fully inward. The idle (hot engine) speed must be adjusted to specification before the fast idle speed can be adjusted.

330 and 361 2-V V-8 and 391 4-V V-8 Engines

The fast idle speed adjustment screw for the carburetor on a 330 and 361 2-V V-8 engine is located in the throttle housing. The fast idle speed adjustment screw for the 391 4-V V-8 engine is located in the governor housing (Fig. 20).

The fast idle adjustment screw contacts the fast idle cam during the engine warm-up period and controls the fast (cold engine) idle speed.

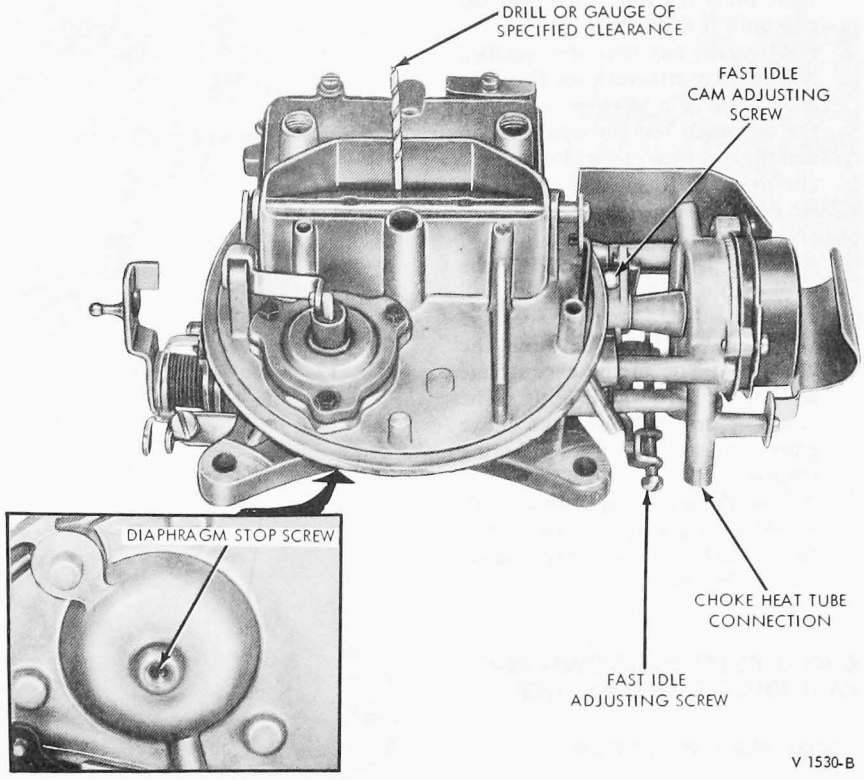

FIG. 19 Measuring Choke Plate Pulldown

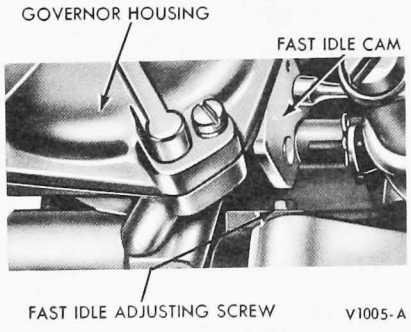

FIG. 20 Fast (Cold Engine) Idle Speed Adjustment—391 4-V Engine

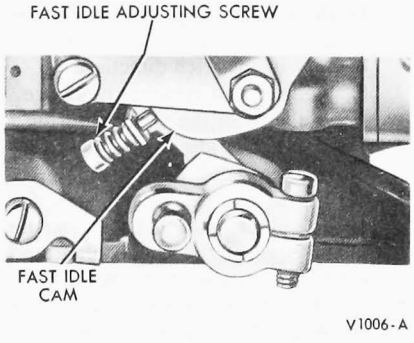

FIG. 21 Fast (Cold Engine) Idle Speed Adjustment— 401, 477 and 534 4-V V-8 Engines

1. Adjust the idle (hot engine) speed and mixture to specifications before attempting to set the fast (cold engine) idle speed. **The fast idle speed adjustment is made with the engine at normal, stabilized operating temperature.**
2. With the engine operating and a tachometer attached to the engine, disconnect the choke cable housing from the choke cable bracket clamp. Pull the choke cable housing rearward until the choke plate operating lever is against the stop on the choke cable bracket. **Hold the choke plate open to the choke pulldown limit, to keep the engine running.**
3. Check the fast (cold engine) rpm. If the idle rpm is not to specification, turn the fast idle screw clockwise with a 3/16 inch wrench to decrease the engine rpm or counterclockwise to increase the rpm. **On a 4-V carburetor, a 3/16 inch wrench with a 90 degree head will be required to perform the adjustment.**
4. Turn off the engine and remove the tachometer.
5. Push the choke lever, cable and

housing forward to the full choke position and clamp the choke cable housing to the choke cable bracket.
6. Install the air cleaner assembly if other adjustments are not required.

The fast idle adjustment screw on the left side of the carburetor contacts the fast idle cam during the engine warm-up period and controls the fast (cold engine) idle speed (Fig. 20).

401, 477 and 534 4-V V-8 Engines

1. Adjust the idle (hot engine) speed and mixture before attempting to set the fast (cold engine) idle speed. **The fast idle speed adjustment is made with the engine at a normal, stabilized operating temperature.**
2. With the choke in the wide open position, turn the fast idle adjusting screw (Fig. 20) in until it just touches the fast idle cam; then back it off 1/8 to 1/4 turn.

HOLLEY CARBURETOR ACCELERATING PUMP LEVER ADJUSTMENT

1. Using a feeler gauge and with the throttle plates (primary throttle plates on 4-V carburetors) in the wide open position, there should be the specified clearance between the accelerating pump operating lever adjustment screw head and the pump arm when the pump arm is depressed manually.
2. If adjustment is required, loosen the adjusting screw locknut and turn the adjusting screw in to increase the clearance and out to decrease the clearance. **One-half turn of the adjusting screw is equal to approximately 0.015 inch.** When the proper adjustment has been obtained hold the adjustment screw in position with a wrench and tighten the lock nut.
3. Perform an accelerating pump stroke adjustment, if required.

HOLLEY CARBURETOR ACCELERATING PUMP STROKE ADJUSTMENT

The accelerating pump stroke has been set to help keep the exhaust emission level of the engine within the specified limits. The additional holes provided for pump stroke adjustment are for adjusting the stroke for specific engine applications. **The stroke should not be changed from the specified setting.**

If the pump stroke has been changed from the specified setting refer to the following instructions to correct the stroke to specifications.

If a change in the adjustment is required, make certain the proper hole (top or bottom) in plastic accelerating pump cam, located behind the throttle lever, is properly aligned (indexed) with the numbered hole (top or bottom) in the throttle lever before installing the attaching screw.

SPECIFICATIONS

Refer to the Truck Specifications Book for Fuel System Specifications.

PART 50-26 Exhaust Systems

COMPONENT INDEX	Page	COMPONENT INDEX	Page
MAINTENANCE		Exhaust System Inspection	26-01
Exhaust Control Valve Operation	26-01		

MAINTENANCE

CHECK EXHAUST CONTROL VALVE FOR FREE OPERATION (IF SO EQUIPPED)

Check the thermostatic spring of the valve to make sure it is hooked on the stop pin. The spring stop is at the top of the valve housing when the valve is properly installed.

To check the exhaust control valve, make sure the spring holds the valve closed. Actuate the counterweight by hand to make sure it moves freely through approximately 90 degrees of rotation without binding.

The valve is closed when the engine is cold (Fig. 1). However, a properly operating valve will open when very light finger pressure is applied to the counterweight. Rapidly accelerate the engine to make sure the valve momentarily opens. The valve is designed to open when the engine is at normal operating temperature and is operated at high rpm.

Lubricate and free the valve with the specified solvent (Part 50-03) if the valve is sluggish or stuck.

INSPECT EXHAUST SYSTEM

The exhaust system must be free of leakage, binds, groundings, excessive vibration and restrictions. Check the exhaust manifold and pipe connections to be sure they are securely attached.

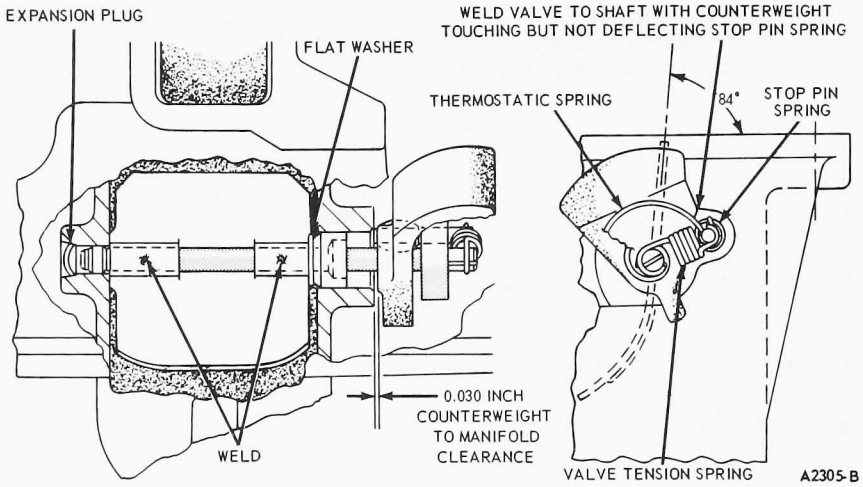

FIG. 1 Engine Exhaust Control Valve—Typical

Leaks can usually be detected visually, or in some cases, a whistling noise may be heard at the pipe connections. Check the various sections of the exhaust system for signs of leaking or burning through.

Muffler inlet and outlet pipes and the various pipe connectors must overlap sufficiently to prevent leakage, and provide enough overlap to support proper tightening of the retaining clamp(s). Replace all sections that show signs of burning through.

Exhaust system vibration, grounding or binds are usually caused by: loose, broken or improperly aligned clamps or brackets; improper installation of the inlet pipe flange on the exhaust manifold, or improper pipe connections. Any of the aforementioned conditions may cause changes to the clearances of the exhaust system components. If any of these conditions exist, the exhaust system components must be checked and adjusted to make certain clearances are maintained.

Radiator Coolant Level – Check	27-01
SPECIFICATIONS	27-04

PRE-DELIVERY

CHECK THE COOLING SYSTEM, HOSES AND LINES

Check for leaking radiator hoses and tighten if necessary.

Make sure all supporting brackets for hoses are in place and that the hoses are properly installed in the supports.

CHECK RADIATOR COOLANT LEVEL (ENGINE AT NORMAL OPERATING TEMPERATURE)

CAUTION: Avoid injury when checking a hot engine. Muffle the radiator cap in a thick cloth and turn it slowly counterclockwise only until the pressure starts to escape. After the pressure has completely dissipated, finish removing the cap.

On conventional radiators, the coolant level should be approximately 1 inch below the bottom of the radiator filler neck. On vehicles with an expansion tank, fill the tank 2/3 full.

On L-Series gasoline and Ford V-8 Diesel engines, with crossflow radiators, fill until the coolant is visible through the sightglass— engine cold. (Caution—Do not operate engine if coolant level is below sightglass.)

On L-Series Cummins and Detroit Diesel engines, fill until the coolant is visible through the bottom of the upper sightglass with engine cold. (Caution—Do not operate engine if coolant level is below the lower sightglass.)

When adding coolant, a mixture of Ford Permanent Anti-Freeze and water is recommended. To avoid possible chemical damage to the cooling system, do not mix different brands of anti-freeze no use other than a permanent anti-freeze meeting Ford specification ESE-M97B18-C.

Keep the freeze protection at an adequate level for the temperatures which may occur in the area in which the vehicle will be operated. It should be maintained at least to 0 degrees F to provide adequate corrosion and boiling protection. Ford Permanent Anti-freeze may be added undiluted if anti-freeze protection below -35 degrees F is required. Refer to the coolant mixture charts on the container.

Tap water may be used in the mixture except where it is known to be very hard or to have a high alkaline content.

CHECK ANTI-FREEZE PROTECTION

Be sure the engine is at operating temperature. Check the anti-freeze in the cooling system by using a permanent anti-freeze test hydrometer. Standard protection is to -20 degrees F. (-35 degrees F. for Canadian and Alaskan vehicles) with a solution of Ford Permanent Anti-Freeze and water. The freeze protection of engine should be maintained at an adequate level for the temperatures which may occur in the area in which the vehicle will be operated. Regardless of the freeze protection required for gasoline engines during cold weather, it must be maintained at least to 0 degrees F. to provide adequate corrosion and boiling protection.

LUBRICATION

LUBRICATE RADIATOR SHUTTER ASSEMBLY

All vanes should move freely without binding. On all except W-Series, the shutter blade pivot rod and arms should be lubricated with SAE 10W engine oil. On W-Series lubricate the shutter control shaft bushings with SAE 10W engine oil.

MAINTENANCE

COOLANT

Correct coolant level is essential for maximum circulation and adequate cooling. In addition, for the cooling system to perform its function, it must receive proper care. This includes keeping the radiator fins clean and a periodic inspection of the cooling system for leakage.

Use care when removing the radiator cap to avoid injury from escaping steam or hot water.

In production, the cooling system is filled with a 45-55 solution of Ford Permanent Anti-freeze and water (50-50 solution for Canadian, Alaskan and export delivery) which prevents corrosion, keeps the cooling system clean, provides anti-freeze protection to -20 degrees F. in winter (-35 degrees for Canadian, Alaskan and export delivery) and provides for higher summer operation temperatures.

For the most effective cooling system operation, this mixture strength should be maintained all year around and in all climates.

You should keep the freeze protection of your engine at an adequate level for the temperatures which may occur in the area in which your truck will be operated. Regardless of the freeze protection required for your climate during cold weather, it must be maintained at least to 0 degrees F. to provide adequate corrosion and boiling protection.

All coolant added should be the specified mixture of Ford Permenent Anti-freeze and water.

Ordinary tap water may be used in an emergency **except in areas where the water is known to be exceptionally hard or to have a high alkali content. The cooling system should be drained and flushed and the proper mixture of anti-freeze added as soon as possible, however.**

To avoid possible overheating in very hot weather, do not use mixtures with more than 50 percent anti-freeze except in areas where anti-freeze protection below -35 degrees F is required. In this case, refer to the coolant mixture chart on the Ford Permanent Anti-freeze container.

Do not add any radiator sealers containing water soluble oil to the cooling system as it will make the corrosion resistor (water filter) inoperative.

RADIATOR COOLANT MIXTURE

To prevent damage to the cooling system during periods of below freezing ambient temperature, when water or anti-freeze is added to the supply tank, always operate the engine at fast idle for 30 minutes before letting the truck stand with the engine off for prolonged periods. This will allow a uniform mixture throughout the cooling system and prevent damage by freezing, when sufficient anti-freeze is used.

A standard ethylene glycol hydrometer can be used to check the protection level of the long-life coolant.

DRAINING AND FILLING THE COOLING SYSTEM

TRUCKS WITH GASOLINE ENGINES

To prevent loss of anti-freeze when draining the radiator attach a hose on the radiator drain cock and drain the coolant from the radiator into a clean container.

To drain the radiator, open the drain cock located at the bottom of the radiator and remove the radiator or supply tank cap. The cylinder block of the V-8 engine is drained by removing the drain plugs located on both sides of the block. The 6-cylinder engines have one drain plug located at the left rear of the cylinder block.

To fill the cooling system, install the cylinder block drain plug(s) and close the radiator drain cock. On 100-350 Series trucks, disconnect the heater outlet hose at the water pump to bleed or release trapped air in the system. When the coolant begins to escape, connect the heater outlet hose.

On C-800-900 Series trucks with super duty engines, open the air vent valve located at the front of the intake manifold to bleed the system. When coolant begins to escape at the opening, close the valve finger-tight. Do not overtighten, as the air vent valve is designed to be closed finger-tight only.

On downflow radiators, operate the engine and add more coolant, if necessary, to fill the radiator to the proper level. On trucks without a supply tank, fill the radiator one inch above the baffles (or core). On trucks equipped with a supply tank, fill the supply tank 2/3 full.

On L-Series equipped with crossflow radiators, fill until the coolant is 1 inch from the top of the tank-engine cold (Caution—Do not operate engine if coolant level is below sightglass.)

After the initial fill, the coolant level will drop approximately 1 quart after the engine has been operated about 20 minutes at 2000 rpm. This is due to the displacement of entrapped air.

CHECK ANTI-FREEZE PROTECTION

Be sure the engine is at operating temperature. Check the anti-freeze in the cooling system by using a permanent anti-freeze test hydrometer. Standard protection is to -20 degrees F. (-35 degrees F. for Canadian and Alaskan vehicles) with a solution of Ford Permanent Anti-Freeze and water. The freeze protection of engine should be maintained at an adequate level for the temperatures which may occur in the area in which the vehicle will be operated. Regardless of the freeze protection required for gasoline engines during cold weather, it must be maintained at least to 0 degrees F. to provide adequate corrosion and boiling protection.

CHECK RADIATOR COOLANT LEVEL (ENGINE AT NORMAL OPERATING TEMPERATURE)

CAUTION: Avoid injury when checking a hot engine. Muffle the radiator cap in a thick cloth and turn it slowly counterclockwise only until the pressure starts to escape. After the pressure has completely dissipated, finish removing the cap.

On conventional radiators, the coolant level should be approximately 1 inch below the bottom of the radiator filler neck. On vehicles with an expansion tank, fill the tank 2/3 full.

On L-Series gasoline and Ford V-8 Diesel engines, with crossflow radiators fill until the coolant is visible through the sightglass—engine cold. (Caution—Do not operate engine if coolant level is below sightglass.)

On L-Series Cummins and Detroit Diesel engines, fill until the coolant is visible through the bottom of the upper sightglass with engine cold. (Caution—Do not operate engine if coolant level is below the lower sightglass.)

When adding coolant, a mixture of Ford Permanent Anti-Freeze and water is recommended. To avoid possible chemical damage to the cooling system, do not mix different brands of anti-freeze nor use other than a permanent anti-freeze meeting Ford specificaiton ESE-M97B18-C.

Keep the freeze protection at an adequate level for the temperatures which may occur in the area in which the vehicle will be operated. It should be maintained at least to 0 degrees F to provide adequate corrosion and boiling protection. Ford Permanent Anti-Freeze may be added undiluted if anti-freeze protection below -35 degrees F is required. Refer to the coolant mixture charts on the container.

Tap water may be used in the mixture except where it is known to be very hard or to have a high alkaline content.

RADIATOR SIGHT GLASS—L-SERIES

Sight glass should be cleaned when coolant level is difficult to see. Unscrew sight glass from radiator. Wipe the glass with a clean damp cloth to remove any residue. Replace the sight glass in the radiator and torque to 9-13 in-lbs.

COOLANT RECOVERY SYSTEM

F-100-250 TRUCK, ECONOLINE E-100-300 W/240 CID ENGINE MANUAL TRANSMISSION, STANDARD COOLING, BRONCO WITH AUTOMATIC TRANSMISSION

The engine coolant recovery system incorporates a new radiator pressure cap and a new radiator coolant recovery reservoir assembly (Fig. 1).

When the cooling system has been drained for replacement of hoses, thermostat, engine repair, etc.; the following radiator coolant refilling instructions are recommended.

1. Fill the radiator, through the filler cap opening of the radiator upper tank completely full. The **locking type radiator cap may be removed by turning to the stop and, pressing down on the cap, force the cap past the stop tangs on the filler neck. When filling radiator, the engine should be running at idle speed to circulate the coolant and eliminate any trapped air in the system.**
2. Install the radiator cap.
3. Fill the coolant reservoir with one quart of coolant.
4. Operate the engine until it reaches normal temperature. Check the coolant reservoir to see if the coolant level is at the **Engine Hot** level. If necessary, add coolant to bring it to this level.

Note: The new design locking type radiator cap assembly should not be removed to check the coolant level. The filler neck of the radiator upper tank incorporates a built-in stop that prevents complete removal of the radiator cap under normal conditions. If necessary, add coolant to the reservoir only.

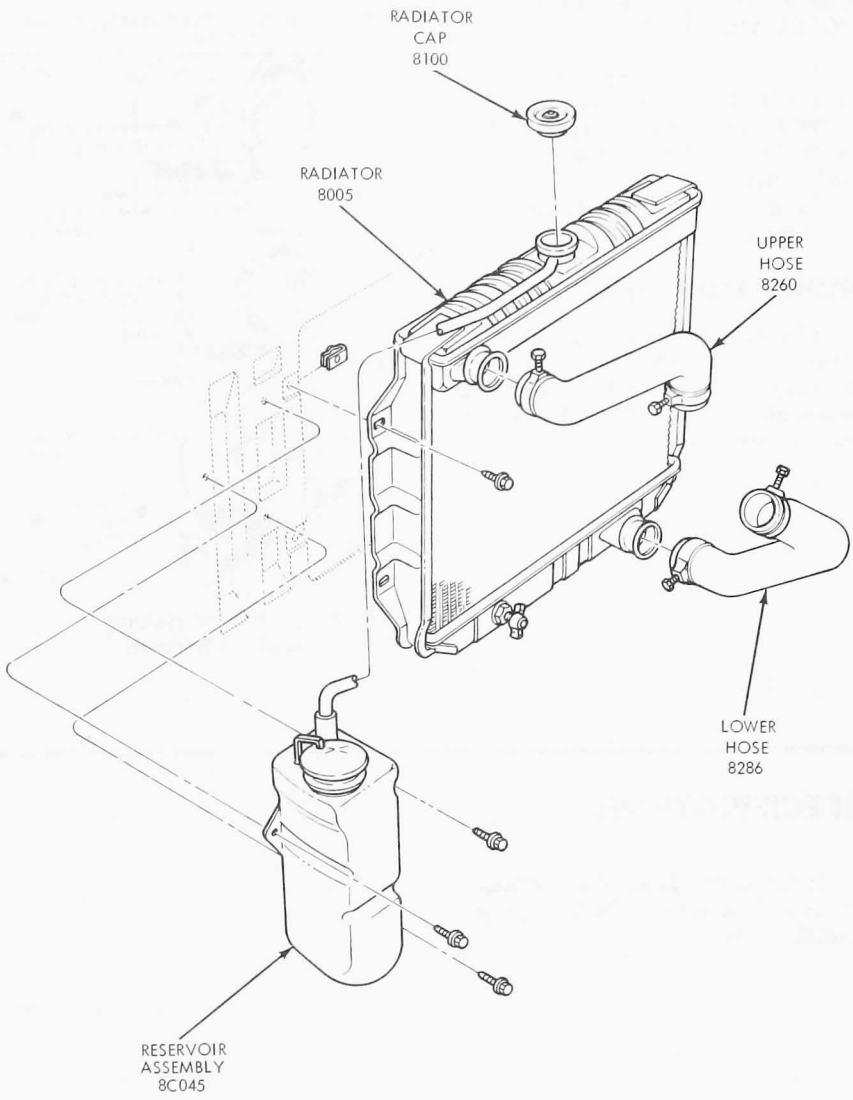

FIG. 1 Coolant Recovery System

CLEAN SHUTTERSTAT INTEGRAL AIR FILTER (EXCEPT W-SERIES)

The shutterstat has an integral air filter element which should be inspected, and if necessary, thoroughly cleaned every 24,000 miles.

However, in order to remove the element for cleaning, an end cap wrench, Kysor Tool No. B-18475, and a fabricated holding tool are required. The holding tool can be fabricated locally from steel tubing that is readily available. Fig. 2 outlines instructions for fabricating the tool.

1. Drain the air system. Install the fabricated holding tool (Fig. 2) over the end of the shutterstat.
2. Loosen the end cap using Kysor Tool B-18475 and remove the cap, cap gasket, spring washer, filter element and air filter gasket. Discard the gaskets.
3. Clean the filter element in solvent and dry with compressed air.
4. Place a new filter gasket in the shutterstat body. Then, install the air filter element, spring washer and end cap using a new end cap gasket. Torque the cap to 45 ft-lbs.
5. Start the engine and check the shutterstat for leaks.

CHECK THE COOLING SYSTEM, HOSES AND LINES

Inspect the cooling system hoses for evidence of cracking, checking for extreme weathering. Replace cracked hoses. Check for leaking or porous hoses and tighten or replace.

Inspect the radiator core and tanks for seepage or leaks.

INSPECT RADIATOR SHUTTERS

Check for smooth closing of shutters when engine is started, and for smooth opening as engine reaches operating temperature. Check blades for proper sealing. Adjust as required.

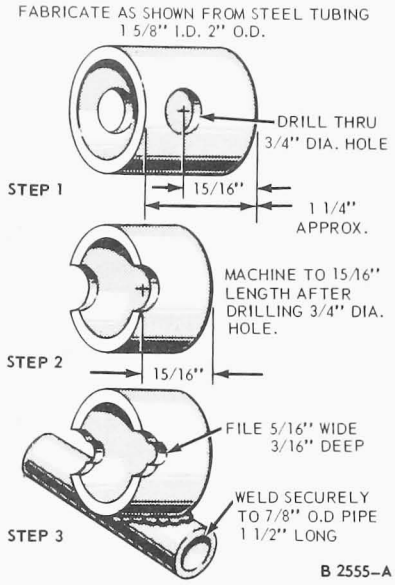

FIG. 2 Shutterstat Holding Tool—Fabricated

SPECIFICATIONS

Refer to the Truck Shop Manual, Volume Two, for the Cooling System Specifications.

PART 50-31 Charging System

COMPONENT INDEX	Page
MAINTENANCE	
Charging System Tests	31-02
Electrical Connections – Clean and Tighten	31-02
PRE-DELIVERY	
Alternator and Voltage Regulator Operation	31-01
PRE-DELIVERY (Cont.)	
Battery Cables – Check	31-01
Battery Fluid Level Check	31-01
Battery State of Charge Check	31-01
SPECIFICATIONS	31-07

PRE-DELIVERY

CHECK BATTERY STATE OF CHARGE

When corrected to 80 degrees F. the battery should have a specific gravity reading of not less than 1.250. If the battery requires charging, refer to the specific gravity chart in the specifications section.

Warning

Batteries contain SULFURIC ACID.In case of acid contact with skin, eyes, or clothing, FLUSH IMMEDIATELY WITH WATER FOR A MINIMUM OF FIVE MINUTES. Get "on-the-spot" medical attention immediately.

Hydrogen and oxygen gases are produced during normal battery operation. This gas mixture can explode if flames or sparks are brought near the battery. When charging or using battery in an enclosed space always provide ventilation.

Particular care should be used when connecting a booster battery in order to prevent sparks. To jump start (negative grounded battery):(1) Remove vent caps, (2) shield eyes, (3)connect ends of one cable to positive + terminals of each battery, (4) connect one end of other cable to negative (-) terminal of "good" battery, (5) connect other end of cable to engine block on vehicle being started (NOT TO NEGATIVE (-) TERMINAL OF BATTERY). To prevent damage to other electrical components on vehicle being started, make certain that engine is at idle speed before disconnecting jumper cables.

REMOVE CELL CAPS WHEN CHARGING OR USING JUMPER CABLES.

HIGH RATE OR CHARGE SCHEDULE

Charge rate 35 amperes, except use 5 ampere rate above 1.225.

Charge at low rate only until specific gravity reaches 1.250 at 80 degrees F.

If the specific gravity is below 1.125, use the indicated high rate of charge, then use a low rate of charge (5 amperes) until the specific gravity reaches 1.250 at 80 degrees F.

CHECK BATTERY FLUID LEVEL

Keep the fluid in each battery cell up to the level of the ring in the bottom of the filler well.

Ordinary tap water can be used except in areas where the water is known to be hard or to have a high mineral or alkali content—use distilled water in these areas.

Warning

Batteries contain SULFURIC ACID. In case of acid contact with skin, eyes, or clothing, FLUSH IMMEDIATELY WITH WATER FOR A MINIMUM OF FIVE MINUTES. Get "on-the-spot" medical attention immediately.

Hydrogen and oxygen gases are produced during normal battery operation. This gas mixture can explode if flames or sparks are brought near the battery. When charging or using battery in an enclosed space always provide ventilation.

Particular care should be used when connecting a booster battery in order to prevent sparks. To jump start (negative grounded battery):(1) Remove vent caps, (2) shield eyes, (3) connect ends of one cable to positive + terminals of each battery, (4) connect one end of other cable to negative (-) terminal of "good" battery, (5) connect other end of cable to engine block on vehicle being started (NOT TO NEGATIVE (-) TERMINAL OF BATTERY).

To prevent damage to other electrical components on vehicle being started, make certain that engine is at idle speed before disconnecting jumper cables.

REMOVE CELL CAPS WHEN CHARGING OR USING JUMPER CABLES.

CHECK BATTERY CABLES

Battery cables must be tight in terminals and terminals tight to posts after installation. A light coating of non-metallic grease can be applied to terminals and posts to retard corrosion and oxidation.

CHECK ALTERNATOR AND VOLTAGE REGULATOR OPERATION

Turn the headlights ON and check the charge indicator gauge or light to be sure the charging system is not discharging. If the system is discharging, check the charging system and repair as necessary. Refer to Part 31-01 in Volume 3.

MAINTENANCE

CLEAN AND TIGHTEN ELECTRICAL CONNECTIONS

Hard starting is often traceable to loose or corroded battery connections. A loose connection will overwork the generator/alternator and regulator and shorten their life.

1. Add water to battery cells to keep tops of plates covered.
2. Remove corrosion from around terminals. If severely corroded, scrub battery, terminals and surrounding area with a solution of baking soda and water. Use a nylon-bristle brush or other plastic brush that is impervious to acid. Wash off the residue from the battery and surrounding areas with clean water. Coat all corroded areas and terminals with petroleum jelly or chassis grease after installation.
3. Keep connections clean and tight. Prevent wire and lugs from touching each other or any metal except screw terminals to which they are attached.
4. Replace broken or worn wires and their terminals.
5. Have battery tested periodically. Follow battery manufacturer's instructions for maintenance.

G.P.D. CHARGING SYSTEM TESTS

Check the alternator drive belt and adjust it to specification before proceeding with any tests. Check and tighten all connectors at the starter relay and battery.

TESTS USING THE ROTUNDA ARE 20-22 ALTERNATOR REGULATOR TESTER

The general procedure is to connect the tester (Fig. 1) to the charging system, start the engine, make two tests, and then compare the pattern of lights that appear on the tester to each set of patterns shown on two charts (Figs. 2 and 3). Follow the instructions given with the ARE 20-22 tester.

TESTS USING THE ROTUNDA ARE 27-38 VOLT-AMP-ALTERNATOR TESTER

The following test procedures make use of the Rotunda Volt Amp-Alternator Tester ARE 27-38.

Refer to Wiring Diagram Manual Form 7795P-73 for schematics and locations of wiring harnesses. **Use care when connecting any test equipment to the alternator system, as the alternator output terminal is connected to the battery at all times.**

ALTERNATOR OUTPUT TEST ON ENGINE

When the alternator output test is conducted off the vehicle, a test bench must be used. Follow the procedure given by the test bench equipment manufacturer. **When the alternator is removed from the vehicle for this purpose always disconnect the battery ground cable as the alternator output connector is connected to the battery at all times.**

To test the output of the alternator on the vehicle, proceed as follows:

1. Check the alternator drive belt tension. Place the transmission in neutral or park **and apply the parking brake.** Make the connections and tester knob adjustments as shown in Fig. 4, Output Test. Be sure that the field rheostat knob is at the OFF position at the start of this test.
2. Close the battery adapter switch. Start the engine, then open the battery adapter switch.
3. Increase the engine speed to approximately 2000 rpm (use a tachometer). Turn off all lights and electrical accessories.
4. Turn the field rheostat knob clockwise until 15 volts is indicated on the voltmeter upper scale. Turn the master control knob clockwise until the voltmeter indicates between 11 and 12 volts. Holding the master control knob in this position, turn the field rheostat clockwise to its maximum rotation. Turn the master control knob counterclockwise until the voltmeter indicates 15 volts. Observe the ammeter reading. Add 2 amperes to this reading, to obtain alternator output. If rated output cannot be obtained, increase the engine speed to 2900 rpm and repeat this step.
5. Return the field rheostat knob to OFF, release the master control knob and stop the engine. Disconnect the test equipment, if no further tests are to be made.

If the alternator output is not OK, it will be necessary to remove the alternator from the vehicle and perform the necessary bench tests to locate the defect.

An output of 2 to 5 amperes below specifications usually indicates an open alternator diode. An output of approximately 10 amperes below specifications usually indicates a shorted alternator diode. An alternator with a shorted diode will usually produce a whine which will be most noticeable at idle speed.

MOTORCRAFT STATOR NEUTRAL VOLTAGE TEST—ON ENGINE

The Motorcraft alternator STA terminal is connected to the stator coil neutral, or off center point of the alternator windings. The voltage generated at this point is used to close the field relay in the Motorcraft charge indicator light system.

To test for the stator neutral voltage, disconnect the regulator. Make the connections and tester knob adjustments as shown in Fig. 5.

Start the engine and run it at 1000 rpm (use a tachometer). Turn off all lights and accessories. Rotate the field rheostat clockwise until at least 6 volts is indicated on the voltmeter upper scale. If 6 volts or more is not obtained, remove the alternator and perform the diode and stator tests to determine which part of the alternator is damaged.

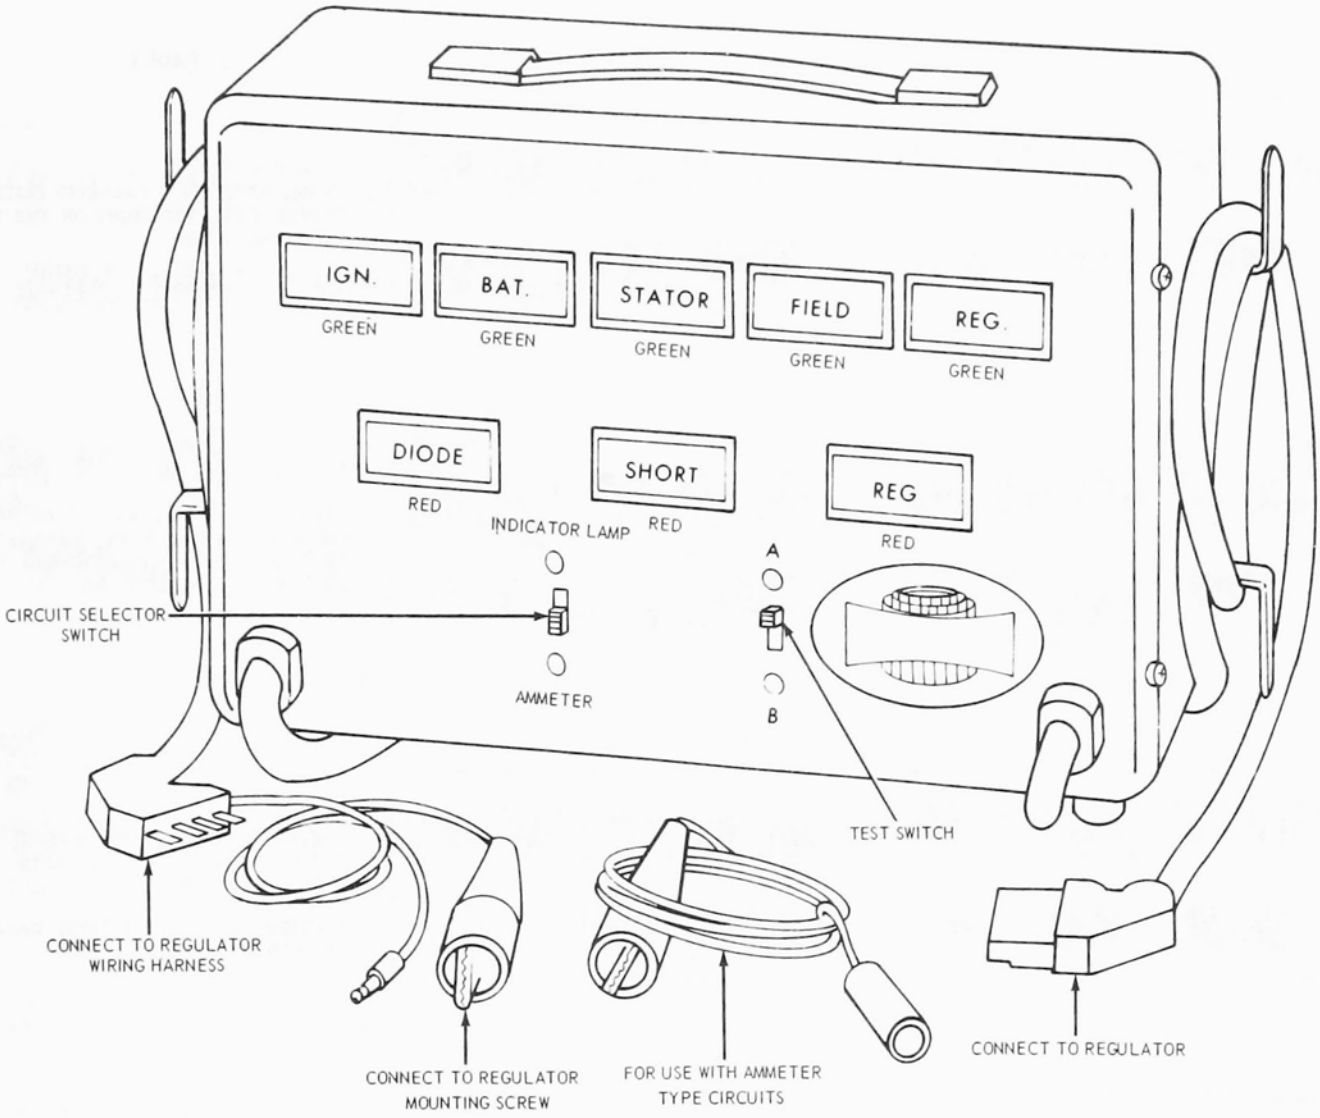

FIG. 1 ARE 20-22 Tester

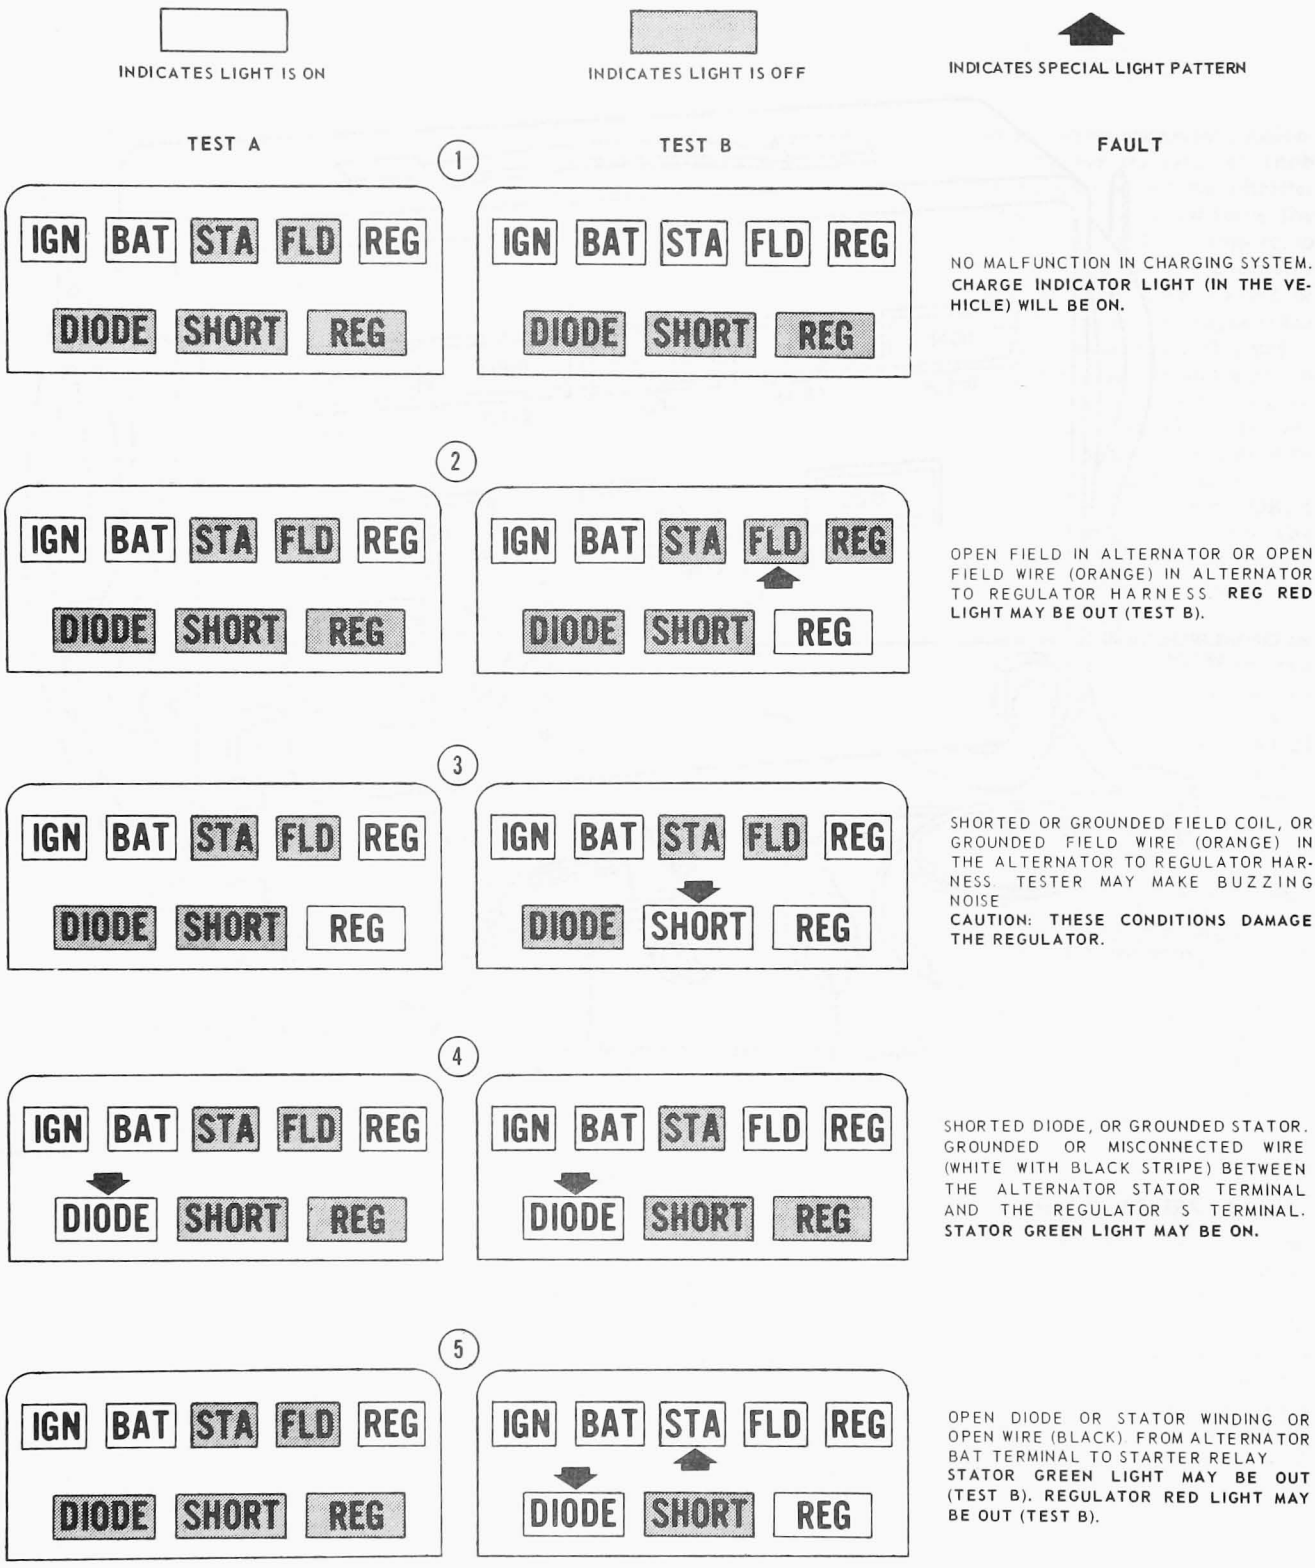

NOTE: ALWAYS REPAIR MALFUNCTION AND RETEST

Gauges Operation	32-01		
Headlight Alignment	32-01		

PRE-DELIVERY

WINDSHIELD WASHER RESERVOIR FLUID LEVEL

In warm weather, fill the reservoir with water and enough Rotunda windshield washer solvent to act as a detergent.

In winter, be sure to keep the reservoir filled with a solution of 2 parts water to 1 part Ford windshield washer solvent. This solution is necessary to prevent freezing and damaging the reservoir.

HEADLIGHT ALIGNMENT

Check the headlights for proper alignment. If necessary, align the headlights using the Headlight Aiming Kit—Model T.R.E. 540. Be sure to use the latest manufacturers instructions, dated June 1971.

INSTALL RADIO ANTENNA

Check type and location specified, and install the antenna using installation instructions and template supplied with antenna kit. Do not break the plastic adapter when tightening the nut.

RADIO

Check for proper operation of radio, if so equipped. Set push-buttons for local stations.

CHECK OPERATION OF ALL LIGHTS, GAUGES AND INSTRUMENTS

Check for proper operation of switches and brightness of lights, including operation of oil pressure and alternator warning lights. Check detent action and return of turn signal lever by making full left and right turns during road test. Check all other lights and switches for proper operation.

CHECK SPEEDOMETER, ODOMETER AND TACHOMETER

Check the speedometer, odometer and tachometer for proper operation. Lubricate and tighten cable connections if needle bounce is found.

HORN, WINDSHIELD WIPERS AND WASHERS

Check for proper operation, including sweep and park (Figs. 1 and 2). Adjust if required. Check the windshield washer spray pattern. Adjust if required (Refer to Group 35 of Volume 3).

INSTALL AND CHECK CIGAR LIGHTER

Install the lighter and check the operation of the lighter. If the lighter is inoperative, check to be sure the wire is connected to the light socket.

HEATER AND DEFROSTER

Check for proper operation by placing selector in heat position. Actuate blower switch through each speed position and check for corresponding change in air discharge at outlets. Move temperature control lever through entire range and check for proper change in discharge air temperature. Repeat this procedure in defrost position and check for proper air discharge through defroster nozzles.

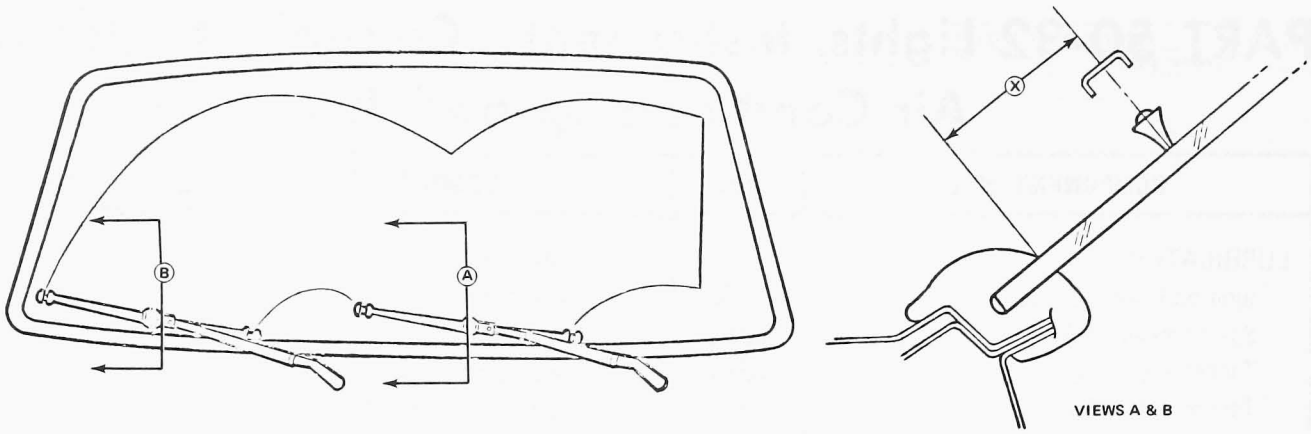

FIG. 1 Wiper Arm and Blade Adjustment

Vehicle	Dimension X (Inches)	
	Driver's Side	Passenger Side
C-Series (Para-Wipe)	1.75-2.75	1.75-2.75
C-Series	1.00-2.00	1.00-2.00
W-Series	1.00-2.50	1.00-2.50
L-Series	2.00-3.38	1.50-2.87
Econoline	2.50-3.50	2.50-3.50
Bronco (From Top)	0.50-1.25	0.50-1.25
F-Series	1.00-2.00	1.00-2.00

CK3042-A

FIG. 2 Wiper Arm and Blade Adjustment x Dimensions

FRESH AIR VENTS

Check for proper operation of all fresh air vents by actuating the vent controls.

AIR CONDITIONING

Check for proper operation by placing the control levers in Max. A/C and Cool positions. Increase engine speed to approximately 1500 rpm. After approximately 1 minute, check for proper cool air discharge at each A/C register in each blower speed position. Also, check register(s) for direction and volume control. Check for proper temperature modulation by moving control lever slowly to Warm position. Then, return lever to Cool position.

LUBRICATION

LUBRICATE IGNITION LOCK

Check for ease of operation by inserting key and turning to all positions. Remove key and lubricate ignition lock cylinder if necessary with the specified lock lubricant (Part 50-03). Insert key and operate several times to be sure lubricant has effectively worked in. Remove key and wipe off any excess lubricant.

LUBRICATE SPEEDOMETER CABLE

1. Disconnect the speedometer cable from the speedometer.
2. Pull the core out of the casing.
3. Wash all old lubricant from the cable. Wipe the cable dry.
4. Apply a thin film of specified Speedometer Cable lubricant (Part 50-03) to the cable.
5. Insert the core in the casing.
6. Connect the cable to the speedometer.

LUBRICATE TACHOMETER CABLE

1. Disconnect the tachometer cable from the tachometer head.
2. Pull the core out of the casing.
3. Wipe off all the old lubricant from the cable and apply specified Speedometer Cable Lubricant (Part 50-03) sparingly.
4. Install the tachometer cable core in the cable casing and connect the cable to the tachometer head.

LUBRICATE TACHOMETER ADAPTER—C-LN-AND W-Series

Disconnect the cable housing at both ends of the adapter. Daub the cable ends liberally with Ford All-Purpose Lubriplate, insert them into the adapter and reconnect the cable housings.

MAINTENANCE

REPLACE WINDSHIELD WIPER BLADES

Wiper blade replacement intervals will vary with the amount of use, type of weather, chemical reaction from road tars or salts and the age of the blades. Be sure that the windshield glass surface is not contaminated with oil, tree sap or other foreign substance which cannot be easily rubbed off.

Generally, if the wiper pattern across the glass is still uneven and streaked after these tests, the blades should be replaced.

WINDSHIELD WASHER RESERVOIR FLUID LEVEL

In warm weather, fill the reservoir with water and enough Rotunda windshield washer solvent to act as a detergent.

In winter, be sure to keep the reservoir filled with a solution of 2 parts water to 1 part Ford windshield washer solvent. This solution is necessary to prevent freezing and damaging the reservoir.

HEADLIGHT ALIGNMENT

Check the headlights for proper alignment. If necessary, align the headlights using the Headlight Aiming Kit—Model T.R.E. 540. Be sure to use the latest manufacturers instructions, dated June 1971.

PRE-DELIVERY

CHECK SEAT CONTROL

Check lever for ease of operation, test freeness of seat movement on track, and test for solid engagement with lever released. If equipped with a suspension seat, check for proper operation of all controls.

SEAT BACK LATCH

Check the seat back latches (if so equipped) for ease of operation and seat back retention.

WINDOWS AND VENTS

Check for ease of operation, like position of both right and left interior handles, and tight fit against weatherstrip when closed. Check for alignment to opening. Refer to 1973 Truck Shop Manual, Group 42, for detailed instructions.

CHECK EXTERIOR FOR FITS AND APPEARANCE

Inspect the body exterior for objectionable door and hood gaps or evidence of rubbing or binding with adjacent panels. Check the exterior mouldings for adequate retention and/or extreme misalignment. Inspect the bumpers for an objectionable alignment appearance.

CHECK DOORS, LOCKS AND LATCHES FOR OPERATION

Open and close all doors from both inside and outside the vehicle. Check for ease of operation, proper latching, and alignment of the latch and striker. Check to be sure all doors can be locked and unlocked from inside the vehicle. Check to be sure the doors can be locked and unlocked from outside the vehicle with a key.

CHECK TAILGATE OPERATION

Check the tailgate for ease of operation and lubricate as required. Check the latch alignment and adjust if necessary. Refer to the 1973 Truck Shop Manual, Group 44, for detailed adjustment procedures.

BUMPERS AND MOULDINGS

Check condition, fit and alignment. Adjust as required. Refer to the 1973 Truck Shop Manual, Group 47, for detailed instructions.

FRONT BUMPER BOLT TORQUE

Check and tighten as required, to specifications given in Specifications Section.

REMOVE SHIPPING PROTECTIVE MATERIAL

Remove all shipping protective covers from the vehicle except the tape under the hood flange on L-Series trucks. **This tape should not be removed.**

CLEAN AND INSPECT VEHICLE

Remove the windshield markings and tapes. Wash the vehicle and check for leaks. Inspect for exterior metal damage. Inspect exterior paint condition, and touch up chips and scratches. Check for excess sealer.

AFTER ROAD TEST

Remove the seat protector and tapes. Inspect for interior paint condition, and touch up chips and scratches. Check for soft trim soilage and excess sealer.

Verify information on ownercard with warranty plate and check Owner's Manual in glove compartment.

LUBRICATION

LUBRICATE HOOD LATCH AND HINGES

Spray Specified Polyethylene grease (Part 50-03) on all pivot points and on the striker plate as required to eliminate any binding condition. Operate the latch mechanism several times to be sure that the lubricant has effectively worked in.

LUBRICATE HOOD AUXILIARY CATCH

Spray Specified Polytheylene Grease (Part 50-03) on all pivot points as required to eliminate any binding conditions. Operate the catch several times to be sure that the lubricant has effectively worked in.

LUBRICATE LOCK CYLINDERS

Apply Specified Lock Lubricant (Part 50-03) sparingly through the key slot. Insert the key and operate the lock several times to be sure that the lubricant has effectively worked in.

LUBRICATE DOOR HINGE, HINGE CHECK, ROTOR AND STRIKER PLATE

Spray Ford Polythylene Grease (Part 50-03) on the hinge pivot points, rotor, and striker plate as required to eliminate any binding condition. Open and close the door several times to be sure that the lubricant has effectively worked in.

LUBRICATE TAILGATE HINGE

Spray Specified Polythylene Grease (Part 50-03) on all pivot and friction points to eliminate any binding conditions. Operate the tailgate several times to be sure that the lubricant has effectively worked in.

LUBRICATE CAB LATCH (W-SERIES)

Squirt 10W oil into the cab lower latch to lubricate the locking cams (Fig. 1).

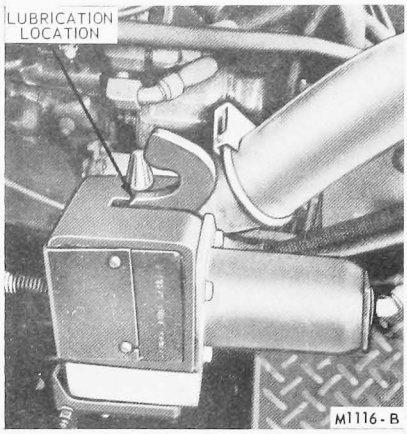

FIG. 1 Cab Latch Lubrication—W-Series

LUBRICATE CAB LATCH MECHANISM—C-SERIES

Lubricate the lock handle linkage and locking cams with 10W oil at all pivot points. Operate the mechanism to work the lubricant into all points.

MAINTENANCE

CLEAN BODY AND DOOR DRAIN HOLES

Drain holes, located along the bottom surface of the door and side panels, should be inspected periodically for plugged or obstructed condition. A practical time for inspection is whenever the vehicle is washed. Use a small screwdriver or similar tool to clean these drain holes.

SPECIFICATIONS

FRONT BUMPER BOLTS TORQUE

3/8 Inch	30–40 Ft-Lbs.
7/16 Inch	50–70 Ft-Lbs.
9/16 Inch	80–90 Ft-Lbs.
1/2 Inch	75–105 Ft-Lbs.
5/8 Inch	140–180 Ft-Lbs.
